## COMMUNICATION

## Difluoromethane as Precursor to Difluoromethyl Borates

Jacob B. Geri,<sup>[a]</sup> Ellen Y. Aguilera,<sup>[b]</sup> Nathaniel K. Szymczak<sup>[b]\*</sup>Received 00th January 20xx,  
Accepted 00th January 20xx

DOI: 10.1039/x0xx00000x

Difluoromethane ( $\text{CF}_2\text{H}_2$ ) is an ecologically-friendly refrigerant which holds promise as a source of  $\text{CF}_2\text{H}^-$ . However, its weak acidity ( $\text{p}K_{\text{a}} = 35\text{--}41$ ) and low stability of the conjugate base has prevented its utilization as a chemical feedstock. In this manuscript, we use a Lewis pair approach to deprotonate  $\text{CF}_2\text{H}_2$  and capture  $\text{CF}_2\text{H}^-$  as  $\text{R}_3\text{B}\text{-CF}_2\text{H}^-$  adducts. One reagent can be used as a base-free Suzuki reagent in palladium-mediated difluoromethylation, where  $\text{CF}_2\text{H}^-$  transfer is templated by precoordination to an azaborine derived  $\text{R}_3\text{B}\text{-CF}_2\text{H}^-$  reagent.

When incorporated into biologically active molecules, the difluoromethyl group acts as a metabolically stable lipophilic bioisostere of OH or SH groups.<sup>1–3</sup> As a result of these desirable properties, molecules containing  $-\text{CF}_2\text{H}$  groups are routinely investigated in drug development.<sup>4–6</sup> Many of the commonly used  $\text{CF}_2\text{H}$  transfer reagents (such as  $\text{SiMe}_3\text{CF}_2\text{H}$  and  $\text{Zn}(\text{CF}_2\text{H})_2$ ) are prepared from halofluoromethanes ( $\text{XCF}_2\text{H}$ ;  $\text{X} = \text{Cl}, \text{Br}, \text{F}$ ) and their derivatives,<sup>7–12</sup> compounds with high ozone depleting potential.<sup>13</sup> In contrast, difluoromethane ( $\text{CF}_2\text{H}_2$ ) would represent an attractive source of the difluoromethyl group if it could be deprotonated to reveal nucleophilic  $\text{CF}_2\text{H}^-$  fragments. It is nontoxic, has no ozone-depleting potential, and is already manufactured on a large scale as a refrigerant.<sup>14</sup> However, no approaches for nucleophilic difluoromethylation from difluoromethane have been reported.

Despite the attractive properties of  $\text{CF}_2\text{H}_2$  as a source of  $\text{CF}_2\text{H}^-$ , challenges associated with deprotonation and capture have prevented its use as a chemical synthon. In addition to low acidity (gas phase proton affinity: 389 kcal/mol;<sup>15</sup>  $\text{HCF}_3$ : 376 kcal/mol),<sup>16</sup> free  $\text{CF}_2\text{H}^-$  is unstable to  $\alpha$ -fluoride elimination.<sup>17</sup>

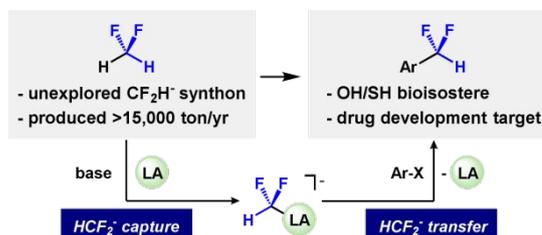

Figure 1. Conceptual outline of Lewis acid/base strategy to enable  $\text{CF}_2\text{H}^-$  capture/transfer from  $\text{H}_2\text{CF}_2$ .

