Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about *Accepted Manuscripts* in the **Information for Authors**.

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard <u>Terms & Conditions</u> and the <u>Ethical guidelines</u> still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

# MnO₂nanoflakes/polyaniline nanorods hybrid nanostructures on graphene paper for high-performance flexible supercapacitor electrodes

HuailongLi<sup>a</sup>, Ying He<sup>a,\*</sup>, Vladimir Pavlinek<sup>b</sup>, Qilin Cheng<sup>a,b\*</sup>, Petr Saha<sup>b</sup>, Chunzhong Li<sup>a</sup>

A facile two-step strategy is adopted to construct free-standing composite paper of MnO $_2$  nanoflakes/polyaniline (PANI) nanorods hybrid nanostructures on reduced graphene oxide (RGO) for flexible supercapacitor electrode application.MnO $_2$  nanoflakes are firstly grown on RGO paper via electrodeposition method, followed by assembly of PANI nanorods between MnO $_2$  nanoflakes by in situ polymerization using camphorsulfonic acid as dopant. The morphology and structure of composite paper are characterized and the electrochemical properties are systematically investigated. The interconnected PANI nanorods deposited on the interlaced MnO $_2$  nanoflakes have a length of ~100 nm and diameter of ~30 nm, creating plenty of open porous structures which are beneficial for ion penetration into the electrode. The RGO/MnO $_2$ /PANI composite paper shows a large specific capacitance of 636.5 F g<sup>-1</sup> at 1.0 A g<sup>-1</sup> in 1.0 M Na $_2$ SO $_4$  electrolyte and excellent cycling stability (85% capacitance retention after  $10^4$  cycles). The optimized composite structure with more electroactive sites, fast ion and electron transfer, and strong structural integrity endows the ternary composite paper electrode with outstanding electrochemicalperformance.

# Introduction

Nowadays, energy and environmental issues have become increasingly prominent due to the rapid growth of economy. To address these problems, considerable work has been devoted to searching renewable and clean energy as well as efficient energy storage and conversion technologies<sup>1-3</sup>. Supercapacitors (SCs), as one of the most important energy storage systems, have received a great deal of interest for their large power density, fast charge-discharge rate and long cycling life and safety. Recently, flexible, lightweight and highly efficient energy devices have become very popular in the modern markets. As such, flexible SCs have aroused significant attention due to their lightweight, small size, ease of handling, and high-flexibility <sup>4</sup>, as compared with conventional SCs. To date, much effort has been put into design and preparation of flexible SCs, and significant progress has been made 5-7. Nevertheless, the energy storage densities of flexible SCs still have yet to be further improved to meet their practical

The performance of flexible SCs significantly depends on the structure and electrochemical activities of electrode materials. An ideal flexible electrode material should have good electrochemical properties, great mechanical strength upon bending or folding, and balanced porous structure to adapt large strain without any loss of performance<sup>8</sup>. In this regard, carbon materials have brought substantial opportunities over the past few years for developing advanced flexible electrodes owing to their good conductivity, high surface area and favorable mechanical integrity 9,10. Especially, graphene-based flexible electrodes have received intensive interest because of their excellent electrochemical stability, good structural, electrical and mechanical properties Recently, this research filed is focused on the synthesis of freestanding, binder-free and flexible electrodes by assembling individual RGO nanosheets into a macroscopic RGO-based papers (or films) 12-14. However, the drawbacks during its processing are also obvious, that is, irreversible agglomeration and restacking of graphene nanosheets and low specific surface area of the paper (or film) 15, which inevitably lead to low specific capacitance and poor cycling stability of graphenebased paper electrodes.

One effective way to solve such problems is to assemble pseudocapacitive materials (e.g. conducting polymers and metal oxides) on RGO paper to construct high performance composite electrodes. The special synergistic effects between

ARTICLE Journal Name

RGO and pseudocapacitive materials may endow composite electrodes with high conductivity, large specific capacitance, and relatively high accessible surface area, and thus improve their energy density, power density, and cycling life. In such a case, various electroactive materials such as MnO<sub>2</sub><sup>8,16</sup>, Fe<sub>3</sub>O<sub>4</sub><sup>17</sup>, PANI <sup>18,19</sup>, and polypyrrole<sup>20</sup> grown on RGO substrate for flexible SCs applications have been developed. More recently, in order to get flexible electrodes with better electrochemical performance, combination of the flexible substrate with two electroactive materials into a ternary composite system <sup>21-23</sup> has become a hot research spot. Of the pseudocapacitive materials, MnO<sub>2</sub> and PANI are the two most common classes of electrode materials for SCs applications owing to their respective advantages in electrochemical activity. Therefore, it is naturally expected to achieve optimal performance by rationally designing RGO/MnO<sub>2</sub>/PANI ternary composite electrode. However, the great challenge here is to construct an optimum electrode architecture which not only provides rich accessible active area for electrochemical reaction, but facilitates the kinetics of ion/electron transport throughout the electrode.

