7   China

8   **Abstract:** The main challenge of capacitor is how to reconcile the contradiction of  
9   lowering the dielectric loss while maintaining high dielectric constant of polymer  
10   based composites. In this work, a novel two-phase ferroelectric polymer composite,  
11   consisting of semiconductive bismuth sulfide (Bi<sub>2</sub>S<sub>3</sub>) nanorods and poly(vinylidene  
12   fluoride) (PVDF) matrix, was fabricated by a sequence of casting, hot-stretching and  
13   hot-pressing techniques. Orderly polymer composites based on PVDF assembled with  
14   parallel aligned Bi<sub>2</sub>S<sub>3</sub> nanorods were realized in the composites after a  
15   hot-stretching-pressing process. It's interesting to note that those orderly polymer  
16   composites exhibit excellent dielectric properties. Results show that the composites  
17   with oriented structure have high dielectric constant and unusual low dielectric loss.  
18   The parallel aligned Bi<sub>2</sub>S<sub>3</sub> nanorods along the tensile-strain direction could be charged  
19   with the improvement of dielectric properties of the composites. This study also  
20   provides an extremely useful method to reduce the dielectric loss of similar kind of  
21   composites.

## 24 1. Introduction

25 The polymer-matrix composites filled with inorganic particles such as  
26 ferroelectric ceramic <sup>1,2</sup> and metal particles <sup>3,4</sup> have attracted great attention due to  
27 their easy processing and flexibility for various potential applications such as  
28 embedded capacitors, actuators, and printed circuit boards <sup>5-7</sup>. Xu et al. prepared the  
29 semiconductor composites by mixing PVDF and various conductive fillers were  
30 investigated with regard to the dielectric constant as a function of frequency,  
31 temperature and the concentration of fillers<sup>8</sup>. Poly (vinylidene fluoride) (PVDF),  
32 which is flexible, easy to process and shows excellent electric breakdown properties,  
33 has become the subject of many intensive investigations for their broad applications in  
34 electromechanical systems <sup>9,10</sup>.

35 Many studies show that dielectric constant would be largely enhanced when  
36 mental and/or ceramic fillers were employed into the polymer based composites <sup>11-15</sup>.  
37 Dang et al. have prepared high-K CCTO/PI functional hybrid films, a high dielectric  
38 constant (49) is obtained at 10<sup>2</sup> Hz when the concentration of the CCTO filler reaches  
39 40 vol%<sup>16</sup>. But the researchers note that, the reliability is of great importance for  
40 capacitor. Therefore, it is urgent to seek a kind of material, which can achieve high  
41 dielectric constant and low dielectric loss at low content. One important approach to  
42 improve the dielectric properties of composites is incorporating ceramic nanoparticles  
43 into polymer matrix to enhance their relatively permittivities. For instance, L. Zhang

44 et al. have prepared BST–P(VDF–CTFE) 0–3 nanocomposites, for the composites  
45 with 40 vol% of BST, a dielectric constant of 70 with a loss of 0.07 at 1 kHz is  
46 obtained at room temperature<sup>17</sup>. Sodano et al. reported a BaTiO<sub>3</sub> nanowires/PVDF  
47 composite with a dielectric constant of about 44.3, when the concentration of the  
48 conducting filler is 30 vol%<sup>18</sup>. However, the volume fraction of ceramic particles is  
49 usually very high, which will do great damage to the mechanical properties of  
50 polymer based composites<sup>19</sup>.