Furthermore, if  $\text{CF}_2\text{H}^-$  is generated in the presence of a fluorophilic cation such as  $\text{Li}^+$ , immediate defluorination occurs.<sup>17</sup> If the  $\text{Li}$  is replaced with  $[\text{Cs}(18\text{-crown-}6)]^+$ , a cation with low  $\text{F}^-$  affinity, the corresponding  $[\text{CF}_2\text{H}]^-$  is highly basic and readily deprotonates THF. For these reasons,  $\text{CF}_2\text{H}_2$  has not been used to prepare synthetically useful  $\text{CF}_2\text{H}^-$  equivalents. These problems may be mitigated by deprotonating  $\text{CF}_2\text{H}_2$  in the presence of a Lewis acid (LA) that can capture  $\text{CF}_2\text{H}^-$  as a  $\text{LA}\text{-CF}_2\text{H}^-$  adduct, and then later release  $\text{CF}_2\text{H}^-$  in a subsequent reaction. To realize this strategy, selection of an appropriate Brønsted base and Lewis acid is critical, because the Lewis acid and base must be strong enough to deprotonate  $\text{CF}_2\text{H}_2$  and to stabilize  $\text{CF}_2\text{H}^-$  while also avoiding the formation of *inert* acid-base adducts.<sup>18</sup> We previously described a compatible Lewis acid / base approach that can resolve categorically similar issues with  $\text{ArCF}_2\text{H}$  substrates;<sup>19</sup> the acid/base partners mediate  $\text{CF}_2\text{Ph}^-$  generation, capture, and release. In this communication, we report the direct synthesis of  $\text{R}_3\text{B}\text{-CF}_2\text{H}^-$  adducts from difluoromethane and their ability to serve as nucleophilic sources of  $\text{CF}_2\text{H}^-$ .

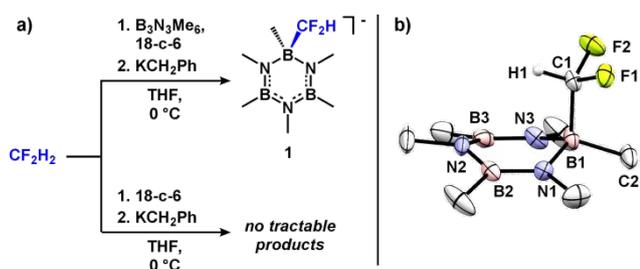

We hypothesized that an appropriate Lewis pair for difluoromethane deprotonation /  $\text{CF}_2\text{H}^-$  capture must satisfy several key criteria. The base must be sufficiently strong to deprotonate  $\text{CF}_2\text{H}_2$  and not contain fluorophilic cations such as  $\text{Li}^+$  and  $\text{Na}^+$ . The Lewis acid must be sufficiently strong to stabilize  $\text{CF}_2\text{H}^-$  against  $\alpha$ -fluoride elimination but weak enough

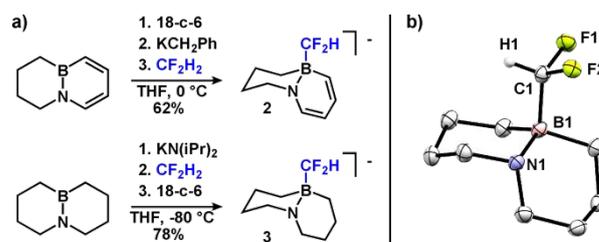

**Figure 2.** a) Synthesis of **1** from  $\text{H}_2\text{CF}_2$ . b) X-Ray crystal structure of **1**.  $\text{K}(18\text{-c-}6)(\text{THF})^+$  counterion omitted for clarity.

