Described is an approach to preparing the first iClick network metallopolymers with porous properties. Treating digoldazido complex **2-AuN₃** with trigoldacetylide **3-AuPPh₃** or **3-AuPEt₃**, trialkyne **3-H**, tetragoldacetylide **4-AuPPh₃**, or tetraalkyne **4-H** in CH₂Cl₂ affords five iClick network metallopolymers **5-AuPPh₃**, **5-AuPEt₃**, **5-H**, **6-AuPPh₃**, and **6-H**. Confirmation of the iClick network metallopolymers comes from FTIR, ¹³C solid-state cross-coupling magic angle spinning (CPMAS) NMR spectroscopy, thermogravimetric analysis (TGA), differential scanning calorimetry (DSC), and nitrogen and CO₂ sorption analysis. Employing model complexes **7-AuPPh₃**, **7-AuPEt₃**, **7-H**, **8-AuPPh₃**, and **8-H** provide structural insights due to the insolubility of iClick network metallopolymers.

Introduction

Heterogeneous catalysts are useful in industrial processes due to their advantageous sustainability, recyclability, robustness, and ease of catalyst/product separation.^{1,2} Accessible and tunable by a simple choice of building block, porous organic polymers (POPs) have numerous applications^{3–9} in catalysis,^{3,10–12} medicine,^{13,14} gas separation,^{15,16} CO₂ capture,^{17–21} and as sorbents.^{22–29} POPs are highly selective catalysts and can lower process costs.³⁰

A few porous polymers incorporating metal ions (metal-POP) using polypyridines,^{31–33} phthalocyanine,^{34,35} and porphyrins^{36–41} as ligands have been synthesized. Post-polymerization metalation^{31–33,42} or polymerization using monomers bearing metal centers^{31,34–41} are the two methods for incorporating metal ions in porous polymers. The former approach can result in incomplete metalation, and the latter approach requires metal catalysts for polymerization⁴³

In contrast to the methods incorporating metal ions, POP synthesis employs a diverse variety of chemical reactions. Yamamoto,^{44–46} Sonogashira-Hagihara,⁴⁷ Suzuki-Miyaura,⁴⁸ Friedel-Crafts,^{49–51} and copper(I)-catalyzed azide-alkyne cycloaddition (CuAAC),⁵² are some of the reaction types utilized in POP synthesis. Related to this work, highly stable POPs with large surface areas^{53,54} that employ CuAAC in their synthesis are beneficial in small molecule gas capture,^{55–60} photocatalysis,^{61,62} and as supports for heterogeneous catalysis.^{52,63} POPs synthesized using click-based CuAAC are now relatively common in the literature. Absent however, are network polymers synthesized using inorganic click (iClick)⁶⁴

methodologies. An advantage of using iClick is the ability to directly incorporate metal ions into the polymer backbone repeating unit. Demonstrated already for linear polymers,^{65–67} extension of iClick to network polymers has yet to be achieved. Finding a new route to install metal ions in POPs will broaden the application space of these materials.

Scheme 1. A) Early examples of gold(I) 1,2,3-triazolate complexes from cycloaddition reactions,⁶⁸ B) bimetallic iClick reaction of gold(I) azido complex with a gold(I) acetylide,⁶⁴ C) Post-polymerization synthesis of the only metal click-based POP.⁴²

iClick is a rapid, simple, and high yield reaction that is widely applicable to a variety of metals. Some of the first cycloaddition reactions involving metal ions and electron deficient alkynes were reported in the mid-1970's.^{69,70} Related to this work, in 2007, Gray et al. demonstrated the monogold-azide (**1-AuN₃**) cycloaddition with alkynes according to Scheme 1A.^{71–80} Unleashing the possibility of linking metal ions via cycloaddition chemistries, bimetallic complexes produced from metal-azides and metal-acetylides were published by our group in 2011 (Scheme 1B).^{64,80–87} Son et al. reported the only example of a click-based POP that incorporates a metal ion, though the metal addition occurs via post-polymerization functionalization at the periphery of the backbone according to Scheme 1C.⁴² Nonetheless, the Rh-POP has a surface area of 310 m²g⁻¹ and is an active catalyst for the polymerization of arylacetylenes.

