This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the Information for Authors.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal’s standard Terms & Conditions and the Ethical guidelines still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.
Evaluating the Effectiveness of POGIL-PCL Workshops

Sally S. Hunnicutt*, Virginia Commonwealth University Department of Chemistry, 1001 W. Main St., Richmond VA 23284

Abstract

The POGIL-PCL (Process-Oriented Guided Inquiry Learning in the Physical Chemistry Laboratory) project has developed a series of workshops to introduce faculty to POGIL-PCL and to facilitate the development of new experiments. More than 60 faculty members from various institutions have attended these workshops. Workshop participants were surveyed in order to evaluate the effectiveness of the workshop and better understand why faculty choose to adopt POGIL-PCL. Of the participants who completed the survey, 76.8% had used POGIL-PCL experiments. The results of the survey show that personal influence is a major factor in all stages of the adoption process.

Introduction

Workshops are often used as a means of disseminating new teaching methodologies to interested faculty. Some studies on the effectiveness of workshops have focused mainly on the rate of adoption of a particular teaching method (Lewis and Lewis, 2006; Baker et al., 2009; Baker et al., 2014; Burke et al., 2004), while others have focused on the development of a community of instructors dedicated to reform (Sirum et al., 2009; Deignan, 2009; Sirum and Madigan, 2010; Wood and Gentile, 2003; Wood and Handelsman, 2004; Connolly and Millar, 2006; Cox, 2004; Paul and Volk, 2002; Lynd-Balta et al., 2006). Prior studies have addressed
the usefulness of workshops designed to promote implementation of various active learning
techniques, such as Just-in-Time Teaching, Problem-Based Learning, Peer-Led Guided Inquiry,
and POGIL (Baker et al., 2014; Burke et al., 2004; Murray et al., 2011; Sirum and Madigan,
2010; Stains et al., 2015). Studies by Baker et al. (2014) and Stains et al. (2015) have
investigated the impact of workshops designed to introduce faculty to multiple active learning
techniques at three-day workshops. These studies have found that intensive workshops can have
a significant impact on instructors’ use of active learning techniques and that instructors often
had a more student-centered approach to teaching after attending workshops (Baker et al., 2014;
Burke et al., 2004; Gibbs and Coffey, 2004; Henderson, 2008; Murray et al., 2011; Stains et al.,
2015). However, the extent of change is often variable, and some researchers have raised
concerns about whether these changes are sustained long-term (Lewis and Lewis, 2006; Murray
et al., 2011; Stains et al., 2015; Emerson and Mosteller, 2000). An understanding of the process
of reform and the factors that lead to change is crucial in order to promote the implementation of
innovative teaching methods. We begin with a discussion of the POGIL-PCL project and then
explore the factors that influence instructors’ decisions to adopt POGIL-PCL.

POGIL-PCL Workshops

The POGIL-PCL project has developed guided-inquiry experiments for the physical
chemistry laboratory at POGIL-PCL workshops. The project objectives are to design, write,
revise, and test guided-inquiry experiments, to encourage faculty to adopt POGIL-PCL, and to
foster the community of physical chemistry faculty. POGIL-PCL workshops were designed to
accomplish these goals. In addition, much of the work of the project continues after participants
attend the workshops, including additional writing, reviewing, and testing. The workshops are
described in detail in this section, and the structure of POGIL-PCL experiments is described more fully in the next section.

A sample agenda for the two-day workshops is shown in Appendix 1. The workshops open with participants doing a POGIL-PCL experiment. Immersion in a POGIL-PCL experiment allows faculty to get a sense of how the experiments work from students’ perspectives and to observe how the experiments are facilitated. After this experience, participants then discuss the key elements of a POGIL-PCL experiment, the differences between traditional and POGIL experiments, and the facilitation of a POGIL-PCL experiment. Next, workshop participants review previously written experiments using a screening rubric (Appendix 2). The rubric emphasizes the key elements of POGIL-PCL experiments. By using the rubric, faculty better understand the general experiment structure and simultaneously learn about additional experiments.