to release  $\text{CF}_2\text{H}^-$  nucleophiles. In addition to these requirements, the Lewis acid / base pairs must not quench their respective reactivity through the formation of irreversible adducts.<sup>18</sup> We selected  $\text{KCH}_2\text{Ph}$  as an initial base for experimental evaluation because of its high basicity ( $\text{p}K_a = 42$  (DMSO)),<sup>20</sup> straightforward preparation,<sup>21</sup> and potassium counteraction. Hexamethylborazine ( $\text{B}_3\text{N}_3\text{Me}_6$ ) was selected as the initial Lewis acid partner because it forms a reversible adduct with  $\text{KCH}_2\text{Ph}$  and is known to stabilize fluoroalkyl nucleophiles ( $\text{CF}_3^-$  and  $\text{CF}_2\text{Ar}^-$ ).<sup>19, 22, 23</sup>

When  $\text{CH}_2\text{F}_2$  gas was added to a deep red THF solution containing a 1:1:1 ratio of  $\text{KCH}_2\text{Ph}$ ,  $\text{B}_3\text{N}_3\text{Me}_6$ , and 18-crown-6 at  $0^\circ\text{C}$ , the solution became colorless after 90 minutes.  $^{19}\text{F}$  NMR spectroscopy revealed the formation of a new species at  $-128.23$  ppm exhibiting  $^2J_{11\text{B}-19\text{F}}$  and  $^1J_{1\text{H}-19\text{F}}$  coupling (32, 49 Hz) consistent with a  $\text{B}-\text{CF}_2\text{H}$  unit.<sup>24</sup> Trituration with pentane afforded a white solid in 95% yield, which was characterized by  $^1\text{H}$ ,  $^{11}\text{B}$ ,  $^{13}\text{C}$ , and  $^{19}\text{F}$  NMR spectroscopy. The  $^1\text{H}$  NMR spectrum revealed loss of symmetry of the  $\text{B}_3\text{N}_3\text{Me}_6$  unit with four  $-\text{CH}_3$  resonances (2.51, 2.49, 0.05,  $-0.39$  ppm), as well as a new  $-\text{CF}_2\text{H}$  resonance at 5.20 ppm with  $^1J_{1\text{H}-19\text{F}}$  coupling (51 Hz). The  $^{11}\text{B}$ -NMR spectrum revealed one broad (32.3 ppm) and one sharp resonance ( $-5.7$  ppm) integrating in a 2:1 ratio. These data are consistent with a dearomatized  $\text{B}_3\text{N}_3\text{Me}_6$  unit containing one tetrahedral and two planar boron atoms, enabling assignment of the isolated compound as  $\text{K}(18\text{-crown-}6)\text{B}_3\text{N}_3\text{Me}_6(\text{CF}_2\text{H})$  (**1**). Importantly, in the absence of  $\text{B}_3\text{N}_3\text{Me}_6$ , no tractable reaction products are observed.

Crystals suitable for X-Ray diffraction were obtained by allowing pentane to diffuse into a concentrated solution of **1** in THF at  $-35^\circ\text{C}$ . The solid-state structure revealed a  $\text{CF}_2\text{H}^-$  anion coordinated to a dearomatized  $\text{B}_3\text{N}_3\text{Me}_6$  unit, capped with a  $\text{K}(18\text{-crown-}6)^+$  cation (Figure 2b). The  $\text{B}-\text{CF}_2\text{H}$  bond is elongated relative to the other  $\text{B}-\text{CH}_3$  bonds (1.640(5) vs 1.621(5), 1.612(7), 1.594(7) Å), consistent with lower bond strength (*vide infra*). The structure is largely homologous with other fluoroalkyl-borazine adducts  $\text{K}(18\text{-crown-}6)\text{B}_3\text{N}_3\text{Me}_6(\text{CF}_3)$  and  $\text{K}(18\text{-crown-}6)\text{B}_3\text{N}_3\text{Me}_6(\text{CF}_2\text{Ph})$ , which also exhibit elongated  $\text{B}-\text{C}$  distances of 1.656(4) and 1.670(6) Å.<sup>19, 22</sup>