† Electronic supplementary information (ESI) available: Experimental details: Tables S1–S4, and Fig. S1–S53. CCDC 2158225 and 2158226. For ESI and crystallographic data in CIF and other electronic format see DOI: 10.1039/x0xx00000x

Here, we present the first use of iClick to build metal containing network organometallic polymers using monomers bearing metal centers without the use of catalysts.

Results

Monomer Synthesis and Characterization: Au(I) Complexes (**2-AuN₃**, **3-AuPEt₃**, and **4-AuPPh₃**).

2-AuN₃. Creating a network polymer using iClick requires the synthesis of several unique monomers. Needed is a digold complex that serves to link the other units in the polymer. Combining (AuCl)₂(PPh₂(C₆H₄)PPh₂)⁸⁸ and silver triflate in THF for 1 d followed by filtration produces (AuOTf)₂(PPh₂(C₆H₄)PPh₂). Dissolving the white powder again in a mixture of THF: MeOH (3:1 v/v) with sodium azide for 1 d produces complex **2-AuN₃** in 81% isolated yield. This two-step process avoids the formation of highly explosive AgN₃.

Evidence for the structural assignment of **2-AuN₃** comes from NMR and IR spectroscopy, and single crystal X-ray diffraction. Attributable to the phosphorous atom, in the ³¹P{¹H} NMR spectrum, a single resonance appears at 30.9 ppm. An absorption at 2052 cm⁻¹ in the FTIR spectrum reveals the presence of the azide functionality. Single crystals suitable for X-ray crystallography deposit from a concentrated solution of **2-AuN₃** in CH₂Cl₂ at -25 °C. C_i-symmetric in solid state and crystallizing in the C2/c space group, X-ray data refinement reveals the dinuclear composition of **2-AuN₃** (Figure 1).

Figure 1. Synthesis and molecular structure of **2-AuN₃** with ellipsoids drawn at the 50% probability level and hydrogen atoms removed for clarity.

3-AuPEt₃ and **4-AuPPh₃**. Porous polymer synthesis requires branching points that extend from multivalent monomers. Combining AuCl(PPh₃) and tetrakis(4-((trimethylsilyl)ethynyl)phenyl)methane⁵⁴ in CH₂Cl₂ for 1 d at ambient temperature yields **4-AuPPh₃** in 71% yield. Identifiable by NMR, IR spectroscopy, and single crystal X-ray diffraction, complex **4-AuPPh₃** is tetranuclear. In the ³¹P{¹H} NMR spectrum of **4-AuPPh₃**, a singlet at 42.3 ppm is attributable to the phosphorous atom on the PPh₃. The acetylide carbon attached to the Au(I) ion resonates at the distinct position of 104.0 ppm in the ¹³C{¹H} NMR spectrum. Assigned to the acetylide stretching vibration, an IR spectrum reveals an absorption at 2119 cm⁻¹. Layering a concentrated CH₂Cl₂ solution of **4-AuPPh₃** with pentane precipitates yellow single crystals suitable for X-

ray diffraction. Figure 2 depicts the molecular structure of **4-AuPPh₃**. Significant rotational disorder within the crystal structure only allows for refinement data of R₁ = 9.79%. Numerous crystallization attempts and X-ray crystallography did not provide better refinement. The rotational disorder comes from the protruding acetylide functionality combined with the presence of a triphenyl phosphine group at the end. Using a slightly modified synthesis⁸⁹ with AuCl(PPh₃) and 1,3,5-tris(trimethylsilyl)ethynylbenzene,⁹⁰ the trivalent derivative **3-AuPEt₃** was also synthesized in 81% yield (Figure S6-S10 in the ESI).

Figure 2. Synthesis and molecular structure of **4-AuPPh₃** with ellipsoids drawn at the 50% probability level and hydrogen atoms removed for clarity.

Synthesis of iClick Model Complexes (**7-AuPPh₃**, **7-AuPEt₃**, **8-AuPPh₃**, **7-H**, and **8-H**).