A key part of the workshops is the opportunity to write a POGIL-PCL experiment. The writing portion of the workshops has been instrumental in expanding the number of POGIL-PCL experiments available, which is one of the goals of the project. Workshop participants work in groups of two to four people on the experiment they have chosen. Participants have revised existing POGIL-PCL experiments, converted standard physical chemistry experiments into POGIL experiments, or used their own ideas for new POGIL-PCL experiments. Up to eight hours over the course of the workshop are dedicated to writing and editing experiments. Instructors continue to work on the experiments after they leave the workshop in a variety of ways, including:

- writing and/or revising their own experiments and instructor’s handbook
• testing the experimental procedure for newly developed experiments at their institution (alpha-testing)
• writing reviews of new experiments written by others
• implementing a fully-developed experiment (exactly as written by others) at their institution, and writing a review (beta-testing)

One criticism of some education research and dissemination methods is that instructors are simply given the materials and told what to do; the instructors have little or no involvement in developing materials. The lack of interaction between researchers and instructors often leads to problems with implementation (Henderson and Dancy, 2008). The writing portion of POGIL-PCL workshops addresses this concern by allowing instructors to focus on developing materials suitable for use in their own laboratories and by fostering collaboration among participants and researchers (facilitators). Development-style workshops have been developed for the POGIL Biochem project (Murray et al., 2011). The collaboration occurs not only between participants and facilitators but also between new participants and experienced participants (those who have previously attended workshops). The planned time for social interaction and networking among participants and facilitators further reinforces the collaboration and network among the new and experienced participants.

At the end of the workshop, participants provide feedback for the workshop facilitators. Participants are asked to fill out a Workshop Assessment form listing strengths of the workshops, the improvements the workshop needs, and any insights they gained from the workshop. The feedback provided by workshop participants is used to improve future workshops.
The workshops described in the previous paragraphs and illustrated in Appendix 1 are two-day workshops. The POGIL-PCL Project also holds half-day workshops at the Biennial Conference on Chemical Education (BCCE). Because the workshops at the BCCE are only a few hours long, the agenda emphasizes experiencing and then discussing a POGIL-PCL experiment. The workshops at BCCE provide instructors with an introduction to POGIL-PCL, but, because the BCCE workshops are so short, participants do not have as much time for the socializing and networking with other physical chemistry faculty that occurs at the two-day workshops. The BCCE workshops also do not include time for writing and development of experiments. Approximately half of the faculty who have attended the BCCE workshops have later attended the two-day workshops.

The workshops were advertised via email, announcements at pogil.org, conference presentations at regional and national American Chemical Society meetings, and at the 2012 Biennial Conference on Chemical Education.

**The POGIL-PCL Experiment Structure**

POGIL-PCL is a student-centered approach that utilizes guided inquiry and collaborative learning (Allen et al., 1986; Deckert et al., 1998; Lord and Orkwiszewski, 2006; Pavelich and Abraham, 1979; Poock et al., 2007; Rudd et al., 2007; Rudd et al., 2001; Schroeder and Greenbowe, 2008; Spencer, 1999; Farrell et al., 1999). The model of the POGIL-PCL learning cycle shown in Figure 1 was developed through the discussion and testing of experiments at the workshops (Hunnicutt et al., 2015). Students work through multiple “data-think cycles” (see Figure 1) in which they answer guiding questions, formulate a hypothesis, run an experiment, and analyze the resulting data. Specific experimental parameters such as concentrations or masses of reagents, volumes of reagents, and the number of trials necessary to obtain enough
data, are determined by the students in small groups or as a whole class. The experiments end with in-depth questions that require students to apply the concepts they have learned. POGIL-PCL experiments rely on data-pooling by the students, so one experiment is often carried out simultaneously by the whole class. A few instructors who attended workshops have reported using POGIL-PCL experiments in a round-robin setting, in which different teams of two to four students carry out different experiments in the same class period.

