11 4
12
13 5 Based on the monoclonal antibodies against 3, 3', 5, 5'-tetraiodo-L-thyronine (T₄), a
14
15 6 competitive indirect chemiluminescence immunoassay (CLEIA) used for quantitative
16
17 7 determination of total T₄ in human serum was established. The relevant results indicated that
18
19 8 the determined coating antigen concentration was 2.7 μg mL⁻¹ and the CLEIA titer of ascites
20
21 9 was 1:8.0×10⁴. The standard curve was $y = -0.495x + 1.095$, with coefficient of
22
23 10 determination, $R^2 = 0.988$, and derived half inhibition concentration (IC₅₀) of T₄ was 16.0
24
25 11 ng mL⁻¹. The system detection limit was 9.23 ng mL⁻¹. The mean inter- and intra-assay
26
27 12 variations were 5.89 % and 4.02 %, respectively. The detected data of total T₄ in human
28
29 13 serum from seven patients with this method exhibited significant correlation with reported
30
31 14 clinical data, suggesting this CLEIA method could be applicable to clinical diagnosis of
32
33 15 thyroid gland disease.

1 Introduction

Thyroid dysfunction is common in general population and quite prevalent among people aged over 60 years.¹ The concentration of 3, 3', 5, 5'-tetraiodo-L-thyronine (T₄) is a useful parameter for thyroid function diagnosis in clinical. Under normal physiological conditions, approximately 99.95% of T₄, binding to some specific proteins (mainly thyroxine binding globulin), exist in compound form, the rest remain free.² Since free T₄ level is always susceptible to the amount of bound T₄, and its detection requires complicated procedure,³ the concentration of total T₄ in human serum is generally accepted as an index of thyroid dysfunction. When the concentration of total T₄ in human serum is out of the reference range, 46.62 ng mL⁻¹ to 140.64 ng mL⁻¹, thyroid gland is in abnormal state.

Currently, several immunoassay technologies for total T₄ detection are available. These include radioimmuno-assay (RIA), enzyme linked immunosorbent assay (ELISA), time resolved fluoroimmunoassay (TRFIA), high-performance liquid chromatography (HPLC), and electro-chemiluminescence immunoassay (ECLI). Although, RIA gives sensitive detection limit (5.0 ng mL⁻¹),⁴ the demand for isotopes restricts its application inevitably. Both ELISA and HPLC methods, using safer agents, yet exhibit poor sensitivity (about 13.83 ng mL⁻¹, and 0.10 µg mL⁻¹, respectively).^{5,6} TRFIA and ECLI can separately offer sensitivity at 5.36 mg mL⁻¹ and lower than 0.30 pmol L⁻¹ level,^{7,8} but sophisticated operations are only managed by specialized technicians.

A promising alternative to above-mentioned assays is chemiluminescence enzyme immunoassay (CLEIA). It owns safety, sensitivity, convenience and broad applicability.⁹⁻¹²

The quantitative analysis is achieved through substance binding to special antibody, further

1
2
3
4 45 triggering photons release. So far, CLEIA test has been mainly applied in diagnosis of small
5
6 46 cell lung carcinoma,⁹ squamous cell carcinoma,¹³ hepatocellular carcinoma,^{14, 15} etc., but
7
8
9 47 satisfactory CLEIA detection for thyroid dysfunction has not been reported. Hence, a
10
11 48 sensitive and convenient method, based on CLEIA, is urgent to the clinical diagnosis and life
12
13
14 49 science research.

15
16 50 Using developed monoclonal antibodies against T₄ (T₄ McAb)⁵ and specific polyclonal
17
18 51 antibodies conjugated with horseradish peroxidase (HRP), we established a competitive
19
20
21 52 indirect CLEIA. Methodology parameters of CLEIA were evaluated and optimized. It is
22
23
24 53 demonstrated that the optimized method satisfies clinical detection criteria, as the examined
25
26 54 concentrations of total T₄ in human serum samples are in accordance with the clinical data.
27
28

30 31 56 **2 Experimental**

32 33 57 **2.1 Chemicals and reagents**

34
35
36 58 3,3',5,5'-tetraiodo-L-thyronine (T₄) and horseradish peroxidase (HRP), coupled with goat
37
38
39 59 anti-mouse IgG were purchased from Sigma-Aldrich, USA. Dimethylsulfoxide (DMSO),
40
41
42 60 hydrogen peroxide (H₂O₂) and trihydroxy methyl aminomethane (Tris) were obtained from
43
44 61 Sinopharm Chemical Reagent Co., Ltd (SCRC). Luminol and *p*-iodophenol were purchased
45
46 62 from Alfa Aesar, USA.