**1** is the first reported  $\text{R}_3\text{B}-\text{CF}_2\text{H}^-$  adduct.<sup>25</sup> Organoboron-ate complexes of this type are the active form of commonly used Suzuki reagents in palladium-catalyzed cross coupling, and the known ability of  $\text{K}(18\text{-crown-}6)\text{B}_3\text{N}_3\text{Me}_6(\text{CF}_3)$  and  $\text{K}(18\text{-crown-}6)\text{B}_3\text{N}_3\text{Me}_6(\text{CF}_2\text{Ph})$  to transfer fluoroalkyl anions to Pd(II) centers

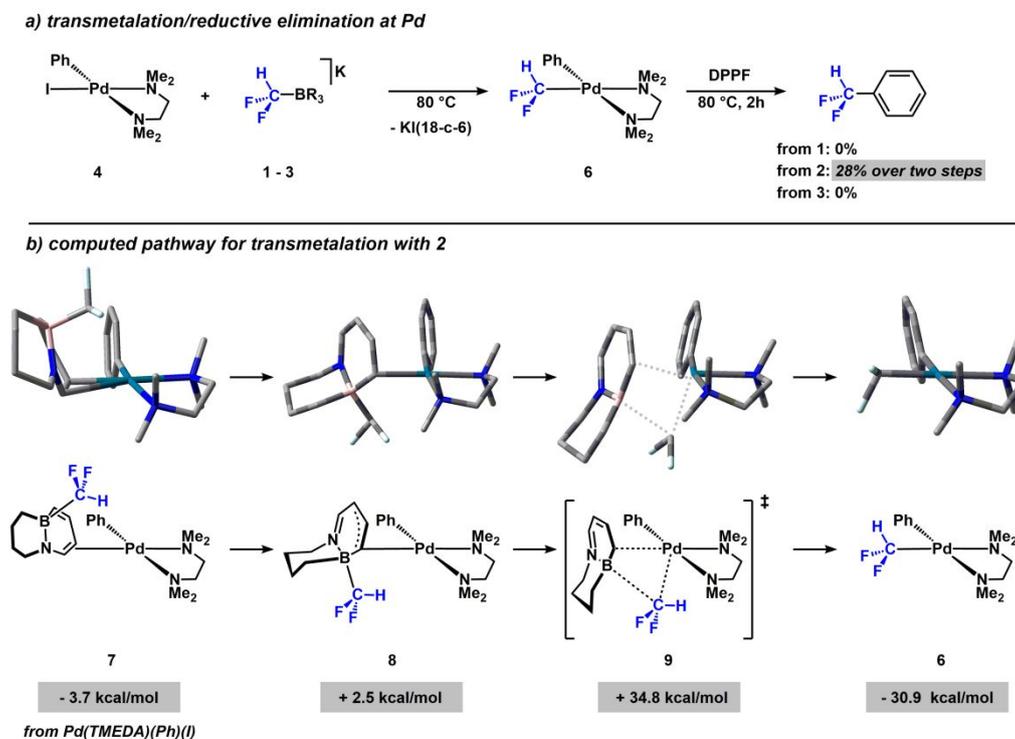

**Figure 3.** a) Synthesis of **2** and **3** from  $\text{CF}_2\text{H}_2$ . b) X-Ray structure of **3**.  $\text{K}(18\text{-c-}6)(\text{THF})$  counterion omitted for clarity.

such as  $\text{Pd}(\text{TMEDA})(\text{Ph})\text{I}$  (TMEDA = tetramethylethylenediamine) suggested that **1** may be able to promote similar reactivity. Unfortunately, **1** did not react with  $\text{Pd}(\text{TMEDA})(\text{Ph})\text{I}$  even under forcing conditions (24 h,  $80^\circ\text{C}$  in THF). The lack of reactivity and shorter  $\text{B}-\text{CF}_2\text{H}$  bond relative to analogous  $-\text{CF}_3^-$  and  $\text{CF}_2\text{Ph}^-$  adducts alluded to a stronger  $\text{B}-\text{CF}_2\text{H}$  bond preventing  $\text{CF}_2\text{H}$  transfer. We confirmed this hypothesis *in silico* and found that the calculated affinity of  $\text{B}_3\text{N}_3\text{Me}_6$  for  $\text{CF}_2\text{H}^-$  ( $-33$  kcal/mol) was 10 kcal higher than for  $\text{CF}_3^-$  ( $-23$  kcal/mol) at the M062X/6-31g(d,p) level of theory.