Synthesis of Model Complexes. Anticipating the need for soluble model complexes, iClick reactions were designed to synthesize small molecule analogues of network polymers. Scheme 2 depicts the iClick reaction between azidogold complex **1-AuN₃**⁹¹ and gold acetylides **3-AuPPh₃**,⁸⁸ **3-AuPEt₃**, and **4-AuPPh₃** to form **7-AuPPh₃**, **7-AuPEt₃**, and **8-AuPPh₃**, respectively. Instead of a difunctional azide, a monoazide caps the ends of monomers **3-AuPPh₃**, **3-AuPEt₃**, **4-AuPPh₃**. Scheme 3 depicts the synthesis of analogous model complexes that employ the organic alkynes **3-H** and **4-H** in place of the Au-acetylides to produce **7-H** and **8-H**.

The iClick reaction occurs readily in CDCl₃ at room temperature to give the five model complexes as yellow powders. Monitoring all five reactions with ¹H and ³¹P{¹H} NMR spectroscopy allows for *in situ* monitoring of product formation. Only temporarily soluble, mixing the azides with acetylides or alkynes eventually results in yellow solid precipitate within

hours presumably due to aurophilic⁸² and π - π interactions.⁹² Changing the solvent and increasing the temperature both fail to solubilize the monomers. Consequently, all five model complexes were characterized *in situ* by solution-phase NMR spectroscopy.

Scheme 2. Synthesis of model complexes (**7-AuPPH₃**, **7-AuPET₃**, and **8-AuPPH₃**) using goldazido complex **1-AuN₃** with trigoldacetylide **3-AuPPH₃** or **3-AuPET₃** and tetragoldacetylide **4-AuPPH₃**.

Monitoring the formation of complexes **7-AuPPH₃**, **7-AuPET₃**, and **8-AuPPH₃** *in situ* with ¹H and ³¹P{¹H} NMR spectroscopy reveals complete conversion of starting materials after 12 h. In the ³¹P{¹H} NMR spectrum (CDCl₃), **7-AuPPH₃** exhibits two singlets at 43.7 and 30.6 ppm, while **8-AuPPH₃** exhibits two singlets at 44.2 and 30.8 ppm attributable to the two PPh₃ ligands. Due to extensive phosphine exchange between PET₃ and PPh₃ the ³¹P{¹H} NMR spectrum of **7-AuPET₃** exhibits numerous signals and precludes an absolute assignment.

Scheme 3. Synthesis of model complexes (**7-H** and **8-H**) using goldazido complex **1-AuN₃** with trialkyne **3-H** and tetraalkyne **4-H**.

Complex **7-H** presents two singlets at 43.3 and 29.9 ppm, while **8-H** exhibits signals at 43.3 and 29.0 ppm in the ³¹P{¹H} NMR spectra (Scheme 3). The downfield signal in the ³¹P{¹H} NMR spectra corresponds to the N-Au-P and the upfield signal is attributable to the C-Au-P phosphorous. The presence of the upfield signal is clear evidence that the Au(I) fragment migrates from the triazolite N-atom to the C-atom. Eq 1 depicts the Au migration. Thus, **7-H** and **8-H** are mixtures of the two C-bound and N-bound derivatives. Previous examples of this rapid isomerization with terminal alkynes in iClick chemistry have

been reported extensively.^{75,82} More evidence for the isomerization comes from the ¹H NMR spectra of both complexes. Indicatives of a proton migration from the carbon atom to the nitrogen of the triazolite ring, complex **7-H** and **8-H** exhibit singlets at 11.85 and 11.66 ppm, respectively.

Complicating the composition of **7-H** and **8-H** further is that their ¹H NMR spectra reveal signals attributable to unreacted alkyne groups. For complex **7-H**, alkyne signals appear as three singlets between 3.48-2.91 ppm, and for the triazolite C-H proton, signals appear downfield between 9.22-8.34 ppm (Page S29 in the ESI). The multiple signals arise from the presence of two isomers noted above and the possibility of one and two unreacted alkynes. The ratio of the different branches within complex **7-H** as determined by NMR integration for C-H:N-H:C≡C-H is as follow: 0.07: 0.64: 0.29. For **8-H** the ratios is 0.42: 0.46: 0.12 (Page S32 in the ESI).