47
48
49 63 T₄-BSA, T₄ McAb,⁵ CLEIA washing buffer, CLEIA coating buffer, blocking buffer
50
51 64 (1×PBST buffer containing 1% gelatin) and chemiluminescence substrate buffer were
52
53
54 65 prepared in our laboratory.
55
56
57 66

67 2.2 Serum samples

68 Patients' venous blood samples were supplied by Central Hospital of Nanhui District in
69 Shanghai.

71 2.3 Instrumentation

72 Synergy 2 SL Luminescence Microplate Reader (10 amol ATP in flash analysis system and
73 100 amol ATP in glow system), with Gen 5 Data Analysis Software, was employed for
74 photon signals capturing, multi-analyzing and data-processing. 75004261 centrifuge was
75 from Thermo Scientific, USA. 96-well chemiluminescence white microplates were purchased
76 from Greiner Bio-One, Germany.

78 2.4 Establishment of T₄ CLEIA

79 **2.4.1 Working concentration determination for coating antigen and T₄ McAb.** The
80 working concentrations of coating antigen and antibody are critical to sensitivity of
81 immunoassay. According to checkboard assay,¹⁶ with coating buffer, sequentially dilute
82 T₄-BSA (8.0 mg mL⁻¹) solution into 4.0 μg mL⁻¹, 2.7 μg mL⁻¹, 2.0 μg mL⁻¹, 1.6 μg mL⁻¹, 1.3
83 μg mL⁻¹ and 1.1 μg mL⁻¹, and then transfer 100 μL solution into 96-well chemiluminescence
84 microplate per well, and incubate for 4 h at 37 °C. Wash the microplate three times with
85 1×PBST buffer and add 200 μL 1% gelatin 1×PBST into each well to block. Then wash three
86 times again, and orderly add 100 μL T₄ McAb in dilution ratios (1:4.0×10⁴, 1:6.0×10⁴,
87 1:8.0×10⁴, 1:1.0×10⁵, 1:1.2×10⁵, 1:1.4×10⁵ and 1:1.6×10⁵) into the corresponding blocked
88 wells. Use 1×PBST buffer containing 1% gelatin as negative control. Here, we use 1×PBST

1
2
3
4 89 buffer that contains 5 % fetal bovine serum (FBS) and 0.05 % Tween-20 as antibody dilution
5
6 90 solution. FBS can restrain antibody from nonspecific absorption, and Tween-20 can remove
7
8 91 nonspecifically binding antibody and enhance washing effect. Incubate the microplate for 1.5
9
10 92 h at 37 °C. Then, wash the plate three times and add 100 µL goat anti-mouse IgG-HRP
11
12 93 (1:4.0×10³ dilution) to each well. After that, add 1006.225 µL reaction solution (1.0 mL
13
14 94 chemiluminescence substrate buffer, 0.625 µL *p*-iodophenol, 4.0 µL Luminol and 1.6 µL
15
16 95 H₂O₂) per well, and detect instantaneous chemiluminescence signals, defined as counting
17
18 96 photon per second (CPS), within 5 minutes.
19
20
21
22
23
24
25

26 98 **2.4.2 Establishment of T₄ competitive indirect CLEIA.** In order to avoid the
27
28 99 interference of endogenous T₄ in FBS, we use 1×PBST complemented with 1% gelatin
29
30 100 instead of 5% FBS to dilute the antibody. With 1% DMSO 1×PBS, prepare 2.0 ng mL⁻¹, 10
31
32 101 ng mL⁻¹, 20 ng mL⁻¹, 40 ng mL⁻¹, 80 ng mL⁻¹, 120 ng mL⁻¹, 160 ng mL⁻¹ and 200 ng mL⁻¹ T₄
33
34 102 standard solution. According to the procedure in 2.4.1, use coating antigen and T₄ McAb at
35
36 103 working concentration, respectively, and replace 100 µL T₄ McAb solution with the mixture
37
38 104 of 50 µL T₄ standard solution and 50 µL T₄ McAb solution. The inhibitory effect of different
39
40 105 T₄ standard concentrations is expressed as percent inhibition (B/B_0) according to the
41
42 106 formula:
43
44
45
46
47
48

