This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. This Accepted Manuscript will be replaced by the edited, formatted and paginated article as soon as this is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Diorganotin(IV) 4,6-dimethyl-2-pyrimidyl selenolates: Synthesis, structures and their utility as molecular precursors for the preparation of SnSe$_2$ nano-sheets and thin films

The complexes of composition, [R$_2$Sn{SeC$_4$H(Me-4,6)$_2$N$_2$}]$_2$ (R = Me, Et, $^n$Bu or $^t$Bu) have been isolated by the reaction of R$_2$SnCl$_2$ with NaSeC$_4$H(Me-4,6)$_2$N$_2$. The treatment of [R$_2$Sn{SeC$_4$H(Me-4,6)$_2$N$_2$}]$_2$ with R$_2$SnCl$_2$ afforded chloro complexes, [R$_2$SnCl{SeC$_4$H(Me-4,6)$_2$N$_2$}] (R = Me, $^n$Bu or $^t$Bu). These complexes were characterized by elemental analyses, and NMR ($^1$H, $^{13}$C, $^{77}$Se, $^{119}$Sn) spectroscopy. The molecular structures of [K$_2$Sn{SeC$_4$H(Me-4,6)$_2$N$_2$}] and [K$_2$SnCl{SeC$_4$H(Me-4,6)$_2$N$_2$}] were established by single crystal X-ray diffraction analyses. Thermolysis of [R$_2$Sn{SeC$_4$H(Me-4,6)$_2$N$_2$}] (R = Et, $^n$Bu or $^t$Bu) in oleylamine (OLA) afforded nanocrystalline hexagonal phase of SnSe$_2$. Thin films of SnSe$_2$ were deposited on silicon wafers by AACVD of [K$_2$Sn{SeC$_4$H(Me-4,6)$_2$N$_2$}]. The nanostructures and thin films were characterized by solid state diffuse reflectance spectroscopy, XRD, EDX, SEM and TEM techniques. The solid state diffuse reflectance measurements of the nanosheets showed direct and indirect band gaps in the ranges of 1.76 – 2.30 eV and 1.38 – 1.49 eV, respectively which are blue shifted relative to bulk tin selenide.

**Keywords:** Diorganotin complexes, 2-Pyrimidylselenolate, Tin selenide, nanostructures, Thin films, NMR, X-ray structure

**Introduction**

Interest in tin chalcogenide semiconductor materials is growing rapidly due to their desirable electronic and optical properties which make them promising candidates for photovoltaic devices$^{1-5}$. They are also emerging as alternatives to other chalcogenide materials like PbE, CdE, CuInE$_2$ (E = S, Se, Te), etc; due to their higher carrier mobility, lower toxicity as well as lower cost$^6$$^7$. 

Page 1 of 27
Among tin chalcogenides, tin selenides have received considerable attention in recent years. Tin selenides exist in two stoichiometric narrow direct band phases, i.e. orthorhombic SnSe (band gap \( \sim 1.0 \) eV) and hexagonal SnSe\(_2\) (band gap \( \sim 0.9 \) eV) and adopt layered structures at room temperature\(^5,8\). Anisotropic properties of the SnSe have been exploited for thermoelectric and photovoltaic applications\(^8,9\), whereas the composites of two dimensional layered SnSe\(_2\) with graphene have been used as an anode material for lithium ion batteries\(^5\).

Several synthetic approaches have been adopted for the preparation of tin selenide nano-structures and for deposition of thin films. Usually SnCl\(_2\) and suitable selenium source (e.g., R\(_2\)Se, TOP-Se, etc.) are employed to prepare SnSe\(^{10,11}\) and SnSe\(_2\) \(^5,10,12\). Single source molecular precursor (ssp) strategy is a versatile material growth process. It has been successfully employed for the preparation of variety of nanomaterials and also for the deposition of thin films. This route has met with a little success in the case of tin selenide possibly due to limited exploration of tin complexes with selenium ligands as ssp. Boudjouk and co-workers used benzyltin [e.g., (Bz\(_2\)SnE)\(_3\), (Bz\(_3\)Sn)\(_2\)E]\(^13\) and phenyl tin [e.g., (Ph\(_3\)Sn)\(_2\)E, where E = S, Se, Te]\(^14,15\) chalcogenides for the synthesis of tin chalcogenides, but the resulting materials were often contaminated with elemental tin\(^15\). The complex [Sn(CH(SiMe\(_3\))\(_2\)]\(_2\)(µ-Se)]\(_2\) has been employed for deposition of thin films of SnSe by MOCVD\(^16\), whereas [Sn(SeC\(_5\)H\(_4\)N)\(_4\)]\(_2\) could not be used for deposition of thin films due to low volatility of the complex, although it yielded SnSe on thermolysis\(^17\). The ssp for SnSe\(_2\) are rather rare. The bulk thermolysis of [Sn(SeC\(_5\)H\(_4\)N)\(_4\)] yields SnSe\(_2\) \(^17\). Recently we have reported diorganotin 2-pyridylselenolate complexes which on thermolysis in coordinating solvents afforded SnSe and SnSe\(_2\) depending on the pyrolysis condition\(^18\) whereas the complex, [\(^1\)Bu\(_2\)Sn(SeC\(_5\)H\(_4\)N)\(_2\)] could deposit thin films of only SnSe\(_2\) \(^18\). The higher deposition temperature of these complexes has led to vaporization of selenium giving SnSe and in some cases a mixture of SnSe and SnSe\(_2\). The lower deposition temperature precursors are likely to afford SnSe\(_2\) which could be accomplished with the 2-pyrimidyl selenolates of diorganotin(IV).