51 To overcome the above shortcoming, inorganic conductors are often employed to  
52 increase the dielectric constant of polymer matrix based on the percolation theory<sup>20</sup>.  
53 However, the corresponding loss and leakage current of these composites are too high  
54 to meet the requirements of realistic applications. The one-dimensional fillers caused  
55 wide attention because of their large aspect ratio<sup>21</sup>, so that the composites with these  
56 fillers can reach the percolation threshold at low content. Zhang et al. found that the  
57 fitting constant  $f_c$  increases with increasing frequency and they believed that this  
58 arises from the critical phenomenon,  $\epsilon_{eff} \propto f^{\gamma-1}$ , for composites close to the  $f_c$ <sup>22</sup>. Nan  
59 et al. reported the dielectric properties of PVDF/ Bi<sub>2</sub>S<sub>3</sub> nanorod (nr- Bi<sub>2</sub>S<sub>3</sub>) composites  
60 and the dielectric constant can reach 160<sup>23</sup>. However, it is found that the dielectric  
61 loss of these percolative composites is usually quite high. Because the nanoscale  
62 fillers with large aspect ratio are partial to connect each other and form a conductive  
63 network with the increasing of conduct fillers, which would be blamed for the electric  
64 leakage loss. At the low frequency, the electric leakage could be considered to make  
65 the major contribution to the dielectric loss<sup>24</sup>. As a result, the dielectric loss of these

66 percolative composites is usually high when the percolation threshold was achieved<sup>25</sup>.  
67 And what really impacts the practical use of these percolative composites materials is  
68 dielectric loss, which is rarely mentioned and deserves more attention.

69 Therefore, the main challenge is how to reconcile the contradiction of lowering  
70 the dielectric loss while maintaining high dielectric constant. There are many methods  
71 to lower the dielectric loss of nanocomposites, such as, treating the nanoparticles with  
72 coupling agents<sup>26,27</sup>; fabricating nanocomposites via in situ olefin polymerization and  
73 employing core@shell structured fillers. Xie et al. successfully lower the dielectric  
74 loss of polymer nanocomposites by using core–satellite structured ultra-small silver  
75 (Ag) decorated barium titanate (BT) nanassemblies<sup>28</sup>. Nowadays, structure design, as  
76 a new method to improve the dielectric properties of polymer composites has been  
77 draw wide attention. Our previous results showed that the addition of Bi<sub>2</sub>S<sub>3</sub> could  
78 enhance the dielectric properties of the PVDF and polyethylene (PE)<sup>29,30</sup>. We also  
79 have fabricated an orderly polymer composite with zinc flakes (ZFs) oriented parallel  
80 in the PVDF, which obtained high dielectric constant of 176 but low loss of 0.06 at  
81 10<sup>3</sup> Hz<sup>31</sup>. Along this line, we expect to prepare one-dimensional directional  
82 composites by structure design, which has high dielectric constant and low dielectric  
83 loss at low content.

84 Tensile strain is usually employed to enhance the tensile strength and modulus of  
85 polymer composites<sup>32</sup>. Very few studies have been focused on the effect of tensile  
86 strain on dielectric properties. Yao et al. studied the tensile strain's effect on the  
87 dielectric properties of multiwall carbon nanotube (MWNT)/poly(vinylidene fluoride)

88 (PVDF) nanocomposites, the maximum increment in the dielectric constant of the  
89 composite can reach 30% at  $10^2$  Hz relative to that before stretching<sup>33</sup>. Dang et al.  
90 have studied the effect of tensile strain on morphology and dielectric property in  
91 nanotube/polymer nanocomposites<sup>34</sup>, the dielectric constant and conductivity always  
92 decreased after the composites were stretched. So in this work, the novel but simple  
93 method (hot-stretching and hot-pressing) is developed to lower the dielectric loss of  
94 the two-phase  $\text{Bi}_2\text{S}_3$ /PVDF composites while maintaining the high dielectric constant.  
95 By designing such a one-dimension well-aligned parallel structure, a significant  
96 reduction in dielectric loss of the novel two-phase  $\text{Bi}_2\text{S}_3$ /PVDF composite is observed,  
97 while the dielectric constant remains a high level at a lower content.