$$49 \quad (B/B_0)\% = (B/B_0) \times 100\%$$

50
51 108 Where, B_0 = CPS in well containing no T₄, B = CPS in well containing T₄. Accordingly,
52
53 109 establish plot T₄ standard curve, where x axis represents \log_{10} of standard T₄ concentration
54
55 110 while y axis stands for relative luminous intensity (B/B_0). Calculate IC₅₀ value, according
56
57
58
59
60

1
2
3
4 111 to the equation of the standard curve.¹⁷

5
6 112

7
8
9 113 **2.4.3 System detection limit.** The limit value of EIA, which represents detecting
10
11 114 sensitivity, has to be as low as possible. The CPS values of 16 blank controls, where,
12
13 115 physiological saline instead of T₄ standard solution, are measured by CLEIA method. The
14
15 116 mean value (\bar{X}) and standard deviation (SD) are statistically analyzed. On this basis,
16
17 117 calculate the value of “ $\bar{X}-3SD$ ”. By introducing the calculated values into the established
18
19 118 equation of the standard curve, the corresponding T₄ concentration will be obtained, which is
20
21 119 defined as the detectable limit that indicates sensitivity of immunoassay.¹⁸
22
23
24
25

26 120

27
28
29 121 **2.4.4 Precision and accuracy.** Precision is expressed as inter- and intra- coefficient of
30
31 122 variation (CV%), which are required to be lower than 10% and 5.0% separately in
32
33 123 immunoassay. Intra- and inter-assay variations of competitive CLEIA assay for T₄ standard
34
35 124 solution in 2.4.2 are analyzed with five replicates on the strength of the formula:

36
37
38 125
$$CV\% = SD / [1.414 \times (B / B_0)] \times 100\%$$

39
40
41 126

42
43
44 127 **2.5 Sample volume determination**

45
46 128 To determine the suitable serum volume for T₄ detection, different volumes (20 μL, 30 μL, 35
47
48 129 μL, 40 μL) are used in CLEIA method. Then, the relative difference between examined data
49
50 130 and clinical data is assessed.
51

52
53
54 131

55
56 132 **2.6 Applicability of T₄ CLEIA**

1
2
3
4 133 With optimized sample volume, T₄ concentrations in serum samples from seven patients are
5
6 134 detected by the established method in 2.4.2 to evaluate analytical accuracy. The correlation
7
8
9 135 between tested data and clinical data is determined through the plotted graph, where *x* axis
10
11 136 represents reported data clinically and *y* axis indicates detected data.

137 **2.7 Statistical analysis**

138 The quantitative data of three to five repetitions are expressed as averages ± SD. Statistical
139 significance is assessed with Student's *t*-test, when *P* > 0.05, suggesting no significant
140 difference.

142 **3 Results and Discussion**

143 **3.1 Establishment of T₄ CLEIA**

144 **3.1.1 Working concentration determination for coating antigen and T₄ McAb.** The
145 determined working concentrations of coating antigen (T₄-BSA) and T₄ McAb were shown in
146 Table 1. When the dilution ratio of T₄ McAb kept constant, CPS obviously reduced with
147 decreasing concentration of T₄-BSA; On the other hand, when the concentration of T₄-BSA
148 kept fixed, the CPS diminished with the increasing dilution ratio of T₄ McAb. When the
149 96-well microtiter plate, coated with 2.7 μg mL⁻¹ T₄-BSA, was applied with 1:8.0×10⁴
150 dilution of T₄ McAb, the CPS value was 101924, most approximate to 1.0×10⁵. Therefore,
151 the appropriate coating antigen concentration in CLEIA was determined as 2.7 μg mL⁻¹, and
152 the working dilution of T₄ McAb, 1:8.0×10⁴.