Herein, we develop a facile two-step strategy to design and fabricate novel ternary composite by assembling MnO<sub>2</sub>/PANI heterostructured nanocomposite on RGO paper for high performance flexible SCs. MnO<sub>2</sub> nanoflakes are firstly grown on RGO paper via electrodeposition method and then PANI nanorods are embedded between intersecting MnO<sub>2</sub> nanoflakes by chemical oxidative polymerization. This unique nanoarchitecture ensures a fast electron transfer, a short ion transport/diffusion path, and more electrochemical active sites. Based on the optimizing structure and fascinating synergistic effect between individual component, the flexible RGO/MnO<sub>2</sub>/PANI composite paper electrode exhibits significantly enhanced electrochemical properties, such as much high specific capacity (636.5 F g<sup>-1</sup> at 1.0 A g<sup>-1</sup>), superior cycling stability (85% capacitance retention after 10<sup>4</sup> cycles) and good rate capability.

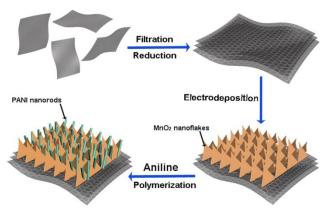

Fig. 1 Schematic illustration of the preparation process of RGO/MnO<sub>2</sub>/PANI nanocomposite.

# **Experimental**

## **Materials**

Hydroiodic acid (57 wt.% in  $H_2O$ ), the Anopore inorganic membrane (47 mm in diameter and 0.2  $\mu$ m in pore size) and camphorsulfonic acid (CSA, 98%) were supplied by Sigma Aldrich. Graphite flakes (2-15 $\mu$ m) were obtained from Alfa-Aesar company. Aniline bought from Shanghai Chemical Reagent Co. was distilled under vacuum before use. Ammonium persulfate (APS, 98%) and other chemicals were used as received.

# Synthesis of RGO paper and RGO/MnO₂nanoflakes composite paper

GO were synthesized by the modified Hummers method <sup>24</sup>. RGO paper was then obtained using hydroiodicacid (HI) as the reducing agent by the following procedure. First, 25 mg of GO was ultrasonically dispersed in distilled water (50 mL) for 2 h, followed by the filtration to produce a GO paper. After drying in the air, the GO paper was peeled from the filter and immersed into the hydroiodic acid (45%) at 85 °C for 3 h. Finally, the RGO paper was obtained by washing with distilled water and ethanol. The RGO/MnO2 composite paper was prepared by electrodepositing of MnO<sub>2</sub> on the RGO paper (1 × 2 cm²). All electrodeposition experiments were performed on an Autolab PGSTAT-302N electrochemical workstation (Metrohm, Netherlands) with a standard three-electrode cell, where a RGO paper was the working electrode, a platinum plate and an Ag/AgCl used as the counter electrode and reference electrode, respectively. The electrodeposition of MnO<sub>2</sub> nanoflakes was performed in aqueous solution containing 0.1 M Mn(CH<sub>3</sub>COO)<sub>2</sub> and 0.1 M Na<sub>2</sub>SO<sub>4</sub> at a voltage of 0.8 V, and the deposition time was 5 min. Subsequently, the RGO/MnO<sub>2</sub> composite was washed with water and dried at 25 °C.

# Synthesis of RGO/PANI and RGO/MnO<sub>2</sub>/PANI composite paper

0.6 mL of aniline was injected into 40 mL of 0.1 M CSA solution, 20 mL of 0.4 M APS solution was then rapidly added into the above solution under stirring. After being stirred vigorously for 2 min, the RGO paper and RGO/MnO<sub>2</sub> composite paper was dipped into the mixture respectively very carefully without stirring and kept for another 6 h at room temperature. After quick rinsing with water, the resultant RGO/PANI and RGO/MnO<sub>2</sub>/PANI papers were placed in the air overnight and then dried at 60 °C for 2h under vacuum.