The FTIR spectra of all five model complexes (**7-AuPPH₃**, **7-AuPET₃**, **8-AuPPH₃**, **7-H**, and **8-H**) do not contain an azide⁵⁴ signal near 2058 cm⁻¹, but a small absorption corresponding to unreacted alkyne⁵⁴ on the end groups at 2110 cm⁻¹ supports the conclusion that in this case the iClick is not complete.

Synthesis of iClick network metallopolymers (5-AuPPH₃, 5-AuPET₃, 5-H, 6-AuPPH₃, and 6-H).

Combining the digoldazido complex **2-AuN₃** with trigoldacetylide **3-AuPPH₃** or **3-AuPET₃**, tri-alkyne **3-H**, tetragoldacetylide **4-AuPPH₃**, or tetra-alkyne **4-H** in CH₂Cl₂ yields five different iClick network metallopolymers (**5-AuPPH₃**, **5-AuPET₃**, **5-H**, **6-AuPPH₃**, and **6-H**) according to Scheme 4 and 5. Table S1 in the ESI summarizes the optimization of iClick network metallopolymer syntheses.

Table 1. Effect of reaction time and reaction temperature on the pore properties of iClick network metallopolymers.

iClick polymers	Entry	Reaction temp. (°C)	Reaction time (days)	Specific surface area ^a (m ² g ⁻¹)
5-AuPPH₃	5-AuPPH₃-1	rt	2	27
	5-AuPPH₃-2	50	6	94
	5-AuPPH₃-3	100	3	54
6-AuPPH₃	6-AuPPH₃-1	rt	2	44
	6-AuPPH₃-2	50	6	85
	6-AuPPH₃-3	100	3	47
5-AuPET₃	5-AuPET₃	50	6	30
5-H	5-H-1	50	1	28
	5-H-2	50	6	24
6-H	6-H	50	1	40

^aBET specific surface area in the pressure range of 0.01–0.05 P/P₀ calculated using the BET model.

Mixing a colorless solution of complex **2-AuN₃** with the light-yellow transparent gold(I) acetylide solution of **3-AuPPH₃**, **3-AuPET₃**, or **4-AuPPH₃** in CH₂Cl₂ produces a light yellow suspension of network polymers **5-AuPPH₃**, **5-AuPET₃**, or **6-AuPPH₃**, according to Scheme 4. Purification of the polymers involves simply filtering and washing with CH₂Cl₂. Other

conditions attempted include continuous stirring at room temperature for 2 d, but the same yellow suspension forms (Table 1 entries **5-AuPPH₃-1** and **6-AuPPH₃-1**). Increasing the reaction temperature to 100 °C for 3 d yields brown solids with a colorless solution (Table 1 entries **5-AuPPH₃-3** and **6-AuPPH₃-3**). Heating at 50 °C for 6 d produces light pink network polymers **5-AuPPH₃**, **5-AuPET₃**, and **6-AuPPH₃** that have the highest surface area (Table 1 entries **5-AuPPH₃-2**, **5-AuPET₃**, and **6-AuPPH₃-2**).

Scheme 4. Idealized structure of the iClick network metallopolymers (**5-AuPPH₃**, **5-AuPET₃**, and **6-AuPPH₃**).

It is also possible to produce network polymers using the organic tri- and tetra-alkynes **3-H** and **4-H** according to Scheme 5. Stirring the digoldazido complex **2-AuN₃** with trialkyne **3-H** in CH_2Cl_2 for 1 d at 50 °C results in a cream-colored suspension of **5-H** (Scheme 5). Table 1 entries **5-H-1** and **5-H-2** indicate that reaction time (1 d vs. 6 d) has negligible effect on the porosity outcome. Employing the same reaction conditions and workup produces network polymer **6-H** with similar surface areas.

Scheme 5. Idealized structure of the iClick network metallopolymers (**5-H** and **6-H**).