153 **Table 1** Working concentration determination for coating antigen and T₄ McAb

154

1
2
3
4 155 **3.1.2 Confirmation of T₄ CLEIA.** Based on the optimized CLEIA assay and data
5
6 156 acquired from 2.4.2, a standard curve for T₄ was obtained, showed in Fig. 1. The regression
7
8 157 equation was $y = -0.495x + 1.095$ with coefficient of determination, $R^2 = 0.988$. The
9
10 158 derived IC₅₀ for T₄ was 16.0 ng mL⁻¹, slightly lower than that reported with time-resolved
11
12 159 immunofluorometric assay by Tan Yuhua⁷ and 54.4% lower than that with competitive
13
14 160 indirect ELISA (ciELISA) we established.⁵ Excellent linear correlation existed between the
15
16 161 relative luminous intensity (B/B_0) and \log_{10} of standard T₄ concentration. The working
17
18 162 range of this assay was determined from 2.0 ng mL⁻¹ to 200 ng mL⁻¹.

19
20
21 163 **Fig.1** The standard curve for T₄ obtained with the established CLEIA (Triplings per
22
23 164 point).

24
25
26 165
27
28 166 **3.1.3 System detection limit.** According to T₄ CLEIA standard curve, the CPS values of
29
30 167 16 blank samples (Table S1) were used to calculate the value of $\bar{X} - 3SD$. The assay
31
32 168 sensitivity of system detection limit was shown to be 9.23 ng mL⁻¹, generally similar to those
33
34 169 reported so far.^{4,19}

35
36
37 170 **Table S1** CPS values of 16 blank standard samples with CLEIA method
38
39

40
41
42 171
43
44 172 **3.1.4 Precision and accuracy.** As shown in Table 2, the mean intra- and inter- assay
45
46 173 variations were 4.02 % (< 5.0 %) and 5.89 % (< 10 %), respectively, demonstrating this
47
48 174 CLEIA possessed high accuracy.

49
50
51 175 **Table 2** The mean intra- and inter- assay variations of CLEIA
52
53

54
55 176

56
57
58 177 **3.2 Sample Volume determination.**

1
2
3
4 178 As listed in Table 3, when 30 μL sample volume was taken, the relative difference between
5
6 179 detected data and reported clinical data of human serum samples exhibited minimum,
7
8
9 180 suggesting that 30 μL was the most appropriate volume for detection.

10
11 181 Furthermore, significant difference among different sample volumes of human sera was
12
13 182 analyzed with Least Significant Difference (LSD) method (Table S2), and mean coefficient
14
15 183 variation of 30 μL was quite significantly different from those of 35 μL and 40 μL , but not
16
17
18 184 from those of 20 μL . Consequently, sample volume from 20 μL to 30 μL could be used in
19
20
21 185 CLEIA.

22
23
24 186 **Table 3** Total T_4 concentrations in serum samples from three patients with CLEIA method

25
26 187 **Table S2** Significant difference among four mean coefficient of variations in Table 3 using
27
28
29 188 Least Significant Difference (LSD) (Letter notation)

30
31 189

32 33 34 190 **3.3 Applicability of T_4 CLEIA.**

35
36 191 The correlation between T_4 concentrations detected with CLEIA and those clinically reported
37
38 192 in the same seven patients' sera was appraised in Fig. 2. The regression equation was
39
40 193 $y = 1.003x - 1.357$, with coefficient of determination, $R^2 = 0.918$, indicating good linear
41
42
43 194 correlation. Hence, this CLEIA method could satisfy clinical detection criteria.

44
45
46 195 Besides, according to data examined with CLEIA, T_4 concentration in one of human serum
47
48 196 samples, was 37.28 ng mL^{-1} , out of the normal reference value range (46.62 ng mL^{-1} to
49
50
51 197 140.64 ng mL^{-1}), suggesting the serum-owner's thyroid dysfunctioned.

52
53
54 198 **Fig.2** Correlation between detected data with CLEIA and reported clinical data (Tripletions
55
56 199 per point of detected data).

200

201 4 Conclusions

202 In this study, we established a competitive indirect CLEIA method to detect total T₄ in human
203 serum. Meanwhile, we also confirmed methodology parameters of this method, including
204 IC₅₀, linear detecting range, system detection limit, inter-assay and intra-assay variation.
205 Concretely, IC₅₀ of this CLEIA was 16.0 ng mL⁻¹. The linear detecting range was 2.0 ng mL⁻¹
206 to 200 ng mL⁻¹, and the limit value was 9.23 ng mL⁻¹. The method we established gave low
207 inter-assay variation (5.89%) and intra-assay variation (4.02%). All results above suggested
208 that we have established a highly-specific and excellently-sensitive T₄ examination system.