## Materials characterization and electrochemical measurements

The morphology of the samples was investigated using a field-emission scanning electron microscope (FE-SEM, HITACHI S4800) and transition electron microscopy (TEM, JEOL 2100F). The specific surface area of samples was measured using the methylene blue adsorption method conducted on a UV-vis spectrometer (UNICO UV-2102PC) at room temperature. Raman spectra were measured on an Acton Raman spectrometer using a 531.4 nm laser as the excitation source. Fourier transformation infrared spectra (FTIR) of the samples were measured from KBr sample pellets on a Nicolet 5700 spectrometer. X-ray photoelectron spectroscopy(XPS) spectra

Journal Name ARTICLE

were examined on an AXIS Ultra DLD spectrometer (Kratos Analytical Ltd.) using a monochromatized Al Ka X-ray source (1486.71 eV). The electrochemical properties of the materials were measured by a three-electrode cell in 1.0 M Na<sub>2</sub>SO<sub>4</sub> electrolyte on an Autolab PGSTAT-302N electrochemical workstation at room temperature. The RGO paper or RGObased composite paper was used as the working electrode, an Ag/AgCl and a platinum plate were used as reference and counter electrodes, respectively. Cycle voltammetry (CV) and galvanostatic charge-discharge (GCD) curves were recorded from-0.1 to 0.9 V. The specific capacitance derived from GCD curves was derived from the discharged time in light of the following equation:  $C=(I \Delta t)/(m \Delta V)$ , where I is the discharged current (A),  $\Delta t$  is the discharged time (s), m is the mass of the electroactive materials (g), and  $\Delta V$  is the potential (V). Electrochemical impedance spectroscopy(EIS) was investigated in the frequency range of 10<sup>5</sup>–0.01 Hz.

# **Results and discussion**

Fig. 1 depicts the two-step synthesis strategy of MnO<sub>2</sub>/PANI hybrid nanostructures on RGO paper. First, MnO<sub>2</sub> nanoflake arrays were electrodeposited on the RGO paper within a mixed aqueous solution of Mn(CH<sub>3</sub>COO)<sub>2</sub> and Na<sub>2</sub>SO<sub>4</sub>. Then PANI nanorods were grown onto the MnO<sub>2</sub> nanoflake backbone via an oxidative polymerization method assisted by CSA dopant to form a hierarchically ternary composite. Both MnO<sub>2</sub> and PANI are employed as active materials, while the conductive RGO paper as a current collector guarantees effective ion and electron transport throughout the electrode.

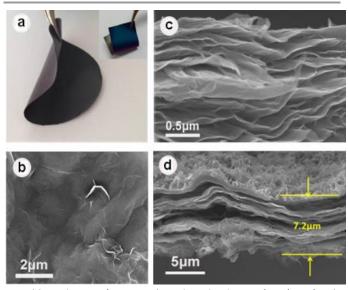

Fig. 2 (a) Digital images of RGO paper (inset shows digital image of RGO/MnO $_2$ /PANI), SEM images of (b) RGO paper, (c) cross-sectional view of RGO paper and (d) cross-sectional view of RGO/MnO $_2$ /PANI.

The digital photographs in Fig. 2a show a free-standing RGO paper with dark-grey color. The obtained RGO paper exhibits high conductivity (14.5  $\Omega$  sq<sup>-1</sup>) and light weight (1.35 mg cm<sup>-2</sup>). After growth of MnO<sub>2</sub>/PANI composite, the surface of RGO paper becomes blue-green (inset of Fig. 2a). Both RGO

paper and RGO-based composite paper are very flexible and bendable, as shown in Fig. 2a. SEM image (Fig. 2b) of RGO paper indicates curved and wrinkled features on its surface, which are in favor of  $MnO_2$  deposition. Fig. 2c further confirms that the RGO paper consists of densely layered sheets, which guarantee a high flexiblity and good mechanical strength of RGO paper. After a thin layer of  $MnO_2/PANI$  composite grown on RGO paper, the layered feature of RGO and  $MnO_2/PANI$  with one-dimensional nanostructure are clearly observed in Fig. 2d, where the  $MnO_2/PANI$  are well grown on the surface of RGO to form a tightly compact structure with thickness of  $\sim\!\!7.2~\mu m.$ 

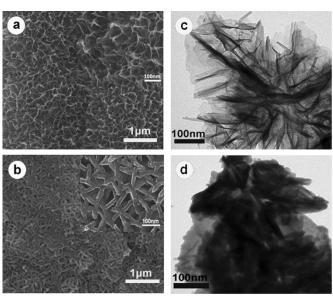

Fig. 3 SEM images of (a) RGO/MnO<sub>2</sub> and (b) RGO/MnO<sub>2</sub>/PANI. TEM images of (c) MnO<sub>2</sub>nanoflakes and (d) MnO<sub>2</sub> nanoflakes/PANI nanorods. The insets in (a) and (b) show high-magnifications of respective SEM images.