One option to lower the kinetic barrier to  $\text{CF}_2\text{H}$  transfer is *via* pre-coordination to an adjacent ligand donor group. To implement this design principle for  $\text{CF}_2\text{H}^-$  transfer, we targeted two [6,6]-fused 1,2-azaborine rings that either contain (1,2,3,4-tetrahydro-[1,2]azaborinino[1,2-a][1,2]azaborinine)<sup>26</sup> or omit (octahydro-[1,2]azaborinino[1,2-a][1,2]azaborinine)<sup>27</sup> a nucleophilic  $\pi$ -system. Their calculated  $\text{CF}_2\text{H}^-$  affinity (M062X/6-31g(d,p)) is similar to  $\text{B}_3\text{N}_3\text{Me}_6$  ( $-33$  (**2**) and  $-34$  (**3**) vs.  $-33$  (**1**) kcal/mol) making these adducts suitable candidates to test our hypothesis. Adducts between these Lewis acids and  $\text{CF}_2\text{H}^-$  would present nucleophilic  $-\text{C}$  and/or  $-\text{N}$  nucleophilic sites proximal to the  $\text{CF}_2\text{H}^-$  group, and could serve to direct  $\text{CF}_2\text{H}^-$  transfer. When a solution of either of the [6,6]-fused 1,2-azaborine Lewis acids,  $\text{KCH}_2\text{Ph}$ , and 18-crown-6 was treated with  $\text{CH}_2\text{F}_2$ ,  $\text{CF}_2\text{H}^-$  adducts analogous to **1** ( $\text{K}(18\text{-crown-}6)(\text{2: } 1,2,3,4\text{-tetrahydro-[1,2]azaborinino[1,2-a][1,2]azaborinine})(\text{CF}_2\text{H})$ ; **3**:  $\text{K}(18\text{-crown-}6)(\text{octahydro-[1,2]azaborinino[1,2-a][1,2]azaborinine})(\text{CF}_2\text{H})$ ) were obtained as solids in 62% and 34% yield. The yield of **3** was increased to 78% by substituting bulky  $\text{KN}(\text{iPr})_2$ <sup>28</sup> for  $\text{KCH}_2\text{Ph}$ .

$^{19}\text{F}$ -NMR spectra of **2** exhibited two resonances ( $-127.10$  and  $131.96$  ppm) with  $^2J_{19\text{F}-19\text{F}}$ ,  $^1J_{1\text{H}-19\text{F}}$ , and  $^2J_{11\text{B}-19\text{F}}$  coupling (311, 54, and 20 Hz), while the  $^{11}\text{B}$ -NMR spectrum showed a sharp peak at  $-10.22$  ppm. These data are consistent with a  $\text{B}-\text{CF}_2\text{H}$  unit containing diastereotopic fluorine units. **3** exhibited a single  $^{19}\text{F}$  resonance (127.04 ppm,  $^1J_{1\text{H}-19\text{F}}$ ,  $^2J_{11\text{B}-19\text{F}} = 51$  and 18 Hz), a sharp  $^{11}\text{B}$ -NMR resonance at  $-12.4$  ppm, and  $\text{C}_2$ -symmetric  $^1\text{H}$  and  $^{13}\text{C}$  NMR resonances. A single crystal of **3** was grown by allowing pentane to diffuse into a THF solution at  $-35^\circ\text{C}$ , and the solid state structure revealed that **3** exhibits a bent geometry of the azaborine unit, similar to that of the hydrocarbon decalin, capped by a  $\text{B}-\text{CF}_2\text{H}$  group. The  $\text{B}-\text{CF}_2\text{H}$  bond in **3** (1.633(3) Å) is within error of that in **1** (1.640(5) Å), and is consistent with their similar calculated  $\text{CF}_2\text{H}^-$  affinities and  $\text{B}-\text{CF}_2\text{H}$  bond lengths (1.633 and 1.638 Å).