## 98 **2. Materials and methods**

99  $\text{Bi}_2\text{S}_3$  nanorods were synthesized by a hydrothermal method<sup>35</sup>. All  $\text{Bi}_2\text{S}_3$   
100 nanorods in this work were treated by surfactant  $\gamma$ -aminopropyltriethoxysilane  
101 (KH550). The composites were prepared by a simple solution-casting, hot-stretching  
102 and hot-pressing method. First, a desired amount of  $\text{Bi}_2\text{S}_3$  nanorods was  
103 ultrasonicated in 20 ml N, N-dimethylformamide (DMF) solvent for 30min, and at the  
104 same time, a certain amount of PVDF was dissolved in N, N-dimethylformamide  
105 (DMF) at room temperature. Next, PVDF solution was added into  $\text{Bi}_2\text{S}_3$  suspension  
106 solution when the latter was stirred. The mixture was further stirred for 2h, and  
107 ultrasound was applied to the suspension more than one time in order to prevent the  
108 agglomeration of  $\text{Bi}_2\text{S}_3$  nanorods. Then the composite films were made by the  
109 solution casting machine at 80 °C, using glass as substrate. The resultant films were

110 stretched about 4 times along the casting direction at 160 °C. Finally, the Bi<sub>2</sub>S<sub>3</sub>/PVDF  
111 films were cut into 10×10 mm pieces, these little pieces of the oriented samples (O-S)  
112 were stacked up along the tensile strain direction (the disoriented samples (D-S) with  
113 no direction) into the hot-press mould, the bulk samples were made by a simple  
114 hot-pressing method at 200 °C, under 4 MPa (heated for 10 min at the same  
115 temperature, pre-pressed for 15 min, released for a while, and then re-pressed for 15  
116 min, followed by cooling to room temperature under the same pressure). For electrical  
117 measurement, silver electrodes were painted on both sides of the samples.

118 The fractured surface morphology of the samples was examined by scanning  
119 electron microscopy (FEI Siron 200). The dielectric properties were measured by  
120 employing an Agilent 4294A Impedance analyzer in the frequency ranges of 100  
121 Hz–10 MHz at room temperature. The out-of-plane dielectric properties of the  
122 nanocomposites were studied in this work.

### 123 **3. Results and discussion**

124

125 Fig. 1. SEM images of (a)  $\text{Bi}_2\text{S}_3$  nanorods; and cross-section views of oriented or disoriented  
 126  $\text{Bi}_2\text{S}_3/\text{PVDF}$  composites with different  $f_{\text{Bi}_2\text{S}_3}$ : (b) 2 % O-S; (c) 2 % D-S; (d) 4 % O-S; (e) 2 % O-S  
 127 (another direction); (f) 10 % O-S.

128  $\text{Bi}_2\text{S}_3$  nanorods were synthesized by a hydrothermal method. The SEM  
 129 micrograph of  $\text{Bi}_2\text{S}_3$  nanorods and  $\text{Bi}_2\text{S}_3/\text{PVDF}$  composites are shown in Fig. 1. From  
 130 Fig. 1a, the hydrothermal synthesized products mainly consist of various sizes of  
 131  $\text{Bi}_2\text{S}_3$  nanorods with lengths of 0.4–1  $\mu\text{m}$  and diameters of 80–100 nm, and the aspect  
 132 ratio is about 10.

133 The composite films were fabricated by casting procedure at 80  $^\circ\text{C}$ . The  
 134 cross-section micrograph Fig. 1(b-c) of the composite samples demonstrate that the  
 135  $\text{Bi}_2\text{S}_3$  nanorods are homogeneously dispersed into the PVDF matrix without serious  
 136 aggregation at low  $\text{Bi}_2\text{S}_3$  nanorods content, i.e.,  $f_{\text{Bi}_2\text{S}_3}=2$  vol%. However, as  $f_{\text{Bi}_2\text{S}_3}$   
 137 increases, some  $\text{Bi}_2\text{S}_3$  aggregates emerge, as shown in Fig. 1d ( $f_{\text{Bi}_2\text{S}_3}=4$  vol%) and Fig.  
 138 1f ( $f_{\text{Bi}_2\text{S}_3}=10$  vol%). The films were stretched along the casting direction at 160  $^\circ\text{C}$ .