Herein we describe the synthesis of a new series of diorganotin precursors derived from 4,6-dimethyl-2-pyrimidyl selenolate which served the dual purpose of synthesis of SnSe\(_2\) nanosheets as well as precursors for deposition of SnSe\(_2\) thin films.

**Experimental**

**Materials and Methods**

Diorganotin chlorides (R\(_2\)SnCl\(_2\); R = Me, Et, \(^1\)Bu or \(^2\)Bu), oleylamine (OLA) and analytical grade solvents were obtained from commercial sources. The diselenide, [SeC\(_4\)H(Me-4,6)\(_2\)N\(_2\)]\(_2\) \(^{1\text{H}}\) NMR
(CDCl$_3$) $\delta$: 2.37 (s, Me); 6.71 (s, CH-5). $^{13}$C{$_1^1$H} NMR (CDCl$_3$) $\delta$: 23.7 (Me); 117.2 (CH-5); 165.7 (C-2); 167.5 (C-4,6). $^{77}$Se{$_1^1$H} NMR (CDCl$_3$) $\delta$: 486 ppm was prepared according to literature method.$^{19}$

Elemental analyses were carried out on a Thermo Fischer Flash EA-1112 CHNS analyzer. The $^1$H, $^{13}$C{$_1^1$H}, $^{77}$Se{$_1^1$H} and $^{119}$Sn{$_1^1$H} NMR spectra were recorded on a Bruker Avance-II NMR spectrometer operating at 300, 75.47, 57.24 and 111.92 MHz, respectively. Chemical shifts are relative to internal chloroform peak for $^1$H and $^{13}$C{$_1^1$H} NMR spectra, external Ph$_2$Se$_2$ ($\delta$ 463 ppm relative to Me$_2$Se) in CDCl$_3$ for $^{77}$Se{$_1^1$H} and 30% Me$_4$Sn in C$_6$D$_6$ for $^{119}$Sn{$_1^1$H} NMR spectra. Optical diffuse reflectance measurements in the range 200−1800 nm (0.68 eV to 6.2 eV) were performed on a JASCO V-670 two-beam spectrometer with a diffuse reflectance (DR) attachment consisting of an integration sphere coated with barium sulfate which was used as a reference material. Measured reflectance data were converted to absorption (A) using Kubelka-Munk remission function.$^{20}$ The band gaps of the samples were estimated by extrapolating the linear portion of the plot to X (energy) axis.

Thermogravimetric analyses (TGA) were carried out on a Nitzsch STA 409 PC-Luxx TG-DTA instrument, which was calibrated with CaC$_2$O$_4$.H$_2$O. The TG curves were recorded at a heating rate of $10$ °C min$^{-1}$ under a flow of argon. X-ray powder diffraction patterns were obtained on a Philips PW-1820 diffractometer using CuK$_a$ radiation. SEM and EDX measurements were carried out on ULTRA 55 FESEM of Zeiss and Oxford Inca instruments, respectively. Tecnai G2 T20 transmission electron microscopes operating at accelerating voltages up to 200 kV were used for TEM studies. The samples for TEM and SAED were prepared by placing a drop of sample dispersed in acetone/toluene on a carbon coated copper grid.

Intensity data for $[^n$Bu$_2$Sn{SeC$_4$H(Me-4,6)$_2$N$_2$}]$_2$ (3) $[^n$Bu$_2$Sn{SeC$_4$H(Me-4,6)$_2$N$_2$}]$_2$ (4) and $[^t$Bu$_2$Sn{SeC$_4$H(Me-4,6)$_2$N$_2$}Cl] (7) were collected at room temperature (298 ± 2K) on a Rigaku AFC7S diffractometer using graphite monochromated Mo K$_a$ ($\lambda$ = 0.71069 Å) radiation so that $\theta_{\text{max}}$ = 27.5°. The unit cell parameters (Table 1) were determined from 25 reflections measured by a random search routine. The intensity data were corrected for Lorentz, polarization and absorption effects with an empirical procedure.$^{21}$ The structures were solved by direct methods using SHELX-97$^{22}$ and refined by full-matrix least squares methods. The non-hydrogen atoms were refined anisotropically. The hydrogen atoms were fixed in their calculated positions. Molecular structures were drawn using ORTEP.$^{23}$
Syntheses of complexes

\[ \text{[Me}_2\text{Sn[SeC}_4\text{H(Me-4,6)N}_2\text{]}}_2 \] (1)