**Figure 1.** Diagram of the POGIL-PCL cycle. The experiment begins with the title as a question, includes multiple “data-think” cycles, and concludes with a set of post-experiment questions focusing on application. (Reproduced by permission from Hunnicutt et al., 2015)

**Process of Change**

Some of the faculty who attend POGIL-PCL workshops have previously attended workshops and currently use POGIL in their laboratory or lecture courses, while others are new to POGIL. The faculty who attend workshops include:

- those who have heard about POGIL and are interested in learning more,
- those who have begun to use POGIL at their institutions, and
- those who primarily use POGIL at their institutions.
This process of change from traditional laboratory teaching methods to using POGIL goes through several stages. The diffusion of innovations theory developed by Rogers describes the process of implementing change in five stages: knowledge, persuasion, decision, implementation, and confirmation (Rogers, 2003; Sahin, 2006). The first stage, knowledge, involves becoming aware of the innovation and learning how it is used. In the persuasion stage, an instructor begins to form an opinion based on the perceived advantages, disadvantages, and complexities of the innovation, the compatibility with their current environment, and the opinions of their peers. After learning of the innovation and forming an opinion about it, the instructor makes a decision to adopt or reject the innovation. An instructor may initially decide to adopt then later reject the innovation or discontinue use, or initially reject the innovation and later adopt it. Following the decision to adopt, the instructor enters the implementation stage. During the implementation stage, an instructor may seek support from more experienced users of the innovation. The final stage in this process of change is the confirmation stage, in which instructors seek support for their decision to adopt (Rogers, 2003, Sahin, 2006).

Instructors who attend POGIL-PCL workshops may be at any of the five stages in the diffusion of innovations. Instructors who are in the knowledge stage may be dissatisfied with the experiments they currently use and come to the workshops to learn about another way to teach a lab course, while those who are in the persuasion stage have heard about POGIL and want to learn more about it in order to decide whether they want to try POGIL experiments in their laboratory course. Some are in the implementation stage and are looking for support to deal with the challenges they have encountered or for more experiments for their course. More experienced participants may be in the confirmation stage and come to the workshop for the support from like-minded instructors.
After the workshop, instructors continue to move through these stages. Those who choose to implement may try previously developed experiments, or they participate in beta-testing. Beta-testing is the process of testing and reviewing experiments that are under development; once an experiment has been successfully tested, it may be considered ready for distribution to the community. After beta-testing the experiments with their students, instructors provide feedback to the authors of the experiment. This interaction plays an important part in developing experiments for the POGIL-PCL project and in supporting instructors in both the implementation and confirmation stages. Developers provide the experiments to instructors to implement with different groups of students, and instructors provide the developers with feedback on what did and did not work with the experiment.

As instructors move through the change process, many factors affect their willingness to adopt a new teaching method. These factors include interest in new methods, support from colleagues and administrators, time involved in implementing the new method, research showing the effectiveness of the new method, availability of resources, and the ease or difficulty of implementation (Bennett and Bennett, 2003; Jacobsen, 1998; Rogers, 2003; Sahin, 2006; Gess-Newsome et al., 2003; Henderson, 2005; Henderson et al., 2011; Olitsky, 2015; Pundak and Rozner, 2008). Dissatisfaction with current teaching methods is often considered a prerequisite for change (Gess-Newsome et al., 2003; Henderson, 2005; Olitsky, 2015; Pundak and Rozner, 2008). Personal influence is also considered to be a major factor in the adoption process, particularly for those who adopt later (Rogers and Beal, 1957). Those who adopt early, when an innovation is still new, may not have as many sources of personal influences because few people have adopted the innovation. Those who adopt later on are likely to seek information and
support from early adopters who have more experience with the innovation (Rogers and Beal, 1957).

**Research Questions**

POGIL-PCL workshops are designed to support instructors at various stages of implementation and to involve faculty in developing materials for POGIL-PCL experiments. In this study, we seek to understand what factors influence instructors at different stages of adopting POGIL-PCL. Specifically, the research questions are:

- What factors initially interest instructors in changing their teaching method?
- What factors affect whether instructors adopt new teaching methods?
- To what extent are the workshops effective? Do participants adopt POGIL-PCL experiments after the workshop?

**Methods**

**Workshop Assessment.** At the end of each workshop, participants were asked for their feedback on the strengths of the workshop, the improvements needed for future workshops, and any insights they gained from the workshop. The SII (strength, improvements, and insights) forms were collected at five workshops from January 2012 through January 2014. The responses were analyzed for common themes such as networking, hands-on experience with POGIL, and insights into teaching.