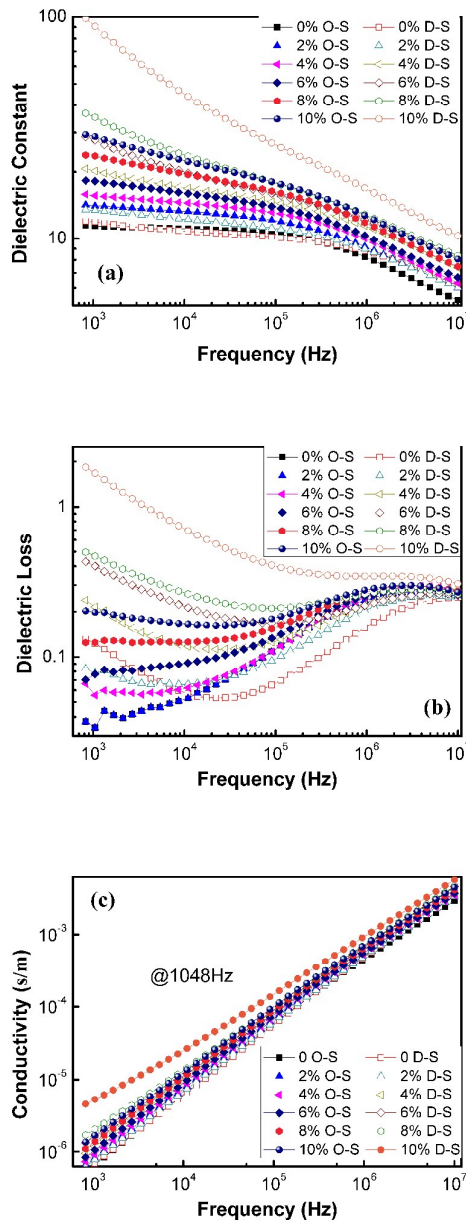

139 After been stretched, the nanorods have preferential orientations in the direction  
140 parallel to the tensile strain, which could be clearly seen in the cross-section  
141 micrograph Fig. 1(b, d, and f).

142 As shown in Fig. 1e, numerous cross surface of  $\text{Bi}_2\text{S}_3$  nanorods could be noticed,  
143 and whole nanorods can barely be seen in the picture because this cross-section is  
144 perpendicular to the tensile-strain direction. The holes in this picture should be  
145 attributed to the extraction of the  $\text{Bi}_2\text{S}_3$  nanorods, because the size of the hole is  
146 basically consistent with the diameter of the  $\text{Bi}_2\text{S}_3$  nanorods and there are no clear  
147 holes in Fig. 1b. By contrast, no preferential orientations of  $\text{Bi}_2\text{S}_3$  nanorods could be  
148 observed in the disoriented samples (D-S) (see Fig. 1c). Due to the big difference of  
149 the tensile strength and modulus of the PVDF matrix and  $\text{Bi}_2\text{S}_3$  nanorods fillers, the  
150 stretching process will do great damage to the interface between the matrix and the  
151 fillers of the nanocomposite and decreased the dielectric properties. But there are no  
152 clearly defects can be seen in Fig.1b at low  $\text{Bi}_2\text{S}_3$  nanorods content, which explain  
153 that the hot-stretching process can fix the defects at high temperature above PVDF  
154 viscoelastic temperature. In the hot-stretching process, we call this phenomenon as the  
155 effect of “self-repairing” when the matrix material (PVDF) is at its viscoelastic  
156 temperature.

157 From Fig. 1 we can draw a conclusion that the tensile strain played a crucial role  
158 in deciding the morphology of  $\text{Bi}_2\text{S}_3/\text{PVDF}$  nanocomposites. After that, a pressure at  
159  $200^\circ\text{C}$  was added along the direction perpendicular to the film plane when the film  
160 was cut into pieces, and then were stacked up along the tensile strain direction (the

161 disoriented samples with no direction) into the hot-press mould. The hot-pressing  
 162 progress could effectively reduce the bubble defect in the composite.