To a freshly prepared solution of NaSeC\(_4\)H(Me-4,6)\(_2\)N\(_2\) [obtained by the reduction of \{SeC\(_4\)H(Me-4,6)\(_2\)N\(_2\)}\(_2\) (191 mg, 0.51 mmol) in toluene with methanolic NaBH\(_4\) (39 mg, 1.30 mmol)], solid Me\(_2\)SnCl (112 mg, 0.51 mmol) was added with vigorous stirring which continued for 3 h at room temperature. The solvents were evaporated under vacuum and the residue was washed thoroughly with toluene-hexane mixture (1:20 v/v). The pure product was extracted with chloroform and filtered to remove NaCl. The filtrate was dried under reduced pressure and recrystallized from toluene-dichloromethane mixture to give a white powder (yield: 160 mg, 60%), mp 163 °C. Anal. Calcd. for C\(_{14}\)H\(_{20}\)N\(_4\)Se\(_2\)Sn: C, 32.28; H, 3.87; N 10.75%. Found: C, 36.67; H, 5.41; N, 6.05%. ¹H NMR (CDCl₃) δ: 0.89 (t, SnCH₂CH₂CH₂CH₃, 6 H, 7.2 Hz); 1.37 (m), 1.69-1.77 (m) (SnBu); 2.35 (s, C₄H(Me-4,6)N₂, 6 H); 6.84 (s, CH-5, C₄H(Me-4,6)N₂). ¹³C{¹H} NMR (CDCl₃) δ: 13.6 (SnCH₂CH₂CH₂CH₃), 24.6 (SnCH₂CH₂CH₂CH₃, 1J(¹¹⁹Sn−¹³C) = 486 Hz; 1J(¹¹⁷Sn−¹³C) = 465 Hz), 23.2 (C₄H(Me-4,6)N₂), 26.2 (SnCH₂CH₂CH₂CH₃, 2J(¹¹⁹Sn−¹³C) = 90 Hz), 27.8 (SnCH₂CH₂CH₂CH₃, 3J(¹¹⁹Sn−¹³C) = 35 Hz), 116.7 (C-5), 167.2 (C-4,6), 170.7 (C-Se). ⁷⁷Se{¹H} NMR (CDCl₃) δ: 228 (1J(¹¹⁹Sn−²⁷Se) = 748 Hz; 1J(¹¹⁷Sn−²⁷Se) = 713 Hz). ¹¹⁹Sn{¹H} NMR (CDCl₃) δ: −74 (1J(¹¹⁹Sn−²⁷Se) = 755 Hz) ppm.
Prepared in a similar fashion to 5 and recrystallized from dichloromethane-hexane as colorless crystals in 82% yield, mp 101 °C. Anal. Calcd. for C_{14}H_{25}N_{2}ClSeSn: C, 36.99; H, 5.54; N, 6.16%. Found: C, 36.81; H, 5.51; N, 5.98%.

$^1$H NMR (CDCl$_3$) $\delta$: 1.48 (s, $^t$Bu$_2$Sn, 18 H, $^3$$J$(119Sn-$^1$H) = 110 Hz; $^3$$J$(117Sn-$^1$H) = 108 Hz); 2.38 (s, C$_4$H(Me-4,6)N$_2$, 6 H); 6.81 (s, C$_5$H-5, C$_4$H(Me-4,6)N$_2$).

$^{13}$C{$^1$H} NMR (CDCl$_3$) $\delta$: 23.9 (C$_4$H(Me-4,6)N$_2$), 30.9 (Me$_3$C-Sn), 43.4 (C-Sn, $^1$$J$(119Sn-$^{13}$C) = 398 Hz, $^1$$J$(117Sn-$^{13}$C) = 380 Hz), 117.0 (C-5), 167.0 (C-4,6), 171.5 (C-Se).

$^{77}$Se{$^1$H} NMR (CDCl$_3$) $\delta$: 197 ($^1$$J$(119Sn-$^{77}$Se) = 910 Hz; $^1$$J$(117Sn-$^{77}$Se) = 870 Hz). $^{119}$Sn{$^1$H} NMR (CDCl$_3$) $\delta$: $-20$ ($^1$$J$(Sn-Se) = 912 Hz) ppm.