## COMMUNICATION

**Figure 4.** a) Transmetalation of **1-3** to Pd(TMEDA)(Ph)I and subsequent reaction with 1,1'-bis(diphenylphosphino)ferrocene (DPPF). b) Computed pathway for transmetalation using **2** (M06L2X/6-31g(d,p)). Hydrogen atoms omitted for clarity.

To assess whether pre-coordination could provide a more kinetically accessible pathway for  $\text{CF}_2\text{H}^-$  transmetalation, we evaluated the reactivity of **2** and **3** with Pd(TMEDA)(Ph)I. Heating a mixture of **2** and 1.5 equivalents Pd(TMEDA)(Ph)I (**4**) at 80 °C afforded a 1:1 ratio of Pd(TMEDA)( $\text{CF}_2\text{H}$ )<sub>2</sub> (**5**)<sup>29</sup> and Pd(TMEDA)( $\text{CF}_2\text{H}$ )(Ph) (**6**)<sup>30</sup> in 55% combined yield as identified by <sup>19</sup>F-NMR spectroscopy. Addition of two equiv. DPPF, followed by heating to 80 °C for 2 h triggered reductive elimination of difluoromethylbenzene in 28% combined yield over both steps.<sup>31</sup> In contrast, **3** or **1**, which do not contain a nucleophilic  $\pi$ -system, afforded Pd(TMEDA)( $\text{CF}_2\text{H}$ )<sub>2</sub> in only trace quantities; further reaction with DPPF did not yield Ph $\text{CF}_2\text{H}$ .

These experiments highlight ring unsaturation as a key structural element that can be used to direct  $\text{CF}_2\text{H}^-$  transfer and suggests that precoordination of the  $\text{R}_3\text{B-CF}_2\text{H}^-$  adduct may facilitate transmetalation. We assessed this hypothesis using a combined experimental / theoretical approach. Combination of **2** and **4** at 25 °C afforded a deep red species (**7**) with new NMR resonances. Titration of **2** with **4** identified **7** as a 1:1 adduct of **2** and **4**. Alternative reagents **3** and **1**, which lack a nucleophilic  $\pi$ -system, did not form observable adducts when combined with **4**. Heating **7** at 80 °C for 2 hours afforded

Pd(TMEDA)( $\text{CF}_2\text{H}$ )(Ph) (**6**), establishing **7** as an intermediate formed prior to  $\text{CF}_2\text{H}^-$  transfer. <sup>1</sup>H-<sup>1</sup>H COSY and <sup>1</sup>H-<sup>13</sup>C HSQC spectra allowed a partial structural assignment for **7**. Notably, <sup>1</sup>H-NMR resonances associated with the  $\text{sp}^2$  C-H groups in the azaborine fragment (C1-H: 4.89, C2-H: 4.85, C3-H: 4.07, C4-H: 7.86) are significantly shifted with respect to those found in unbound **2**, suggesting a Pd- $\pi$  interaction in **7**. To augment the assignment, DFT analyses were used to identify two structural isomers of **7** as energetic minima, in which the closest Pd-C contact is at either the C3 or C1 position. Of these two isomers, the isomer with Pd-C3 coordination was more stable by -1.3 kcal/mol and the calculated NMR shifts<sup>32</sup> more closely resembled the experimental values ((C1-C4)-H: 5.40, 5.01, 3.15, 8.20 vs. 2.58, 7.63, 5.29, 6.26), allowing us to assign the connectivity of **7** as depicted in Figure 4.