**Survey.** The POGIL-PCL Survey was administered via REDCap (Harris et al., 2009). Participants who attended two-day POGIL-PCL workshops or half-day POGIL-PCL workshops at BCCE between January 2012 and January 2014 were contacted via email and asked to
complete the survey. No identifying information was collected in the survey. Approval for the survey was obtained from the Institutional Review Board at Virginia Commonwealth University on July 29, 2014. The survey was open to workshop participants on September 5, 2014 and closed on October 13, 2014, giving participants approximately five weeks to respond. The response rate was 69% (62 email invitations were sent out; 43 completed responses were obtained). The survey included questions focusing on participants’ experiences and attitudes both before and after the workshop.

Data Analysis. For most of the survey questions, respondents were asked to check all answers that applied. Percentages for each answer choice were calculated from the total number of responses for each question. For several of the questions, there was an “other” response respondents could select if they did not agree with any of the available responses or if they had another response to add. After the survey was closed, the “other” responses were categorized with the provided responses or new categories were created based on common themes in the written answers. For example, for the question “How did you find out about the POGIL-PCL workshop,” several of the respondents who selected “other” stated that they heard about it at a POGIL national meeting or ACS meeting; these responses were placed in the category, “I attended a seminar or meeting in which POGIL-PCL was discussed.” Similarly, several of the respondents who selected “other” stated that they were invited by one of the organizers. These responses were categorized with the response “It was recommended by a colleague,” and the category was expanded to “It was recommended by a colleague, or I was invited by one of the organizers.” For the question, “What made you decide not to use POGIL-PCL,” a common theme among the “other” responses was that the instructor had not taught a lab course since the workshop; a new category was created to include those responses.
Results and Discussion

The questions in the POGIL-PCL Survey were divided into two categories: those that address the factors that initially interest instructors in changing their teaching methods and those that address whether instructors adopt new teaching methods. Responses were analyzed for common themes in order to understand what motivates faculty in the earlier stages (knowledge and persuasion) and later stages (implementation and confirmation) of the change process. The SII responses were also analyzed for common themes related to the survey questions.

SII RESPONSES

Several common themes were seen in the SII responses, such as the value of networking, hands-on experience with POGIL-PCL labs, time to develop experiments, and insights into teaching physical chemistry laboratories. Since participants completed the SII forms before leaving the workshops, the SII forms yield insight into participants’ initial impressions of the POGIL-PCL workshops. Most of the improvements suggested were related to scheduling or organization. Over time, there is a noticeable decrease in the percentage of workshop participants who suggested improvements. For two out of the first three workshops (January 2012 and February 2013), all of the respondents suggested improvements; in June 2012, 50% of the respondents suggested improvements. The percentage decreased to 37% for the July 2013 workshop and 40% for the January 2014 workshop, which suggests that the workshop effectiveness has improved over time. For every workshop, all participants listed multiple strengths, including collaboration or networking with other physical chemistry faculty and the opportunity to experience a POGIL-PCL experiment.
Survey: Initial Factors That Engage Instructors

One of the goals of the survey was to determine what factors initially interest instructors in changing their teaching methods. This goal addresses the knowledge and persuasion stages in the diffusion of innovations theory. While some instructors who attend the workshops may be in the later stages (implementation and confirmation), the goal was to understand instructors’ initial thought processes when they first learned about POGIL-PCL. Three questions on the POGIL-PCL Survey addressed the factors that initially interest instructors to possibly change their teaching methods:

1. How did you find out about the POGIL-PCL workshop?

2. Which of the following describes your reason(s) for coming to a POGIL-PCL workshop?

3. Which of the following would encourage (or has encouraged) you to use POGIL in your lab(s)?

The possible responses and percentages for each response for question 1 (How did you find out about the POGIL-PCL workshop?) are shown in Figure 2. The two most common responses were “I attended a seminar or meeting in which POGIL-PCL was discussed” (44.7%) and “It was recommended by a colleague, or I was invited by one of the organizers” (40.4%). In contrast, a much smaller percentage of respondents selected the response “I read about it on the POGIL website” (6.4%). The data here indicate that actively speaking about the workshop with a person, such as a colleague or a seminar speaker, has a greater influence on an instructor’s decision to come to a workshop and learn more about the POGIL-PCL than passive, impersonal communication such as reading about the workshop on the website. Rogers and Beal, as well as Jacobsen, also found that personal influence was a major factor in an individual’s decision to adopt change (Jacobsen, 1998; Rogers and Beal, 1957). Rogers and Beal argue that impersonal
communication (like mail) is easy to ignore and that individuals who are unsure about a new idea are more likely to be reached by person-to-person communication (Rogers and Beal, 1957).