**Preparation of tin selenide nanoparticles**

In a typical experiment, an OLA (2 ml) dispersion of complex 2 (100 mg, 0.18 mmol), 3 (100 mg, 0.17 mmol) or 4 (100 mg, 0.17 mmol) was injected rapidly into a preheated (210 °C) OLA (8 ml) in a three-necked flask with vigorous stirring under flowing argon. The temperature of the reaction mixture was dropped in the range of ~185 °C upon injection which again raised to 210 °C. The reaction mixture was kept at 210 °C for different durations (2, 5 and 10 minutes). After the desired growth time, the reaction mixture was cooled down rapidly to 95-98 °C and quenched by injecting toluene (4 ml). The resulting nanocrystals were separated by precipitating with excess methanol followed by centrifugation to give a black powder.

**Preparation of thin films by Aerosol Assisted Chemical Vapor Deposition (AACVD)**

A toluene solution (25 ml) of 4 (125 mg, 0.21 mmol) was used to generate aerosol by an ultrasonic humidifier. The aerosol was transported over a period of 1 h using argon as a carrier gas (flow rates of 180 sccm) to a preheated silicon wafer (110) orientation placed in a turbo furnace at 375 °C.

**Results and discussion**

**Synthesis and Spectroscopy**

Treatment of R$_2$SnCl$_2$ (R = Me, Et, $^t$Bu, $^1$Bu) with two equivalents of sodium 4,6-dimethyl-2-pyrimidyl selenolate, NaSeC$_4$H(Me-4,6)$_2$N$_2$, in a toluene-methanol mixture gave diorganotin selenolate complexes, [R$_2$Sn{SeC$_4$H(Me-4,6)$_2$N$_2$}] (R = Me (1), Et (2), $^t$Bu (3), $^1$Bu (4)) (Scheme 1). The latter when treated with an equivalent of R$_2$SnCl$_2$ in toluene mixture gave chloro complexes, [R$_2$SnCl{SeC$_4$H(Me-4,6)$_2$N$_2$}] (R = Me (5), $^t$Bu (6), $^1$Bu (7)).
Scheme 1. Synthesis of organotin selenolate complexes

The $^1$H, $^{13}$C,$^1$H, $^{77}$Se,$^1$H and $^{119}$Sn,$^1$H NMR spectra were recorded in CDCl$_3$ (Supplementary information). $^1$H and $^{13}$C NMR spectra showed expected resonances and peak multiplicities. The pyrimidyl ring proton resonances shifted to down field with reference to the corresponding signals for the diselenides. The magnitudes of $^1$J($^{119}$Sn–$^{13}$C) and $^2$J($^{119}$Sn–$^1$H) for dimethyltin complexes (1 and 5) are similar to other dimethyltin(IV) derivatives with thio-/seleno-pyridine ligands.$^{18,24}$ $^1$J(Sn-C) values decreases gradually on replacing methyl groups attached to tin by Et, $^t$Bu or $^n$Bu which may be due to the increasing steric hindrance resulting in diminishing the electron acceptor property of tin.$^{18,25}$ This effect is further corroborated by larger Sn-C bond length in $[^t$Bu$_2$Sn(2-SeC$_5$H$_4$N)$_2]$ as compared to its methyl analogue$^{18}$. The $^{77}$Se,$^1$H NMR spectra displayed single resonances (range 170-262 ppm) which were flanked by $^{119}$Sn and $^{117}$Sn satellites with the coupling constants in the range 723-977 Hz. The magnitude of $^1$J($^{119}$Sn–$^{77}$Se) coupling constant is higher than the analogous complexes derived 2-pyridine selenolate ligand, $[^R'_2$Sn(SeC$_5$H$_3$R-3)$_2]$ (R = H or Me) and $[^R'_2$SnCl(SeC$_5$H$_3$(R-3))].$^{18}$ This indicates stronger Sn-Se bonding in these complexes than the 2-pyridine selenolate derivatives which is reflected from the Sn-Se bond distances determined from X-ray analysis (see later). The resonance within the series (bis or chloro) is shielded on replacing methyl groups on tin by Et, $^t$Bu or $^n$Bu groups which could be due to +I effect of the larger alkyl group. Similarly, $^{77}$Se signal of 4 is shielded relative to that of 3 as +I effect is more pronounced in branched chain alkyl groups compared to the straight chain alkyl groups with same number of carbons. The $^{77}$Se resonance for chloro derivatives (5-7) are deshielded (~30-20 ppm) with respect to the corresponding bis complexes.

In contrast to $^1$J(Sn-C), $^1$J(Sn-Se) values gradually increase with increasing carbon chain length of the alkyl group which may be due to increased inductive effect (+I ). The +I effect increases the electron density on tin atom results in better overlapping of tin and selenium molecular orbitals. Among $[^t$Bu$_2$Sn{SeC$_4$H(Me-4,6)$_2$N$_2$}]$ (3) and its $^t$Bu- analogue (4), the latter has higher $^1$J(Sn-Se) value.
compared to the former. This is due to relatively stronger +I effect in case of branched chain alkyl groups than straighter one with the same number of carbon atoms. Corresponding chloro derivatives show smaller coupling constant of (Sn-Se) than the bis complexes. This may be due to –I effect of Cl attached to Sn which reduces the electron density on tin leading to decreased orbital overlap between tin and selenium.