163

164

165

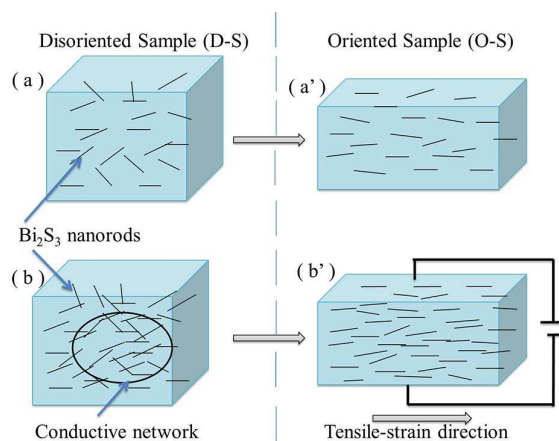

166 Fig. 2. Frequency-dependence of: (a) dielectric constant, (b) dielectric loss and (c)  
 167 conductivity of the oriented and disoriented  $\text{Bi}_2\text{S}_3/\text{PVDF}$  composites with different  $f_{\text{Bi}_2\text{S}_3}$  at room  
 168 temperature.

169 Fig. 2 shows the dependences of dielectric constant, dielectric loss and

170 conductivity of the  $\text{Bi}_2\text{S}_3/\text{PVDF}$  composites with different concentrations of  $\text{Bi}_2\text{S}_3$   
171 nanorods with oriented structure and disoriented structure on frequency at room  
172 temperature. A conclusion can be drawn that the dielectric constant, dielectric loss and  
173 conductivity of the composites always increased with the increasing  $\text{Bi}_2\text{S}_3$  nanorods,  
174 whether the  $\text{Bi}_2\text{S}_3$  nanorods are oriented or not. The dielectric constant of the  
175 composites always decreased with the increasing frequency, while the conductivity is  
176 increased. At low frequency range, according to the interfacial polarization or  
177 Maxwell–Wagner–Sillars effect<sup>36</sup>, because of the different relaxation time of the  
178 PVDF and  $\text{Bi}_2\text{S}_3$  nanorods, lots of free charge carriers generated by surface  
179 polarization are blocked at the interfaces between  $\text{Bi}_2\text{S}_3$  nanorods and PVDF matrix,  
180 and lots of dipoles form on the  $\text{Bi}_2\text{S}_3$  nanorods. The inertia of formed dipoles makes  
181 the polarization spend much more time than other dielectric process, thus, the  
182 interfacial polarization occurs at low frequency, and dielectric constant and loss  
183 decrease rapidly when frequency increases. At high frequency range, the electrical  
184 properties of the composites are dominated by the PVDF. Therefore, the dielectric  
185 constant is comparatively independent of frequency and is generally lower than that at  
186 low frequency, and the dielectric properties of the  $\text{Bi}_2\text{S}_3/\text{PVDF}$  nanocomposites  
187 change little by the tensile strain at high frequency.

188 Fig. 3 shows the schematic images of how tensile-strain effects the  $\text{Bi}_2\text{S}_3$   
189 nanorods distribution in polymer composites. The (a) and (a') is disoriented and  
190 oriented samples at low content filling, while (b) and (b') is disoriented and oriented  
191 samples at high content filling, respectively. Because the  $\text{Bi}_2\text{S}_3$  nanorod was an

192 anisotropic rod material with a large aspect ratio, the nanorods would be rearranged  
 193 along the tensile-strain direction when the  $\text{Bi}_2\text{S}_3/\text{PVDF}$  composites are stretched. This  
 194 mechanism has been verified by the SEM micrographs as is shown in Fig. 1.  
 195

196  
 197 Fig. 3. Schematic images of  $\text{Bi}_2\text{S}_3$  nanorods distribution in polymer composites at low content  
 198 filling (a) and (a') and high content filling (b) and (b') of  $\text{Bi}_2\text{S}_3$  nanorods with disoriented structure  
 199 (a) and (b) and oriented structure (a') and (b'), respectively.