Fig. 3a shows the uniform growth of MnO<sub>2</sub> nanoflake arrays on the surface of RGO. The high-magnification SEM image (Fig. 3a, inset) reveals that the ultrathin nanoflakes are interlaced with each other and create abundant void spaces which ensure fast penetration of electrolyte ions into the inner of electrode materials. It is worth noting that numerous interconnected PANI nanorods are anchored on the MnO<sub>2</sub> skeletons by chemical polymerization of aniline, as evidenced by Fig. 3b. A high-resolution image (Fig. 3b, inset) indicates that the PANI nanorods with length of~100 nm and diameter of ~30 nm are embedded into the space between MnO2 nanoflakes without destroying porous structures, which can benefit the transportation of the electrons and increase more electroactive surfaces. To further investigate the morphology of active materials on RGO paper, TEM images are also presented. Fig. 3c illustrates that the leaf-like ultrathin MnO<sub>2</sub>nanoflakes with thickness of ~5 nm are deposited on the RGO paper, in good agreement with SEM observation. While Fig. 3d demonstrates the presence of large amounts of rod-like PANI nanaostructures on MnO<sub>2</sub> nanoflakes. In addition, SEM image (Fig. S1) of RGO/PANI paper indicates that PANI nanorods are grown aggregately on the RGO paper, which may

ARTICLE Journal Name

reduce the utilization of PANI during the electrochemical reaction.

The specific surface areas of RGO, RGO/MnO<sub>2</sub>, and RGO/MnO<sub>2</sub>/PANI were measured to be 108.6, 87.1 and 78.1  $\rm m^2\,g^{-1}$ , respectively. Although the specific surface areas of both composite papers decrease a little bit after deposition of MnO<sub>2</sub> and MnO<sub>2</sub>/PANI nanostructures respectively on the RGO paper, the values are comparable to those of other free-standing and flexible materials.

The existence of MnO<sub>2</sub> and PANI in the ternary composite can be confirmed by the FT-IR and Raman spectra (Fig. 4). The FT-IR spectrum of pristine RGO paper shows typical characteristic peaks of graphene. The strong peaks at 874, 1417, 2852 and 2925 cm<sup>-1</sup> correspond to lateral vibrations of CH<sub>2</sub>, deformation vibrations of C-OH, CH<sub>2</sub> symmetric and asymmetric stretching vibrations , respectively <sup>25</sup>. Whereas the weak peaks at 1064, 1247, and 1621 cm<sup>-1</sup> are assigned to the C-O stretching vibrations of alkoxy and epoxy groups<sup>26</sup>, and skeletal vibration of graphene 27, respectively. In case of RGO/MnO<sub>2</sub>, the broad peak at ~ 3400 cm<sup>-1</sup> is ascribed to the H-O-H bending of absorbed H<sub>2</sub>O molecules. In addition, the peaks at 400-800 cm<sup>-1</sup> are related to Mn-O stretching vibrations, indicating the presence of MnO<sub>2</sub> in the RGO/MnO<sub>2</sub> composite <sup>28</sup>. Meanwhile, the characteristic peaks of graphene are still observed except that the intensity is weakened due to the deposition of MnO2 nanoflakes on the surface of RGO paper. As for RGO/MnO<sub>2</sub>/PANI composite, two typical peaks at 1490 and 1579 cm<sup>-1</sup> represent C=C stretching vibrations of the benzenoid and quinonoid rings, respectively. The other peaks at 819, 1148, 1237, and 1294 cm<sup>-1</sup> correspond to the out-ofplane bending of C-H, in-plane bending of C-H, C=N stretching mode, and C-N stretching vibration, respectively<sup>29</sup>. These characteristic peaks are in agreement with the features of pure PANI, demonstrating the formation of PANI in the RGO/MnO<sub>2</sub>/PANI composite. However, the peaks of MnO<sub>2</sub> and RGO become weak owing to the growth of PANI nanorod networks on RGO/MnO<sub>2</sub> composite paper. The appearance of PANI and MnO<sub>2</sub> in the ternary composite can be also verified by the Raman spectra (Fig. 4b). The RGO paper exhibits two distinct peaks at 1352 and 1591 cm<sup>-1</sup> which are assigned to broad D and G bands, respectively. The high intensity of D peak implies the presence of residual oxygen functional groups and other defects <sup>30</sup>, which is in accordance with the result of its FT-IR spectrum. A strong peak in 480-680 cm<sup>-1</sup> region is connected with to Mn-O stretching vibration <sup>28</sup>, indicating the presence of MnO<sub>2</sub> in the RGO/MnO<sub>2</sub> binary composite paper. In contrast, the curve of RGO/MnO<sub>2</sub>/PANI composite shows obvious peaks corresponding to PANI: the peaks at 1174 and 1565 cm<sup>-1</sup> are related to the C-H bending and the C=C stretching of the quinoid ring, respectively. The peak at 1248 cm<sup>-1</sup> is associated with the C-H bending of the benzenoid ring, and the peak at 1342cm<sup>-1</sup> is referred as C-N<sup>+</sup> stretching vibration <sup>31</sup>. The weak or invisible peaks of MnO<sub>2</sub> and RGO in the Raman spectrum of RGO/MnO<sub>2</sub>/PANI are caused by the masking effect of PANI.