The $^{119}$Sn{¹H} NMR spectra showed single resonances in the range –135 to 28 ppm with $^1J$(¹¹⁹Sn–⁷⁷Se) couplings varying between 724 and 999 Hz. These resonances are deshielded with reference to the $^{119}$Sn NMR signal for the corresponding 2-pyridylselenolate complexes indicating weaker Sn...N interactions in the former. The resonance within the series (bis or chloro) is deshielded on replacing methyl groups on tin by Et, 'Bu or 'Bu groups which could be due to +I effect of the larger alkyl group, and is in conformity with the trend noted for diorgaotin dichlorides (e.g., R₂SnCl₂; R/δ¹¹⁹Sn (in ppm) = Me/141; Et/126, 'Bu/122; 'Bu/52).²⁶ The variable temperature $^{119}$Sn NMR spectra of 7 were recorded in methanol-d₄ to assess whether there is any interaction between tin and nitrogen. There was a slight shift in the $^{119}$Sn NMR resonance on lowering the temperature from RT to -40°C ($^{119}$Sn NMR δ: -18 at RT and -22 ppm at -40°C) (Supplementary information) indicating that there is no change in the coordination around tin. Temperature dependent $^{119}$Sn NMR chemical shifts of diorganotin carboxylates have been attributed to change in the coordination environment around tin.²⁷

**X-ray Crystallography**

The molecular structures of [³Bu₂Sn{SeC₄H(Me-4,6)₂N₂}₂] (4) and [³Bu₂Sn{SeC₄H(Me-4,6)₂N₂}Cl] (7) with atomic numbering scheme are shown in Figures 1 and 2. Selected inter-atomic parameters are given in Tables 2 and 3. Both the complexes are discrete monomers, but differ in the coordination geometry around tin.

The coordination geometry around tin in [³Bu₂Sn{SeC₄H(Me-4,6)₂N₂}₂] (4) can be defined by carbon atoms of two 'Bu groups and selenium from monodentate 2-pyridylselenolate ligands. The Sn...N distances are longer than the sum of their covalent radii (2.15 Å) but are shorter than the sum of van der Waal’s radii (3.72 Å). The Sn...N separation in the present case is longer than the one reported in [³Bu₂Sn(SeC₅H₄N)₂] (Sn...N = 2.425(9) Å).²⁸ A similar structure is observed for [³Bu₂Sn{SeC₄H(Me-4,6)₂N₂}₂] (3) but due to high R factor, the structure and data are included in supplementary information (Figure S1, Tables S1 and S2). The Sn–Se bond distance (2.5800(6) Å) is shorter than those reported in [Sn(SeC₅H₄N)₂] (2.681, 2.759 Å)²⁷, [³Sn(SePh)₂] (2.668, 2.675, 2.683, 2.673 Å)²⁸ and [³Bu₂Sn(2-SeC₅H₄N)₂] (2.622(2) Å). The Se–Sn–Se angle (86.19(3)°) is contracted by 3° to that of [³Bu₂Sn(2-
The Sn–Butyl bond distance (2.205(4) Å) is slightly shorter than that of \([\text{tBu}_2\text{Sn}(2-\text{SeC}_5\text{H}_4\text{N}))_2]\) (2.246(10) Å) while it is comparable to the value reported for \([\text{tBu}_2\text{Sn(µ-OH)}\{\text{O(S)P(OEt)}_2\}])_2\) (av. 2.16 Å).

The tin in \([\text{tBu}_2\text{SnCl}\{\text{SeC}_4\text{H}(\text{Me-4,6})_2\text{N})\}]\) (7) acquires a distorted trigonal bipyramidal geometry defined by a Cl, two 'tBu and Se, N of a selenopyrimidine ligand where the chloride atom and chelating pyrimidylselenolate occupy the equatorial plane while two tert-buty1 groups are directed axially. The Sn...N distance (2.784 Å) is shorter than the sum of their van der Waals radii