Examining the porosities of all polymers using nitrogen physisorption at 77 K reveals nitrogen adsorption and desorption isotherms that increase exponentially with increasing pressure indicative of type III isotherm (Figure 3). Nonporous or macroporous solids display type III isotherms. Interestingly, only **6-AuPPH₃-2** exhibits a hysteresis loop desorption isotherm. Determined by N_2 adsorption–desorption isotherms, all five compounds exhibit surface areas below $100 \text{ m}^2\text{g}^{-1}$ (Table 1). Despite the low surface area, these compounds are the first iClick network metallopolymers that incorporate

metal ions directly into the polymer scaffold. One reason for the low porosity may be due to network collapse the porous polymers, a common problem. Various synthetic procedures aimed at avoiding network collapse^{93–95} failed to improve the surface area.

Figure 3. N_2 adsorption-desorption isotherms of iClick network metallopolymers (**5Au-2**, **6Au-2**, **5AuPET₃**, **5H-1**, and **6H**) (solid: adsorption; hollow: desorption).

The FTIR and solid-state ^{13}C CPMAS NMR spectra confirm the formation of all five network polymers (**5-AuPPH₃-2**, **5-AuPET₃**, **5-H-1**, **6-AuPPH₃-2**, and **6-H**). The FTIR spectra of the five polymers no longer exhibit the characteristic signal of the azide group (2052 cm^{-1}) though a small signal for the unreacted gold(I) acetylide (2110 cm^{-1}) appears in all the materials. A new absorption at approximately 1584 cm^{-1} ($\text{N}=\text{N}$ stretch) is attributable to the formation of the expected triazolite ring (Figure S34 in the ESI).

The solid-state ^{13}C CPMAS NMR spectra of the network metallopolymers (**5-AuPPH₃-2**, **5-AuPET₃**, **5-H-1**, **6-AuPPH₃-2**, and **6-H**) match well with the solid-state and solution-phase ^{13}C NMR spectra of the iClick model complexes (**7-AuPPH₃**, **7-AuPET₃**, **8-AuPPH₃**, **7-H**, and **8-H**) (Figure S35–S39). The model complexes all demonstrate one or multiple signals from 150–160 ppm region that are attributable to the triazolite ring. The multiple signals are due to the partially unreacted click reaction, indicating model complex **8-AuPPH₃** has a mixture of mono-clicked, di-clicked, tri-clicked and fully-clicked arms. Similarly, the unreacted alkynes or acetylides exhibit multiple signals near 80 ppm. The NMR data of the model complexes mirrors the network polymers indicating successful iClick reactions.

Figure 4A and 4B depicts the solid-state ^{13}C CPMAS NMR spectra of polymers **5-H-1** and **5-AuPPH₃-2**. **5-AuPPH₃-2** exhibits a resonance at 153.7 ppm that is attributable to the carbon on the triazolite ring and indicates a successful iClick reaction. A broad signal from 139.8–118.0 ppm corresponds to the aromatic carbons and a signal at 65.6 ppm is the unreacted gold(I)acetylides. Assigned to the carbon on the triazolite rings, two additional signals appear at 171.3 and 160.9 ppm, implying a mixture of expected isomers that were observed in complex **7-H** discussed above. The signals appearing at 82.3 and 77.1 ppm are unreacted alkynes that are also observed in model

complexes and in the IR spectrum. The assignments match well with the solid-state and solution-phase ^{13}C NMR spectra of the model complexes **7-AuPPh₃** and **7-H** in Figure S35 and S38. Achieving 100% conversion within an insoluble polymer network is unlikely. Though not the subject of this study those remaining alkyne groups can serve as future sites for post-polymerization functionalization.