200 It is well known that the enhancement of dielectric constant in the low frequency  
 201 range is mainly due to the contribution of interfacial polarization associated with the  
 202 entrapment of space charges at the interfaces of fillers and matrix. Therefore, the  
 203 anisotropic dielectric constant could be ascribed to the anisotropic intensity of  
 204 interfacial polarization. According to the theory of dielectrics, the polarization  
 205 intensity  $P$  is defined as<sup>31</sup>

$$206 \quad P = \frac{\sum \mu}{V} = \frac{\sum ql}{V} \quad (1)$$

207 where  $\mu$  stands for the dipolar moment,  $V$  corresponds to the volume of the sample,  $q$   
 208 and  $l$  are denoted as positive or negative charge and the displacement between  
 209 positive and negative charges under external electric field, respectively. In the case of  
 210 interfacial polarization, positive or negative space charge  $q$  and volume  $V$  of a given

211 cubic sample are considered as constants independent of directions.

212 As is shown in Fig. 3, after been stretched, the distance between the  $\text{Bi}_2\text{S}_3$   
213 nanorods is greatly reduced in the direction of perpendicular to the tensile strain.  
214 Therefore, the displacement  $l$  of the oriented samples is obviously higher than that of  
215 the disoriented samples in the perpendicular direction, which leading to the stronger  
216 intensity of interfacial polarization and higher dielectric constant. Simultaneously,  
217 with the increase of  $\text{Bi}_2\text{S}_3$  nanorods, a fast increase of dielectric constant can be found  
218 in the disoriented samples (see Fig. 4a).

219 According to the percolation theory, when  $f_{\text{Bi}_2\text{S}_3}$  is less than  $f_c$ , the dielectric  
220 constant ( $\epsilon$ ) near the percolation threshold can be characterized by the power law<sup>20,37</sup>,  
221 as follows:

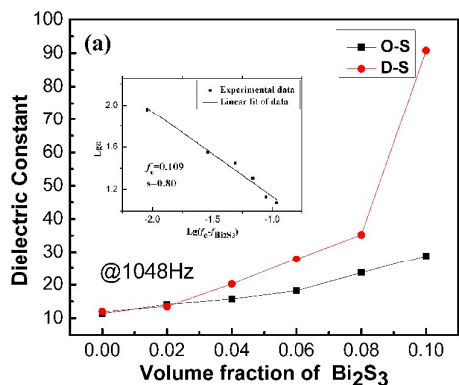

$$222 \quad \epsilon(f_{\text{Bi}_2\text{S}_3}) \propto (f_c - f_{\text{Bi}_2\text{S}_3})^{-s} \quad \text{as } f_{\text{Bi}_2\text{S}_3} < f_c \quad (2)$$

223 where  $s$  is the dielectric critical exponent. For disoriented samples, the inset in Fig.  
224 4(a) shows that the linear fit of the experimental data according to Eq. (2) and  $f_c$   
225 =10.9% and  $s=0.80$ , and  $s$  agrees well with the universal value (0.7-1). As for oriented  
226 samples, the percolation threshold is very large, which can be clearly seen in Fig. 4(a).