Table 1 Working concentration determination for coating antigen and T₄ McAb

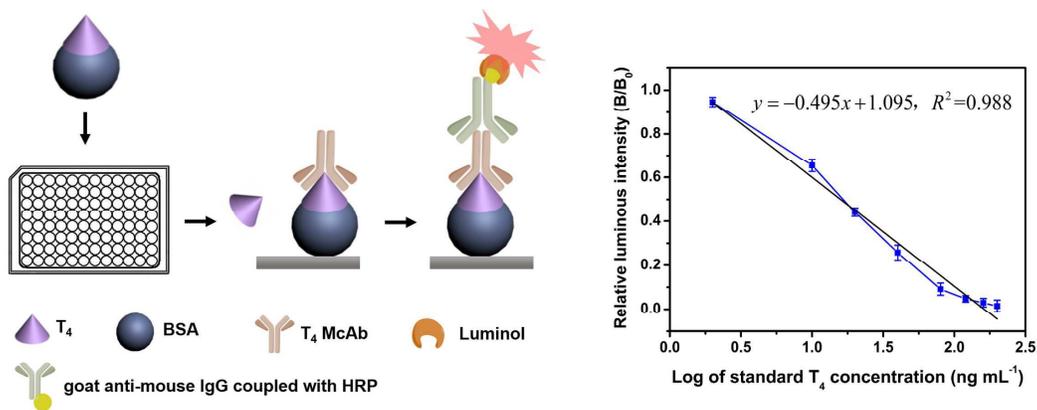

Coating antigen concentration ($\mu\text{g mL}^{-1}$)	T ₄ McAb dilution ($\times 10^4$)							
	1:4.0	1:6.0	1:8.0	1:10	1:12	1:14	1:16	0
4.0	214997	175135	154967	140972	118175	114054	84432	449
2.7	156973	125830	101924	93210	73698	75280	49545	302
2.0	127560	104857	72649	78028	57100	59605	38530	127
1.6	67306	59155	35763	36122	25819	28450	18888	213
1.3	67943	51360	44246	37774	29363	24726	18878	418
1.1	42680	34183	24667	21981	16281	16170	11503	628

Table 2 The mean intra- and inter- assay variations of CLEIA

Standard T ₄ concentration (ng mL^{-1})	Intra- replication	Intra- (B/B0) \pm SD	Inter- replication	Inter- (B/B0) \pm SD	CV%	
					Intra-	Inter-
200	5	0.0088 \pm 0.0000	5	0.0161 \pm 0.0000	0.00	0.00
160	5	0.0311 \pm 0.0000	5	0.0427 \pm 0.0050	0.00	8.28
120	5	0.1450 \pm 0.0141	5	0.1462 \pm 0.0250	6.88	12.1
80	5	0.3658 \pm 0.0312	5	0.3387 \pm 0.0477	6.03	9.96
40	5	0.6587 \pm 0.0304	5	0.7217 \pm 0.0915	3.26	8.97
20	5	0.8314 \pm 0.0529	5	0.9250 \pm 0.0335	4.50	2.56
10	5	0.9036 \pm 0.0194	5	0.9869 \pm 0.0255	1.52	1.83
2	5	0.9531 \pm 0.0085	5	0.9954 \pm 0.0172	0.89	1.73
mean		0.4872 \pm 0.0196		0.5216 \pm 0.0307	4.02	5.89

Table 3 Total T₄ concentrations in serum samples from three patients with CLEIA method

Sample Volume (μL)	Sample 1			Sample 2			Sample 3			Mean relative difference
	Detected data	Reported data	Relative difference	Detected data	Reported data	Relative difference	Detected data	Reported data	Relative difference	
20	91.97	106.68	13.79%	82.25	77.08	6.71%	46.42	57.07	18.67%	13.06%
30	108.23	106.68	1.45%	86.97	77.08	12.83%	53.37	57.07	6.48%	6.92%
35	132.19	106.68	23.91%	98.61	77.08	27.93%	65.79	57.07	15.28%	22.37%
40	127.37	106.68	19.39%	95.45	77.08	23.83%	65.18	57.07	14.21%	19.14%

Detection of T₄ by the established CLEIA method.