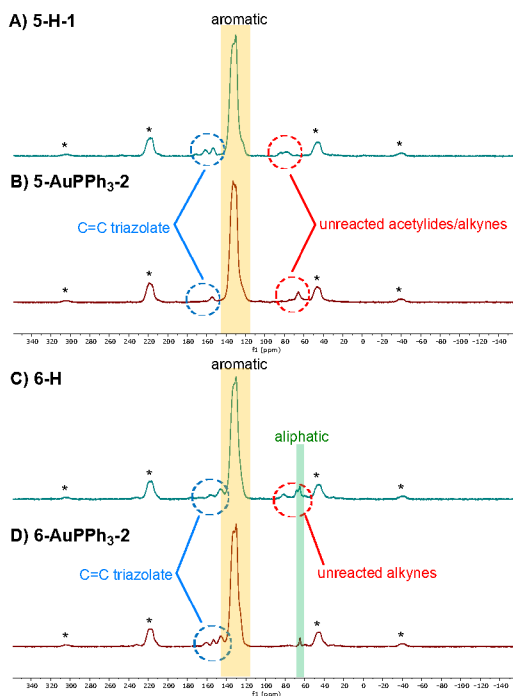

Figure 4. The solid-state ^{13}C CPMAS NMR spectra of **A) 5-H-1**, **B) 5-AuPPh₃-2**, **C) 6-H**, and **D) 6-AuPPh₃-2** (* = spinning side bands (13 kHz)).

Both solid-state ^{13}C CPMAS NMR spectra of polymer **6-H** and **6-AuPPh₃-2** exhibit a broad signal from 139.0–122.3 assigned to the aromatic carbons on the polymer (Figure 4C and 4D). The signal at 65.0 ppm belongs to the central aliphatic carbon of the linker. The triazolate ring carbons resonate at 160.3, 156.1, and 144.7 ppm. For polymer **6-AuPPh₃-2**, the appearance of these signals is due to the unreacted gold acetylides producing a mixture of mono-click, di-click, tri-click and fully-click complexes, which matches the solid-state ^{13}C NMR of the model complex in Figure S36. For polymer **6-H**, the three carbon signals are again attributable to the triazolate mixtures as discussed previously. Two additional alkyne signals at 81.1 and 68.3 ppm appear in the spectrum. Importantly, the solid-state ^{13}C CPMAS NMR spectra of all network polymers matches well with that of the solution-state $^{13}\text{C}\{^1\text{H}\}$ NMR of the model complexes, further supporting the assignments of the polymer structures (Figure S35–S39 in the ESI).

Thermogravimetric analysis (TGA) curves demonstrate that all polymers are thermally stable up to 290 °C (Figure S40 in the ESI). Polymer **5-AuPPh₃-2** and **6-AuPPh₃-2** depict a glass transition temperature (T_g) at -32.8 °C and -40.5 °C in the differential scanning calorimetry (DSC) data between -70 to 220 °C (Figure S41 in the ESI). Notably, the T_g of the DSC result and the absorption analysis were evidence that the iClick polymer

would swell and were considered network polymers. Powder X-ray Diffraction (PXRD) data obtained for **5-AuPPh₃-2** and **6-AuPPh₃-2** confirm their amorphous composition (Figure S53). The TEM and STEM images of polymer **6-AuPPh₃-2** reveal a strong contrast between the polymer and the substrate indicating the presence of Au(I) within the polymer. The sample also contains gold nanoparticles on the surface of the material as a minor impurity (confirmed by EDS). (Figure S49 in the ESI). The STEM EDS spectra demonstrates that the polymer **6-AuPPh₃-2** contains atoms P, while the gold nanoparticles contain only Au (Figure S51 in the ESI).

Discussion

Unreacted alkyne groups suggest the maximum degree of polymerization (DP) was not achieved during the iClick formation of these network polymers and may contribute to the low porosity. Another feature unique to this system that prevents high DP is that azide groups can undergo exchange and shunt polymer growth. Figure 5 depicts the exchange reaction that eliminates an azide group from the monomer with free phosphine. Indeed, NMR studies indicate **2-AuN₃** rapidly exchanges with free phosphine. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of the mixture reveals a resonance attributable to Ph_3AuN_3 (**1-AuN₃**). Finally, bulky PPh_3 groups on the polymer branch also may account for the low surface area for all five complexes. The sterically hindered PPh_3 ligands could fill the pores preventing gas adsorption and resulting in type III isotherms.