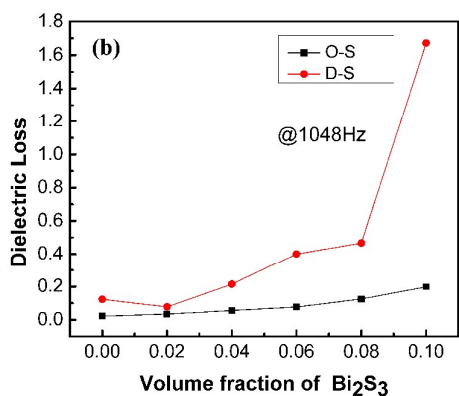

227 See from Fig. 4, at 1048 Hz, with the increasing of the concentration of  $\text{Bi}_2\text{S}_3$   
228 nanorods, the differences of dielectric constant and dielectric loss between the  
229 oriented and disoriented composites become more significant. At 1048 Hz, for  $f_{\text{Bi}_2\text{S}_3}=4$   
230 vol%, the dielectric loss of the disoriented sample is 0.21472 which is about 3 times  
231 higher than that of oriented sample (0.05561). However, when  $f_{\text{Bi}_2\text{S}_3}$  increases to 10  
232 vol%, the dielectric loss of the disoriented sample is 1.672 which is almost 9 times of

233 that of the oriented sample (0.1975).

234 The conductive network is very important to improve the dielectric constant as  
235 well as dielectric loss of composites. When  $f_{\text{Bi}_2\text{S}_3}$  is low, most of the  $\text{Bi}_2\text{S}_3$  nanorods  
236 are fully dispersed in the matrix without serious aggregation, which may be due to the  
237 solvent evaporation process. Tensile strain cannot do much under this circumstance,  
238 so the change of the dielectric properties of these two series composites are not  
239 obvious (see Fig. 4). But the  $\text{Bi}_2\text{S}_3$  nanorods begin to connect to each other and form a  
240 conductive network with the increasing of the volume content. In this case, the  
241 conductive network would be destroyed by the tensile strain, because the  $\text{Bi}_2\text{S}_3$   
242 nanorods prefer to stay along the tensile strain direction and parallel to each other  
243 when the tensile strain is employed, which decrease the chance to connect each other.

244

245

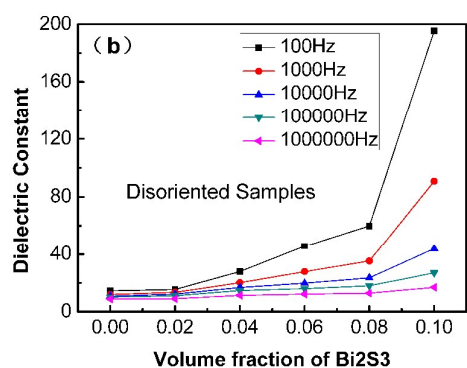

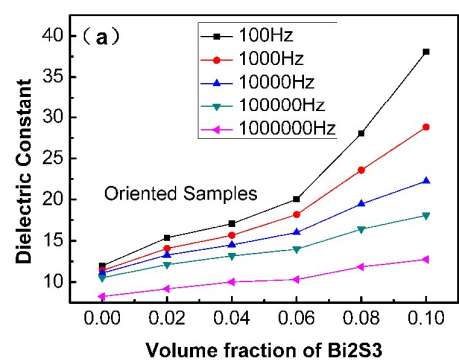

246

247 Fig. 4. At 1048 Hz, the dependence of (a) dielectric constant, and the inset in (a) presents the best  
 248 fitting of dielectric constants of disoriented samples according to Eq. (1); (b) dielectric loss and (c)  
 249 conductivity of the oriented and disoriented Bi<sub>2</sub>S<sub>3</sub>/PVDF composites on the  $f_{\text{Bi}_2\text{S}_3}$ , measured at  
 250 room temperature.