Thermal studies
Thermo gravimetric analyses (TGA) (Supplementary information Figures S2 - S6) of these complexes were performed under a flowing argon atmosphere. The bis complexes, \([\text{R}_2\text{Sn}\{\text{SeC}_4\text{H}(\text{Me-4,6})_2\text{N})\}_2]\) underwent a single step decomposition. From the weight loss in the TG pattern it can be inferred that the complexes \([\text{Me}_2\text{Sn}\{\text{SeC}_4\text{H}(\text{Me-4,6})_2\text{N})\}_2]\) (weight loss: found 62.0%, calcd. 58.8%) and \([\text{tBu}_2\text{Sn}\{\text{SeC}_4\text{H}(\text{Me-4,6})_2\text{N})\}_2]\) (weight loss: found 68.0%, calcd. 67.3%) gave SnSe whereas \([\text{Et}_2\text{Sn}\{\text{SeC}_4\text{H}(\text{Me-4,6})_2\text{N})\}_2]\) (weight loss: found 54.8%, calcd. 49.6%) and \([\text{tBu}_2\text{Sn}\{\text{SeC}_4\text{H}(\text{Me-4,6})_2\text{N})\}_2]\) (weight loss: found 54.5%, calcd. 54.3%) afforded SnSe₂. The %weight loss of 2 is higher than expected for the formation of SnSe₂ which may be due to partial sublimation during major weight loss step prior to the formation of SnSe₂. REVIEW The complex, \([\text{tBu}_2\text{Sn}\{\text{SeC}_4\text{H}(\text{Me-4,6})_2\text{N})\}_2\text{Cl}\]) (7) underwent decomposition via two overlapping steps leading to the formation of tin (weight loss: found 71.2%, calcd. 73.8%). The first step corresponds to the formation of SnSe₂ (weight loss: found 64%, calcd. 69.6%) which further decomposes to tin metal finally.

Preparation and characterization of tin selenide nanostructures
Tin selenides nanostructures were prepared by employing 2, 3 and 4 (the chloro complexes have not been used due to their tendency to either volatilize completely or decompose to tin metal (TG analysis), while \([\text{tBu}_2\text{Sn}\{\text{SeC}_4\text{H}(\text{Me-4,6})_2\text{N})\}_2]\) (4) was used for deposition of thin films by AACVD. The resulting products were characterized by solid state diffuse reflectance, thermo gravimetric analysis,
powder X-ray powder diffraction (PXRD), energy dispersive X-ray analysis (EDX), SEM, TEM and selective area electron diffraction (SAED) techniques.

**Preparation of tin selenide nano-sheets**

Tin selenide nanosheets were synthesized by hot injection of \([R_2Sn\{SeC_4H(Me-4,6)_{2}N_2\}]_2\) \([R = Et (2), 'Bu (3) or 'Bu (4)]\) in oleylamine (OLA). Selection of high boiling long chain alkylamine as a surfactant is based on three factors: (i) high boiling point of the amine ensures that the temperature can be raised sufficiently high for decomposition of the single source precursor, (ii) affinity of amines to coordinate with tin and (iii) long chain prevents growth and agglomeration of the nanostructures due to steric hindrance. In a typical experiment, a pale yellow solution of the complex in OLA is injected into hot OLA which quickly changed to different colors ranging from yellow to red to black. After the desired growth time, the reaction was cooled rapidly and toluene (4 ml) was added. The pure black powder was obtained by addition of methanol followed by centrifugation.

**Characterization of tin selenide nanostructures**

Thermolysis experiments of 2, 3 and 4 (100 mg each) in OLA (10 ml) for 2, 5 and 10 minutes, respectively at 210 °C gave black residue of tin selenides. The XRD profiles (Figure 3) of the residues obtained by thermolysis for 2 minutes of 2 and 4 showed a set of reflections originating from (009), (104), (109), (1018), (0027), (0028), (111), (119), (1113), (0033), (209) (for thermolysis of 2); (009), (109), (1018), (111), (119), (1113), (209) (for thermolysis of 4) planes of hexagonal phase of SnSe\(_2\) (JCPDS File No. 40-1465) corroborated by elemental composition analysis by EDX [from 2: Sn:Se atom ratio is 31.6:68.4 or 1:2.2 and from 4: Sn:Se atom ratio is 30.9: 69.1 or 1:2.2]. Similar pattern [Bragg reflections (009), (101), (108), (109), (1018), (1019), (0027), (1022), (110), (119), (209)] was observed for a product obtained from thermolysis of 3 and was assigned for hexagonal SnSe\(_2\). However, the XRD pattern displayed an additional peak at 2\(\theta\) = 23.5° which may be assigned to selenium impurity. The intensity of these Bragg reflections indicates their crystalline nature. The intensity of reflection from (009) plane indicates that structures has a preferential orientation in [001] direction. Such type of highly oriented 2D nanostructures is previously reported\(^ {16}\) Similar Bragg’s reflections with different lattice parameters (Supplementary information, Table S3) were noted for the residues obtained from 2-4 by thermolysis carried out for 5 and 10 minutes (Supplementary information, Figures S7 and S8).

SEM images (Figure 4, S9) of these residues revealed sheet like structures having smooth and rough edges. The residues obtained by thermolysis of 2 displayed sheets which are uniformly distributed and have rough edges (Figure 4a). The magnified image in the inset showed that the sheets have thickness
in the range of 10-20 nm. SEM micrographs of the residues afforded by thermolysis of 3 revealed sharp edged sheets.