![Graph showing responses to the question, "How did you find out about the POGIL-PCL workshop?"
](#)

**Figure 2.** Percent of total responses for the question, “How did you find out about the POGIL-PCL workshop?” Respondents were asked to select all answers that applied.

Another question addressed instructors’ reasons for coming to a workshop. The top three responses in Figure 3 were given in the survey; the bottom three responses were common themes among respondents who selected “other.” The belief that students do not get much from traditional labs or experiments, the desire for students to be active learners, and feeling that students are more concerned with getting the correct answer than the process of learning accounted for over 90% of the responses. A desire to get students more engaged in lab and involved in the process of learning appears to play an important role in instructors’ decision to come to a workshop, although the workshop itself may have influenced respondents’ answers to this question. The survey responses are consistent with the discussion at the workshops and with the ultimate design of the POGIL-PCL experiments, as illustrated in Figure 1, that arose out of these workshop discussions. Comments from instructors also supported this conclusion. One instructor commented, “I wanted access to labs that are more appropriate for upper level labs-
that get students to think about what they are doing, why they are doing it, and what the results mean.” Another instructor commented, “I want my students to learn to think. Thinking rarely seems to occur in traditional labs.”

![Graph showing reasons for coming to a POGIL-PCL workshop](image)

**Figure 3.** Percent of total responses for the question, “Which of the following describes your reason(s) for coming to a POGIL-PCL workshop?” Respondents were asked to select all answers that applied.

The third question addresses the factors that encourage instructors to implement POGIL-PCL in their laboratory. Instructors’ responses are shown in Figure 4. Research and statistics showing the effectiveness and long-term benefits of POGIL had a large impact on instructors’ decisions to implement POGIL; however, hands-on experience with POGIL labs or experiments received the highest response rate (22.0%). Hands-on experience was also a common theme among the strengths participants cited on the SII forms. The hands-on experience provided at the workshops allow instructors to see how the experiments work from the student’s perspective and to observe how those who currently use POGIL in their lab courses facilitate the experiments. This experience is a key component of the third, or decision, stage of Roger’s theory of the diffusion of change (Rogers, 2003). Another study also emphasized the importance of hands-on experience at workshops (Burke et al., 2004). Again, direct personal influence was also a factor
in encouraging instructors to implement POGIL. Personal influence in this case occurred during and after the workshop in the form of support from the POGIL community, learning about POGIL from colleagues, and interacting with other physical chemistry faculty.

Figure 4. Percent of total responses for the question, “Which of the following would encourage (or has encouraged) you to use POGIL in your lab(s)?” Respondents were asked to select all answers that applied. (The last answer, “personal experience using POGIL in lab,” was a common theme among those who selected “other.”)

Survey: Factors That Affect Whether Instructors Adopt New Teaching Methods

To understand the factors that affected whether instructors implemented POGIL, survey respondents were asked, “After the POGIL-PCL workshop, how have you used POGIL in your lab(s)?” The goal here was to determine if instructors moved into the implementation stage after attending the workshop. If a respondent indicated they had used POGIL at all, they were asked what types of follow-up would be helpful to them. If they indicated they had not used POGIL since the workshop, respondents were asked what made them decide not to use POGIL.

Table 1 shows the percentages, sorted by frequency, of instructors who had used POGIL in their lab. Of the instructors who responded, 76.8% had used POGIL to some extent in their lab. (“To some extent” refers to the sum of the categories “mostly used POGIL labs,” “used POGIL labs regularly,” and “tried a few POGIL labs.”) As shown in Figure 5, email/Skype with
POGIL facilitators and follow-up workshops were the most commonly selected forms of support. Personal influence was a key factor in motivating instructors to change their teaching methods; the responses here indicate personal influence is also an important factor when instructors are making the decision to implement POGIL. Burke et. al. (2004) also found that many workshop participants value the interaction provided at workshops, as it allows them to network with colleagues in their field and discuss challenges associated with implementation with more experienced practitioners.