An associative mechanism for  $\text{CF}_2\text{H}^-$  transmetalation from **2** to **4** via **7** was then computationally evaluated (M06L2X/6-31g(d,p)). In the first step, I<sup>-</sup> is displaced by **2** to form the observed prereactive complex **7** in an exothermic process (-3.8 kcal/mol). Rotation of the ring positions the  $\text{CF}_2\text{H}^-$  group in close proximity to the Pd(II) center (**8**: +1.3 kcal/mol).  $\text{CF}_2\text{H}^-$  transfer occurs through  $\beta$ -alkyl elimination (transition state **9**) to form

product **6** and the free azaborine Lewis acid with a net barrier of 34.7 kcal/mol. These computational and experimental data support our hypothesis that an associative mechanism for CF<sub>2</sub>H<sup>-</sup> transmetalation to Pd(II) is operative for reagent **2**.

In conclusion, we have developed the first strategy to repurpose CF<sub>2</sub>H<sub>2</sub>, widely available refrigerant, into a –CF<sub>2</sub>H<sup>-</sup> building block. A compatible Lewis acid/base pair approach enabled the preparation of a family of three boron-CF<sub>2</sub>H<sup>-</sup> adducts (**1-3**) following difluoromethane deprotonation. Of these reagents, only **2** can transmetalate CF<sub>2</sub>H<sup>-</sup> to palladium(II), a challenging transformation which has not been demonstrated using B-CF<sub>2</sub>H<sup>-</sup> sources.<sup>29, 30, 33, 34</sup> We identified that templated coordination through the π-system of **2** is required to facilitate –CF<sub>2</sub>H<sup>-</sup> transfer, and used the resulting difluoromethylpalladium complex to prepare PhCF<sub>2</sub>H. We anticipate that this conceptual approach to difluoromethane activation and transfer may be applied to other reactive nucleophiles and that difluoromethylborate adducts will find applications in organic synthesis through further optimization.

### Acknowledgments

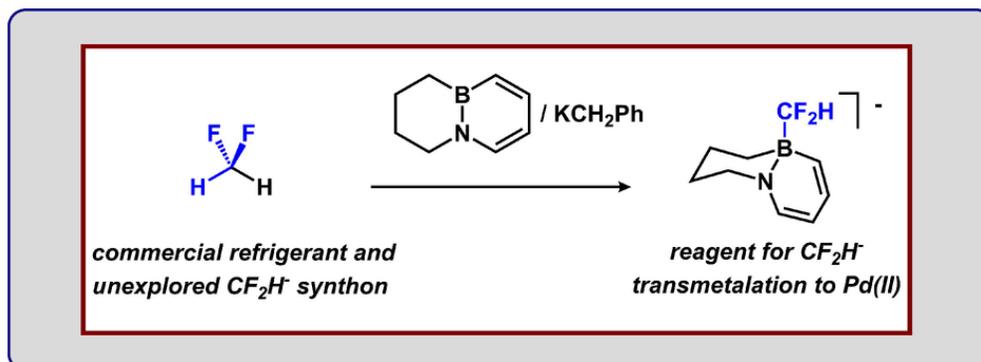

This work was supported by the University of Michigan Department of Chemistry, a Rackham Predoctoral Fellowship (JBG), and an NSF CAREER (grant CHE-1350877). X-ray diffractometers used were funded by the NSF (CHE 1625543). N.K.S. is a Camille Dreyfus Teacher-Scholar. We thank Dr. Jeff Kampf for crystallographic assistance, and Prof. Arthur Ashe for helpful discussions regarding the synthesis of 1,2,3,4-tetrahydro-[1,2]azaborinino[1,2-a][1,2]azaborinine and octahydro-[1,2]azaborinino[1,2-a][1,2]azaborinine.

### Conflicts of interest

We have submitted a patent application regarding chemistry similar to that described in this work.