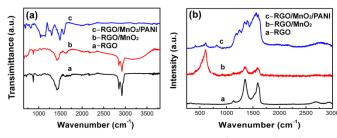

Fig. 4 (a) FT-IR spectra and (b) Raman spectra of RGO, RGO/MnO<sub>2</sub>, RGO/MnO<sub>2</sub>/PANI.

Compositional analysis and surface electronic state of the elements of RGO/MnO<sub>2</sub>/PANI composite paper were performed by means of XPS (Fig. 5). The XPS analysis of Fig. 5a indicates the presence of C, N, O and Mn elements in the obtained ternary composite. Fig. 5b illustrates the XPS spectrum of C1s spectra which can be resolved into three peaks centered at 284.5 (C-C), 285.3 (C-N) and 286.5 (C-O)<sup>32</sup>. The relatively weak signal of C-O reflects effective reduction of GO to RGO. For N 1s spectrum (Fig. 5c), the main peak is devided into three peaks corresponding to various eletronic state: the nitrogen cationic radical at 400.1 eV (N++), the quinoid amine at 399.5 eV and the benzenoid amine at 397.5 eV (-N=) 33. Based on the above-mentioned analysis, the doped state of PANI is formed in the composite. Fig. 5d presents the high-resolution Mn 2p spectra, where the peaks at 642.05 and 653.85 eV with a spin energy separation of 11.8 eV correspond to Mn  $2p_{3/2}$  and Mn  $2p_{1/2}$ , respectively, which is similar to those previously reported for MnO<sub>2</sub> <sup>34,35</sup>.

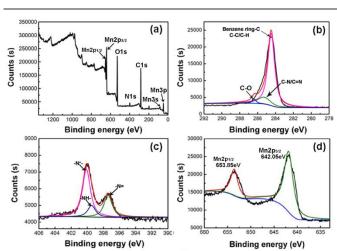

Fig. 5 (a) Wide scan survey XPS spectrumof RGO/MnO<sub>2</sub>/PANI, (b) XPS C1s spectra of RGO/MnO<sub>2</sub>/PANI, (c) XPS N1s spectra of RGO/MnO<sub>2</sub>/PANI, (d) XPS Mn2p spectra of RGO/MnO<sub>2</sub>/PANI.

To evaluate the electrochemical capacitive behavior of RGO/MnO<sub>2</sub> nanoflakes/PANI nanorods ternary composite paper as flexible and free-standing electrode for SCs, cyclic voltammetry (CV), galvanostatic charge/discharge (GCD) and electrochemical impedance spectroscopy(EIS) were performed with a three-electrode system in 1.0 M Na<sub>2</sub>SO<sub>4</sub> solution within the potential window of -0.1 $\sim$ 0.9 V. As the hierarchical MnO<sub>2</sub>/PANI nanostructures grown on the RGO, the RGO/MnO<sub>2</sub>/PANI composite papers are expected to exhibit