**Table 1.** Percentage of Respondents Who Use POGIL at Each Frequency

<table>
<thead>
<tr>

<tr>
<td>Do not use POGIL labs</td>
<td>23.3%</td>
</tr>
</tbody>
</table>

**Figure 5.** Percent of total responses for the forms of support (email/Skype, follow-up workshops, or visiting with a facilitator or experienced POGIL practitioner) that would be helpful for instructors as they begin to implement POGIL. Respondents were asked to select all answers that applied.

Of the respondents who said they had not used POGIL since the workshop, the most commonly cited reason was that the instructor had not taught a lab course since the workshop (57.1%), followed by the course being taught round-robin style (28.6%). Using POGIL-PCL in a round-robin format could be an area for future study, given that a round-robin setting does
provide some logistical challenges because POGIL-PCL experiments rely heavily on collaboration both within and between groups of students.

Survey respondents were also asked about their past experience with POGIL. Instructors were asked to recall whether their experiences had been mostly positive, somewhat positive due to either issues with the activities or resistance from students and/or other faculty, or if they had a lot of difficulty with the activities or resistance from student and/or other faculty. Over fifty percent of the survey respondents reported that their experience had been mostly positive. Given that instructors were more encouraged to implement POGIL in their laboratory when they had hands-on experience with the experiments, it seems that prior experience with POGIL would have an effect on an instructor’s decision to use POGIL-PCL experiments. It was hypothesized that instructors whose prior experience was more positive would be more likely to use POGIL-PCL experiments. Figure 6B shows that, when instructors reported having a mostly positive experience in the past, 83.3% had used POGIL-PCL experiments to some extent, with 31.8% mostly using POGIL-PCL experiments. (Again, “to some extent” refers to the sum of the categories “mostly used POGIL labs,” “used POGIL labs regularly,” and “tried a few POGIL labs.”) However, for instructors whose experience was not mostly positive (i.e. somewhat positive or a lot of difficulty), 66.7% had used POGIL-PCL experiments to some extent, and only 4.8% were mostly using POGIL-PCL experiments. As expected, those who had a more positive experience with POGIL before coming to the workshop were more likely to try POGIL-PCL after the workshop.
It should be noted, however, that, even when instructor’s experience was not mostly positive, some still chose to try POGIL-PCL after attending the workshop. Despite reporting difficulty with the activities and/or resistance from students and/or faculty in the past, 66.7% of instructors (Figure 6B) had chosen to use POGIL-PCL experiments, with sizable percentages having tried a few experiments or regularly using the experiments in their labs. This result speaks to the effectiveness of the workshops. Although some instructors recalled less than positive experiences with POGIL in the past, they chose to attend a workshop and decided to try some of the experiments.
Open Questions

There are several remaining questions regarding the workshops and the adoption of POGIL-PCL. Several instructors reported that they had not used POGIL-PCL experiments because they have not taught a laboratory course since the workshop. This study was conducted 7 months after the last workshop. Lewis and Lewis (2006) conducted a study on workshop effectiveness more than a year after the last workshop in a series of workshops and still found that a larger percentage of participants from the last workshop reported planned use of the activities rather than actual use (compared to participants from earlier workshops). This brings up the question of how long to wait after workshops are conducted to administer an implementer’s survey. Conducting a survey too early means that some participants will not have had a chance to implement the new teaching method; however, waiting too long may make it more difficult to capture instructors’ initial impressions and influences. In our case, more than 75% of survey respondents had used the experiments in their laboratories. Another follow-up survey would need to be done to determine whether that percentage would be significantly different if the survey were conducted at times long after the workshops attended.