Figure 5. (Top) Stacked $^{31}\text{P}\{^1\text{H}\}$ NMR spectra of an *in situ* experiment of adding **2-AuN₃** and **PPh₃** in CH_2Cl_2 for 10 min, **PPh₃** in CH_2Cl_2 , and **2-AuN₃** in CH_2Cl_2 . (Bottom) Illustration of substitution reaction of **2-AuN₃** and **PPh₃**.

Polymers **5-H** and **6-H** have surface areas similar to **5-AuPPh₃-1** and **6-AuPPh₃-1**, indicating that for all four, the bulky PPh_3 ligands on the polymer backbone are filling the pores.

Investigating the CO_2 adsorption properties of all five polymers helps identify the different uptake capacities between the structures. Polymers **5-AuPPh₃-2**, **6-AuPPh₃-2**, and **6-H** all demonstrate CO_2 adsorption capacities of around 30 and 14 mg g^{-1} at 273 and 298 K, respectively (Table S4 in the ESI).

Judging from the higher surface areas of polymers **5-AuPPh₃-2** and **6-AuPPh₃-2**, it is obvious that both polymers demonstrate a higher CO₂ uptake amount.⁵⁴ The CO₂ adsorption capacities in **5-AuPEt₃** and **5-H-1** at 273 and 298 K are around 15 and 8 mg g⁻¹ (Table S4 in the ESI), respectively, which match the lower surface areas of the polymers. These results are lower in comparison to reported organic click-based polymers.^{56,96}

Conclusion

Incorporating the digoldazido complex **2-AuN₃** with gold(I)acetylide or alkynes produces the first series of iClick network metallopolymers that are thermally stable and possess porous properties. This work expands the scope of metal containing porous polymers beyond the ligand classes of polypyridines, phthalocyanine, and porphyrins to now include triazolate ligands. The model complexes **7-AuPPh₃**, **7-AuPEt₃**, **8-AuPPh₃**, **7-H**, and **8-H** help elucidate the characterization features of the insoluble network polymers and revealed incomplete iClick reactions and triazolate isomerization. A measurable T_g , IR spectra showing the consumption of the azide/alkyne groups, solid-state ¹³C NMR data confirming a triazolate within the material, and measurable surface areas, provide evidence supporting the assignment of iClick network polymers. Due to limited solubility, the degree of polymerization and extent of crosslinking remain to be interrogated. This study provides the beginnings of a new strategy to synthesize heterogeneous network metallopolymers with metals incorporated both within the main chain and side branches.

ARTICLE

iClick Synthesis of Network Metallopolymers

Yu-Hsuan Shen,^a Ion Ghiviriga,^a Khalil A. Abboud,^a Kirk S. Schanze,^b Adam S. Veige.*^aReceived 00th January 20xx,
Accepted 00th January 20xx

DOI: 10.1039/x0xx00000x

Described is an approach to preparing the first iClick network metallopolymers with porous properties. Treating digoldazido complex **2-AuN₃** with trigoldacetylide **3-AuPPh₃** or **3-AuPEt₃**, trialkyne **3-H**, tetragoldacetylide **4-AuPPh₃**, or tetraalkyne **4-H** in CH₂Cl₂ affords five iClick network metallopolymers **5-AuPPh₃**, **5-AuPEt₃**, **5-H**, **6-AuPPh₃**, and **6-H**. Confirmation of the iClick network metallopolymers comes from FTIR, ¹³C solid-state cross-coupling magic angle spinning (CPMAS) NMR spectroscopy, thermogravimetric analysis (TGA), differential scanning calorimetry (DSC), and nitrogen and CO₂ sorption analysis. Employing model complexes **7-AuPPh₃**, **7-AuPEt₃**, **7-H**, **8-AuPPh₃**, and **8-H** provide structural insights due to the insolubility of iClick network metallopolymers.