Transmission electron microscopy has been used to find the morphology and phase of the residues. TEM image of the residue obtained by thermolysis of 2 showed needle like structures (Figure 5) which are rolled forms of the sheets. The rolling of sheets happens due to the use of solvent during the preparation of TEM samples because of surface tension. The corresponding SAED pattern exhibit set of lattice planes, (0010), (1021) and (1031) related to hexagonal phase of SnSe₂ (JCPDS File No. 40-1465). The spot like pattern indicate single crystalline nature of the rolled sheets. TEM image of the residue obtained by thermolysis of 4 revealed sheets like structures having the boundaries in sub micron range (other than thickness of sheets) and sharp needle like structures which are formed due to the rolling of the nano-sheets (Inset of Figure 6a). Individual nanosheets were also observed in addition to the rolled sheets. HRTEM image of the sheets showed lattice plane with interplanar distance of 6.20 Å corresponding to (009) plane of hexagonal phase of SnSe₂ (JCPDS File No. 40-1465) (Figure 6b).

**Preparation and characterization of tin selenide thin films**

One of the complexes, [tBu₂Sn{SeC₄H(Me-4,6)₂N₂}]₂ (4) was employed for deposition of SnSe₂ thin film as tBu is a good leaving group. Black tin selenide thin films were deposited on p-type silicon (110) substrate using toluene solution of 4 at 375 °C for 1 h. There was no deposition below 375 °C while very poor coverage at 400 °C and above. XRD pattern of as prepared thin films (Figure S10) deposited at 375 °C for 1 h showed peaks at 2θ = 25.8, 30.7, 33.9, 37.9, 41.2, 43.4, 47.7, 49.7, 51.8, 54.3 and 57.8° which may be assigned to the reflections from (0016), (109), (0021), (1016), (1019), (1021), (111), (1025), (1112), (1115) and (209) planes of hexagonal phase of SnSe₂ (JCPDS File No. 40-1465). This film annealed at 375 °C for 1 h showed XRD reflections (Figure 7) from (009), (100), (109), (0021), (1016), (1021), (110), (1112), (0033) and (2010) planes of hexagonal SnSe₂ (JCPDS File No. 40-1465). The composition is further confirmed by EDX analysis (for as prepared thin film: Sn:Se atom ratio is 36.9:63.1 or 1:1.7; for annealed prepared thin film: Sn:Se atom ratio is 38.4:61.6 or 1:1.6). The lattice parameters for as prepared and annealed thin films are a = 3.811(0), c = 55.36(36) Å (as prepared thin films) and a = 3.811(0), c = 55.05(3) Å (annealed thin films), respectively which are in accord with the hexagonal SnSe₂ (JCPDS-40-1465). SEM micrographs (Figure 8) of as prepared thin films revealed irregular morphology. However, the annealed thin films revealed hierarchical flower like structures with an average size of ~15 µm.
Optical properties of SnSe$_2$ nanostructures and thin films

Optical properties of SnSe$_2$ nanostructures were investigated using solid state diffuse reflectance spectroscopy. Kubelka-Munk transformations were performed on solid state diffuse reflectance data to determine the optical direct and indirect band gaps. The band gap values were obtained by extrapolating the absorption onsets to the intersection point of the baseline. The plots of \( [F(R)h\nu]^2 \) versus \( h\nu \) and \( [F(R)h\nu]^{1/2} \) versus \( h\nu \) were used to obtain direct and indirect band gaps, respectively.

The direct and indirect band gaps of the nanosheets obtained by thermolysis of 2 and 4 in OLA at 210 °C for 2, 5 and 10 minutes showed a gradual decrease from 2.22 to 1.82 (direct band gaps) (Supplementary Figure S11), 1.49 to 1.38 eV (indirect band gaps) (for nanosheets obtained from 2) (Supplementary Figure S12) and 2.30 to 1.76 (direct band gaps) (Figure 9), 1.48 to 1.46 eV (indirect band gaps) (for nanosheets obtained from 4) (Supplementary Figure S13) with the increase in reaction time. A blue shift in band gaps was observed for the nanosheets with respect to bulk SnSe$_2$ \([E_g (direct) = 1.62 \text{ eV and } E_g (indirect) = 0.97 \text{ eV}]^{37}\). The gradual increase in the band gap values with decreasing thickness of sheets may be either due to quantum confinement or surface effect of the carriers or lattice distortions or surface lattice defects$^{38}$. Since the thickness of the sheets obtained by thermolysis of 2 and 4 in OLA for 2 minutes are in the range of 10-20 nm and there is systematic increase of band gap with decreasing thickness of sheets, quantum confinement may not be ruled out. Band gap values of 1.67-1.62 eV with crystallite size of 31.2-111.4 nm were reported for thin films of SnSe$_2$ deposited at substrate temperatures of 150-300 °C.$^{39}$ The former values when compared with the direct band gap values of 2.22 and 2.30 eV obtained for SnSe$_2$-nanosheets in the present investigation indicate that these measured values are justified for the sheets of thickness varying between 10-20 nm. However, the direct band gap values between 2.10 to 1.62 were reported as direct allowed transitions while indirect band gap energies in the range of 0.99-1.3 eV for bulk SnSe$_2$.$^{37,40-42}$ The direct$^{40,42}$ and indirect band gap$^{41}$ values estimated in the present investigation are in the range of reported values.