There is also the question of whether instructors will continue to use POGIL years after they have attended the workshops. Five or ten years after their initial decision to implement POGIL, will instructors still be using POGIL-PCL? One study by Stains et al. (2015) found that, while instructors who attended workshops changed their teaching methods immediately after attending a workshop, these changes were not sustained a year later. In this study, the responses from instructors, particularly those regarding their reason for coming to a POGIL-PCL workshop, indicate that workshop participants believe in the goals of the POGIL-PCL project. Future studies will be necessary to determine how many instructors continue to use POGIL-PCL.
One question that is perhaps more difficult to answer is how instructors who have attended the workshops implement POGIL-PCL experiments. Do they implement the experiments as written, or do they modify them? How do different instructors facilitate the experiments? These questions can be answered to a certain extent by asking instructors about their implementation and has been addressed in a follow-up survey. When viewed collectively rather than individually, self-assessments can provide some indication of workshop success (D’Eon et al., 2008). Faculty could also be interviewed individually or in focus groups. However, it is difficult to fully answer these questions without observing individual instructors because faculty are self-reporting their activities. Alternatively, faculty could be observed teaching their courses using an observation rubric developed for laboratory courses (Smith et al., 2013; Lund et al., 2015; Piburn et al., 2000).

Conclusion

The POGIL-PCL survey was designed to uncover factors that initially interested instructors in changing their teaching methods and factors that affected whether instructors adopted new teaching methods. The data collected from the survey show that personal influence (contact with colleagues, seminar speakers, facilitators, and other members of the POGIL community) is an important factor in the early stages of adoption when instructors are becoming aware of POGIL-PCL and deciding to learn more about it (knowledge and persuasion) and in the later stages of adoption when instructors begin to implement POGIL-PCL. While instructors who attend the workshops are in different stages of the process of change, 76.8% of instructors who responded to the survey moved into the implementation stage to some extent. Instructors’ initial experience with POGIL also heavily influenced their decision to use POGIL-PCL; of
those who had a mostly positive experience 31.8% were mostly using POGIL-PCL, compared with only 4.8% of those whose experience was not mostly positive.

Several open questions have been discussed, including how long to wait after the workshop to conduct a survey and how different instructors implement POGIL in their laboratory courses. A follow-up survey has been conducted to address these questions. Future papers will discuss results of this follow-up survey and focus on the development of a POGIL-PCL network over time.

Appendix 2 (screening rubric)

Laboratory Experiment Initial Screening Rubric, POGIL-PCL (Cole and Bauer, 2012)

This rubric guides initial review of a laboratory experiment to determine how well the activity supports process-oriented and guided-inquiry learning in the physical chemistry laboratory. The review pertains only to the written description of the experiment, protocol, and pre/post lab questions included and not to how an instructor might facilitate its use. A “yes” response should indicate that evidence for that characteristic can be found in the activity itself. The evidence must be explicit, i.e. reviewers should not assume that an instructor using the activity will provide anything that seems to be missing. If evidence is found, then a “yes” response is appropriate, irrespective of the perceived quality of that characteristic. If no explicit evidence can be found, then a “no” response is appropriate.

<table>
<thead>
<tr>
<th>ESSENTIAL CHARACTERISTICS</th>
<th>Yes</th>
<th>No</th>
<th>Comments --</th>
</tr>
</thead>
<tbody>
<tr>
<td>1  The experiment begins with a conceptual question, typically as the title of the experiment.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2  The expected outcome of the experiment and concepts developed are known to the instructor but not to the students.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3  The learning objectives incorporate the knowledge and skills needed for students to answer the conceptual question.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4  The experiment follows the POGIL-PCL template: pre-experiment questions, experimental protocol, thinking about the data questions, and post-experiment questions. More than one cycle, based on one experimental protocol, of pre-experiment, TATD, and post-experiment questions is preferable.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5  Students develop a hypothesis, model and/or conclusion that integrates available information and/or prior knowledge and can be convincingly justified.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>6  Students are expected to engage in problem solving, decision-making, and/or experimental design tasks.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>7  Students are expected to observe, collect and process information (describe, tabulate, summarize, calculate, and/or transform data to another representation).</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>8  Students are led to apply mathematical models to data; when appropriate, students are guided to model data graphically in order to obtain results.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>9  Students demonstrate their understanding of the developed concepts through application and/or by developing questions for further research.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>10 Students are cued to share or interact with each other, including coming to consensus on key experimental design or data analysis decisions.</td>
<td></td>
<td></td>
<td></td>
</tr>