Journal Name ARTICLE

excellent performance as flexible SCs electrode materials. In order to clarify the effect of the ratios of the three components on the specific capacitance, the ternary composites with various mass percentage of RGO, MnO2 and PANI were measured by GCD at 1.0 A g<sup>-1</sup> (Fig. S2a), and the specific capacitance of composites are plotted in Fig. S2b. An appropriate ratio of three components is important for the RGO/MnO<sub>2</sub>/PANI composite with optimal performance. The composite with 52.7% RGO, 36.7%  $MnO_2$  and 10.6% PANI possesses the maximum specific capacitance of 636.5 F g<sup>-1</sup>. While the PANI content further increases beyond 17.3%, the capacitance of the composite decrease significantly. The excess PANI nanorods not only block up the open spaces in the composite but also reduce the active areas, which inevitably weaken the electrochemical performance of the ternary composite. Therefore, the mass percentage of RGO, MnO<sub>2</sub> and PANI in the RGO/MnO<sub>2</sub>/PANI composite in our experiment is controlled at 52.7%, 36.7% and 10.6%, respectively.

Fig. 6a shows the CV curves of the RGO/MnO<sub>2</sub> composite paper measured at various scan rates. A pair of weak redox peaks can be observed in the CV curves at lower scan rates due to the reaction  $(MnO_2 + Na^+ + e^- = MnOONa)$  of  $MnO_2$  in composite electrode <sup>36</sup>. These CV curves are nearly rectangular, reflecting good capacitive performance and excellent reversibility of RGO/MnO2 composite paper electrodes. However, at higher scan rates (e.g. 100 mV s<sup>-1</sup>), the CV profile deviates much from rectangle and no evident redox peaks are observed. These phenomena are attributed to the polarization of the desolvation process of the hydrated sodium ions and relatively low conductivity of MnO<sub>2</sub> on RGO paper<sup>37</sup>. In comparison to RGO/MnO<sub>2</sub> binary composite, the RGO/MnO<sub>2</sub>/PANI ternary composite exhibits the characteristic quasi-rectangular shapes with perceptible redox peaks at all scan rates from 5 to 200 mV  $\rm s^{-1}$  (Fig. 6b). This is because PANI nanorod networks embedded into the MnO<sub>2</sub>nanoflakes further improve the electrical conductivity of the composite and also increase the contact area between electrode and electrolyte, which is in favor of charge transfer and ion transport.

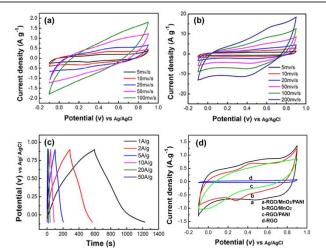

Fig. 6 CV curves of (a) RGO/MnO $_2$  and (b) RGO/MnO $_2$ /PANI at different scan rates, (c) GCD profiles of RGO/MnO $_2$ /PANI at various current densities, (d) CV curves of RGO, RGO/PANI, RGO/MnO $_2$  and RGO/MnO $_2$ /PANI at the scan rate of 20 mV s $^{-1}$ .

Fig. 6c presents GCD curves of the as-synthesized composite paper electrode. All the charge and discharge curves show nearly linear and symmetric at various current densities (1-50 A g<sup>-1</sup>), and a fast I-V response implies good capacitive behavior of RGO/MnO<sub>2</sub>/PANI composite paper electrode. Even at large current density of 50 A g<sup>-1</sup>, the GCD curves are also close to symmetrical charge/discharge profiles with small deviations from linearity, suggesting fast diffusion of ions and low equivalent series resistance (ESR) <sup>38</sup>. To further evaluate the role of MnO<sub>2</sub> and PANI, CV curves of RGO paper, RGO/MnO<sub>2</sub>, RGO/PANI and RGO/MnO<sub>2</sub>/PANI composite are carried out under the same scan rate of 20 mV s<sup>-1</sup>, as shown in Fig. 6d. The CV curve of pristine RGO paper is in rectangular shape, demonstrating ideal capacitive behavior based on electrical double layer charge storage. After incorporation of MnO<sub>2</sub> nanoflakes, PANI nanorods and MnO<sub>2</sub>/PANI nanostructures into RGO substrate, respectively, binary and ternary composites show much larger integrated area within the current-potential curves than RGO, indicating significantly improved capacitance due to the presence of MnO<sub>2</sub> and PANI pseudocapacitive materials. Moreover, the integrated area increases in the order of RGO<RGO/PANI<RGO/MnO2 <RGO/MnO<sub>2</sub>/PANI, demonstrating the higher specific capacitance of ternary composite than that of binary composite. The cross-linked PANI nanostructures embedded into the space between the MnO2nanoflakes not only reduce the internal resistance of composite electrode and increase the active surface areas for pseudocapacitive reactions, but also provide a pathway for continuous charge transfer. In addition, PANI nanorods grown on the surface of MnO2 nanoflakes can effectively restrain the MnO<sub>2</sub> particles from in the electrolyte and thus electrochemical utilization. Therefore, the ternary composite possesses the highest specific capacitance among the three materials.