251 There is a gradual enhancement of dielectric constant with increasing  $f_{\text{Bi}_2\text{S}_3}$  with  
 252 low loading of Bi<sub>2</sub>S<sub>3</sub> nanorods. However, when  $f_{\text{Bi}_2\text{S}_3} > 0.08$ , both the dielectric  
 253 constant and dielectric loss of the disoriented composites have a dramatic  
 254 enhancement, while the oriented composites don't have. With the increasing Bi<sub>2</sub>S<sub>3</sub>  
 255 nanorods, the conductive phase Bi<sub>2</sub>S<sub>3</sub> nanorods began to connect, and form the  
 256 conductive network where the dielectric constant abruptly increases. When the  
 257 conductive network formed, the leakage current increased dramatically, so the  
 258 dielectric loss also abruptly increased. Because of the tensile strain, the oriented  
 259 composites did not appear this phenomenon. The oriented composites need much

260 more  $\text{Bi}_2\text{S}_3$  nanorods to form the conductive network, which means the hot-stretching  
 261 process delayed the percolation threshold of the composites. This could be explained  
 262 by the rearrangement of  $\text{Bi}_2\text{S}_3$  nanorods in the composites which destroyed the  
 263 network structures. In this case, numerous clusters were broken off, and subsequently  
 264 the  $\text{Bi}_2\text{S}_3$  nanorods were rearranged along the tensile-strain direction as a preferential  
 265 orientation. Namely, numerous  $\text{Bi}_2\text{S}_3$  nanorods in the composites were parallel to the  
 266 tensile-strain direction after stretched. As a result, the dielectric constant and  
 267 conductivity of  $\text{Bi}_2\text{S}_3/\text{PVDF}$  nanocomposites decreased significantly.

268

269

270 Fig. 5 The change in dielectric constant with the filled content of  $\text{Bi}_2\text{S}_3$  nanorods at different  
 271 frequencies.

272 The change in dielectric constant with the filled content of  $\text{Bi}_2\text{S}_3$  nanorods at

273 different frequencies is shown in Fig. 5. The dielectric constant increases with the

274 increasing  $f_{\text{Bi}_2\text{S}_3}$  at all considered frequencies, which is due to the conductivity  
275 increase of semiconductive  $\text{Bi}_2\text{S}_3$  nanorods. As the frequency increases, the dielectric  
276 constant increases slowly for these two kinds of composites. At low frequency, the  
277 molecules have enough time for polarization. However, at high frequency, the  
278 polarization of molecules does not have enough time to catch up with the change in  
279 electrical field frequency, which leads to the weak dependence of dielectric constant  
280 on the filled content<sup>29</sup>. Compare Fig. 5a with Fig. 5b, we can draw that the dielectric  
281 constant of the D-S decreased more intense than that of the O-S, as we have mentioned  
282 before.

#### 283 4. Conclusions

284 In summary, orderly polymer composites based on PVDF assembled with parallel  
285 aligned  $\text{Bi}_2\text{S}_3$  nanorods were prepared by simple and robust techniques of hot  
286 stretch-pressing process. It's interesting to note that those orderly polymer composites  
287 indicate excellent dielectric properties with high dielectric constant and unusual low  
288 dielectric loss. The dielectric loss of the two-phase  $\text{Bi}_2\text{S}_3/\text{PVDF}$  composite decreased  
289 after the composites were stretched, while the dielectric constant still remains at high  
290 level. The dielectric loss of the 4 vol% oriented sample (O-S,  $f_{\text{Bi}_2\text{S}_3}=4$  vol%) is  
291 lowered from 0.21472 to 0.05561 at 1048Hz due to the orientation of the  $\text{Bi}_2\text{S}_3$   
292 nanorods. While the dielectric constant of the 4 vol% oriented sample is still keep  
293 high to 15.6. The abruptly decrease in the dielectric loss of the percolative composite  
294 in the low frequency range could be attributed to the rearrangement of  $\text{Bi}_2\text{S}_3$  nanorods  
295 along the tensile-strain direction in the  $\text{Bi}_2\text{S}_3/\text{PVDF}$  nanocomposites. In the

296 hot-stretching process, the nanocomposite materials have the effect of “self-repairing”  
297 when the matrix material (PVDF) is at its viscoelastic temperature. This study  
298 provides a useful but simple method to reducing the dielectric loss of the composites  
299 materials which are constituted by thermoplastic polymer matrix and fillers with large  
300 aspect ratio.