Similarly, the direct and indirect band gap values for as-deposited SnSe$_2$ thin films obtained by AACVD of [\( \text{[Bu}_2\text{Sn\{SeC}_4\text{H(Me-4,6)N}_2\}_2} \)] (4) on silicon substrate at 375 °C for 1 h and annealed thin films are 2.12 and 2.06 eV (direct band gap) (Figure 10) and 1.54 and 1.50 eV (indirect band gap) (Supplementary Figure S14), respectively. The obtained direct and indirect band gap values for SnSe$_2$ thin films are comparable to that of literature values$^{42,43}$. The band gap values correspond to direct and indirect allowed transitions. The decrease in the band gaps for annealed thin films compared to as-deposited thin films may be accounted for thermal expansion of the lattice and temperature dependent electron-phonon interactions$^{39}$. Similar trend in band gap values has been observed for the annealed thin
films with respect to readily deposited thin films in the literature.\(^{42,43}\) Although the deposition and annealed temperatures are same, the total residence time in the furnace is different. As-deposited thin films are placed in furnace for 1 h during deposition while annealed thin films are obtained after heating the as-deposited thin films at 375°C for additional one hour after their deposition. Table 4 gives a comparison of the band gap values reported in the present investigation with the literature values.\(^{42-44}\)

**Conclusion**

Diorganotin(IV) pyrimidyl selenolates complexes have been conveniently synthesized and isolated as air stable monomeric complexes. The complexes, [\(\text{R}_2\text{Sn}\{\text{SeC}_4\text{H(Me-4,6)}_2\text{N}_2\}_2\)] (R = Et, \(^6\)Bu or \(^t\)Bu) were used as single source molecular precursors for the preparation of phase pure SnSe\(_2\) nano-sheets while thin films were deposited using [\('\text{Bu}_2\text{Sn}\{\text{SeC}_4\text{H(Me-4,6)}_2\text{N}_2\}_2\)] by AACVD. The thickness of the nano-sheets are in the range of 10-20 nm. The band gap of nano-sheets varies from 1.7 to 2.3 eV (direct band gaps) and 1.49 to 1.36 eV (indirect band gaps) while the direct and indirect band gaps of thin films are in the range of 2.06-2.12 and 1.50-1.54 eV, respectively. These band gaps are blue shifted relative to bulk SnSe\(_2\) and gradually increases with decrease in the thickness.

**Acknowledgements**

We thank Dr. B. N. Jagatap for encouragement of this work. We are grateful to Head, Analytical Chemistry Division and (Mrs.) N. Raje for providing thermo gravimetric analyses data.

Fig. 8 SEM images of a) as prepared SnSe$_2$ thins films obtained by AACVD of [tBu$_2$Sn{SeC$_4$H(Me-4,6)N$_2$$_2$}] (4) on silicon substrate at 375 °C for 1 h and b) annealed thin film of as prepared thin film at 375 °C for 1 h.
Fig. 9 Plots of \([F(R)h\nu]^2\) vs energy generated by Kubelka-Munk transformation of solid-state diffuse reflectance data of SnSe\(_2\) nano-sheets obtained by thermolysis of \([tBu_2Sn\{SeC_4H(Me-4,6)_{2}N_2\}]\) (4) in OLA at 210 °C for a) 2, b) 5 and c) 10 minutes, respectively for determining direct band gap energies.

Fig. 10 Plots of \([F(R)h\nu]^2\) vs energy generated by Kubelka-Munk transformation of solid-state diffuse reflectance data of a) as-deposited SnSe\(_2\) thin films obtained by AACVD of \([tBu_2Sn\{SeC_4H(Me-4,6)_{2}N_2\}]\) (4) on silicon substrate at 375 °C for 1 h and b) annealed thin films to determine direct band gap energies.
Diorganotin(IV) 4,6-dimethyl-2-pyrimidyl selenolates: Synthesis, structures and their utility as molecular precursors for the preparation of SnSe$_2$ nanosheets and thin films

Adish Tyagi, G. Kedarnath, Amey Wadawale, Alpa Y Shah, Vimal K. Jain and B. Vishwanadh

Organotin complexes, [R$_2$Sn\{SeC$_4$H(Me-4,6)$_2$N$_2$\}]$_2$ and [R$_2$SnCl\{SeC$_4$H(Me-4,6)$_2$N$_2$\}] (R = alkyl) were prepared and utilized as ssps for the preparation of SnSe$_2$ nanosheets and thin films. Tunability of band gaps has been demonstrated.