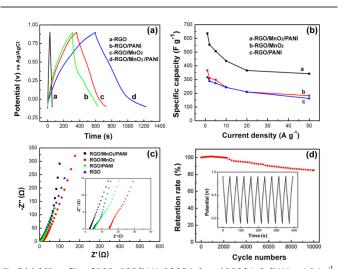

Fig. 7 (a) GCD profiles of RGO, RGO/PANI, RGO/MnO<sub>2</sub> and RGO/MnO<sub>2</sub>/PANI at 1.0 A g<sup>-1</sup>, (b) Specific capacitances of RGO/PANI, RGO/MnO<sub>2</sub> and RGO/MnO<sub>2</sub>/PANI at different current densities, (c) Nyquist plots of RGO, RGO/PANI, RGO/MnO<sub>2</sub> and RGO/MnO<sub>2</sub>/PANI, inset is the enlarged section of Nyquist plots in the high frequency region, (d) Cycling stability of RGO/MnO<sub>2</sub>/PANI at a current density of 20 A g<sup>-1</sup>, inset shows the last 10 cycles of the charge-discharge curves.

ARTICLE Journal Name

To further evaluate the contribution of MnO<sub>2</sub>/PANI hierarchical composite on RGO paper as flexible electrode, the GCD curves of RGO, RGO/PANI, RGO/MnO<sub>2</sub>, RGO/MnO<sub>2</sub>/PANI measured at the current density of 1.0 A g <sup>1</sup>are plotted in Fig. 7a. As expected, the RGO/MnO<sub>2</sub>/PANI composite electrode possesses the longest discharge time, indicating the highest specific capacitance which is calculated to be 636.5 F g<sup>-1</sup> at 1.0 A g<sup>-1</sup>, much higher than that of  $RGO/MnO_2$  (366.6 F  $g^{-1}$ ), RGO/PANI (317.0 F  $g^{-1}$ ) and pristine RGO paper (27.5 F g<sup>-1</sup>). Moreover, this value is even larger than that of other MnO<sub>2</sub>/PANI/graphene ternary composites<sup>28,39,40</sup>. The results further confirm that the ternary composite exhibits superior electrochemical performance due to good synergistic effect between MnO2 nanoflakes and PANI nanorods and hierarchical assembly facilitating ion access into the composite interior. The changes of specific capacitance are also in consistent with the result of their CV tests. Rate capability is also crucial to evaluate the power performance of SCs, which can be determined by using GCD technique under various current densities. Fig. 7b depicts the rate performance of both composite electrodes. It is evident that the RGO/MnO<sub>2</sub>/PANI ternary composite yields significantly higher capacitance than RGO/MnO<sub>2</sub> binary composite during the whole current density range. The capacitance retention of the RGO/MnO<sub>2</sub>/PANI composite is 53.8% as current density increases from 1.0 to 50 A g<sup>-1</sup>, whereas that of RGO/MnO<sub>2</sub> and RGO/PANI is only 49.7% and 51.3% respectively under the same condition.

The higher capacitance and better rate capability of RGO/MnO<sub>2</sub>/PANI composite are ascribed to the advantages of its unique structure. First, the PANI nanorods embedded into the interlaced MnO2 nanoflakes not only increase the electroactive sites for a fast and reversible Faradaic reaction, but also create plenty of open spaces in the composite for easy penetration of the electrolyte into the electrode interior. Second, ultrathin MnO2 nanoflakes and PANI nanorods with small diameter can reduce the diffusion paths for electrons/ions and facilitate fast kinetics and high chargedischarge rates, ensuring the high utilization of MnO2 and PANI. Third, the MnO<sub>2</sub>/PANI hybrid nanostructures strongly adhere to the surface of RGO paper, avoiding the addition of conductive additives/polymer binder during the fabrication of electrodes, and thus enhancing the utilization of the electroactive material that contributes to the total capacitance and the rate capability 21. Furthermore, incorporation of nanometer-sized PANI into the composite increases the conductivity, reduces charge transfer resistance and enables fully ionic access, thus favoring higher capacitance. In addition, the RGO substrate serves as conductive paths to provide excellent interfacial contact for MnO<sub>2</sub>/PANI composite, and the strong synergistic effect between them also results in the enhanced electrochemical performance.

In order to clarify the transport characteristics of the charge carriers within the ternary composite paper electrode, electrochemical impedance spectroscopy (EIS) was employed. The Nyquist plots of RGO, RGO/PANI, RGO/MnO<sub>2</sub> and RGO/MnO<sub>2</sub>/PANI are given in Fig. 7c. In the low frequency region, all electrodes show a sloped line, indicating the

capacitive behavior. The straight line of RGO/MnO<sub>2</sub>/PANI composite electrode is more vertical compared with the other samples, implying its better capacitive performance due to a faster ionic diffusion rate of electrolyte ions into this ternary composite electrode 41. In the high frequency region (inset of Fig. 7c), the real axis intercept reflects the equivalent series resistance  $(R_e)$  which is related to intrinsic resistance of substrate, ionic resistance of electrolyte and contact resistance between the active material and current collector <sup>42</sup>. The value of  $R_e$  from the Nyquist plot is 2.48, 14.9, 5.30 and 4.40  $\Omega$  for RGO/MnO<sub>2</sub>/PANI, RGO/MnO<sub>2</sub>, RGO/PANI respectively. The lowest Re value of RGO/MnO<sub>2</sub>/PANI composite electrode reflects that the conductivity and electroactivity of the composite are remarkably enhanced after introduction of PANI nanorod networks. In addition, only RGO/MnO<sub>2</sub>/PANI composite electrode shows invisible semicircle, demonstrating a very low charge-transfer resistance  $(R_{ct})$  determined by the diameter of the semicircle in the high frequency region. Similar phenomenon can also be found for other PANI-based materials <sup>43,44</sup>. Hence, both the higher ionic diffusion rate and lower charge-transfer resistance give rise to enhanced specific capacitance of the RGO/MnO<sub>2</sub>/PANI composite.

Long-term cycling stability is another important aspect for evaluating the supercapacitor electrodes for practical applications. Fig. 7d illustrates the capacitance retention for RGO/MnO2/PANI composite electrode versus cycle number at the current density of 20 A g<sup>-1</sup>. The capacitance retention is slight over 100% during the first 500 cycles and then decreases gradually all the way, but still keeps 85% after 10<sup>4</sup> cycles. The increased capacitance in the beginning can be interpreted as a result of the electrochemical activation commonly encountered in electrochemistry process<sup>45</sup>. Additionally, the stable charge and discharge curves for the last 10 cycles (inset of Fig. 7d) also confirm a good electrochemical stability of RGO/MnO<sub>2</sub>/PANI composite electrode. The good stability comes from the synergistic effect between MnO<sub>2</sub>/PANI and RGO. The RGO paper acts as a robust substrate to immobilize active MnO<sub>2</sub>/PANI hybrid nanostructures and endows the structural integrity of hybrid composite on it, and therefore prevents the dissolution and loss of active materials due to the volume changes during the cycling process<sup>15</sup>. In addition, PANI nanorod networks formed between the MnO<sub>2</sub> nanoflakes also serve as a protection layer to keep MnO<sub>2</sub> from dissolution into the electrolyte. Thus, the free-standing RGO/MnO<sub>2</sub>/PANI composite paper with high capacitance, excellent rate capability and good cycling stability could be a promising electrode material for flexible SCs applications.

# Conclusions

Combining the efficient electro-deposition method and chemical oxidative polymerization, a flexible ternary composite of MnO<sub>2</sub> nanoflakes/PANI nanorods hybrid nanostructures on RGO paper has been successfully fabricated for binder-free supercapacitor electrode applications. Morphological and structural characterizations indicate the

Journal Name ARTICLE

embedding of interconnected PANI nanorods into interlaced  $MnO_2$  nanoflakes not only enhances the contact area between the active material and electrolyte but also facilitate the ions diffusion. The electrochemical analysis shows that the ternary composite material possesses large specific capacitance of 636.5 F g<sup>-1</sup> at 1.0 A g<sup>-1</sup> and excellent rate capacity (53.8% retention at 50 A g<sup>-1</sup>). In addition, the capacitance of RGO/MnO<sub>2</sub>/PANI can retain 85% of the original value after 10<sup>4</sup> cycles at 20 A g<sup>-1</sup>. The results provide a promising and effective way to develop high-performance flexible electrode materials for SCs.