Introduction

Heterogeneous catalysts are useful in industrial processes due to their advantageous sustainability, recyclability, robustness, and ease of catalyst/product separation.^{1,2} Accessible and tunable by a simple choice of building block, porous organic polymers (POPs) have numerous applications^{3–9} in catalysis,^{3,10–12} medicine,^{13,14} gas separation,^{15,16} CO₂ capture,^{17–21} and as sorbents.^{22–29} POPs are highly selective catalysts and can lower process costs.³⁰

A few porous polymers incorporating metal ions (metal-POP) using polypyridines,^{31–33} phthalocyanine,^{34,35} and porphyrins^{36–41} as ligands have been synthesized. Post-polymerization metalation^{31–33,42} or polymerization using monomers bearing metal centers^{31,34–41} are the two methods for incorporating metal ions in porous polymers. The former approach can result in incomplete metalation, and the latter approach requires metal catalysts for polymerization⁴³

In contrast to the methods incorporating metal ions, POP synthesis employs a diverse variety of chemical reactions. Yamamoto,^{44–46} Sonogashira-Hagihara,⁴⁷ Suzuki-Miyaura,⁴⁸ Friedel-Crafts,^{49–51} and copper(I)-catalyzed azide-alkyne cycloaddition (CuAAC),⁵² are some of the reaction types utilized in POP synthesis. Related to this work, highly stable POPs with large surface areas^{53,54} that employ CuAAC in their synthesis are beneficial in small molecule gas capture,^{55–60} photocatalysis,^{61,62} and as supports for heterogeneous catalysis.^{52,63} POPs synthesized using click-based CuAAC are now relatively common in the literature. Absent however, are network polymers synthesized using inorganic click (iClick)⁶⁴

methodologies. An advantage of using iClick is the ability to directly incorporate metal ions into the polymer backbone repeating unit. Demonstrated already for linear polymers,^{65–67} extension of iClick to network polymers has yet to be achieved. Finding a new route to install metal ions in POPs will broaden the application space of these materials.

Scheme 1. A) Early examples of gold(I) 1,2,3-triazolate complexes from cycloaddition reactions,⁶⁸ B) bimetallic iClick reaction of gold(I) azido complex with a gold(I) acetylide,⁶⁴ C) Post-polymerization synthesis of the only metal click-based POP.⁴²

iClick is a rapid, simple, and high yield reaction that is widely applicable to a variety of metals. Some of the first cycloaddition reactions involving metal ions and electron deficient alkynes were reported in the mid-1970's.^{69,70} Related to this work, in 2007, Gray et al. demonstrated the monogold-azide (**1-AuN₃**) cycloaddition with alkynes according to Scheme 1A.^{71–80} Unleashing the possibility of linking metal ions via cycloaddition chemistries, bimetallic complexes produced from metal-azides and metal-acetylides were published by our group in 2011 (Scheme 1B).^{64,80–87} Son et al. reported the only example of a click-based POP that incorporates a metal ion, though the metal addition occurs via post-polymerization functionalization at the periphery of the backbone according to Scheme 1C.⁴² Nonetheless, the Rh-POP has a surface area of 310 m²g⁻¹ and is an active catalyst for the polymerization of arylacetylenes.

† Electronic supplementary information (ESI) available: Experimental details: Tables S1–S4, and Fig. S1–S53. CCDC 2158225 and 2158226. For ESI and crystallographic data in CIF and other electronic format see DOI: 10.1039/x0xx00000x

Here, we present the first use of iClick to build metal containing network organometallic polymers using monomers bearing metal centers without the use of catalysts.

Results

Monomer Synthesis and Characterization: Au(I) Complexes (2-AuN₃, 3-AuPET₃, and 4-AuPPh₃).

2-AuN₃. Creating a network polymer using iClick requires the synthesis of several unique monomers. Needed is a digold complex that serves to link the other units in the polymer. Combining (AuCl)₂(PPh₂(C₆H₄)PPh₂)⁸⁸ and silver triflate in THF for 1 d followed by filtration produces (AuOTf)₂(PPh₂(C₆H₄)PPh₂). Dissolving the white powder again in a mixture of THF: MeOH (3:1 v/v) with sodium azide for 1 d produces complex **2-AuN₃** in 81% isolated yield. This two-step process avoids the formation of highly explosive AgN₃.

Evidence for the structural assignment of **2-AuN₃** comes from NMR and IR spectroscopy, and single crystal X-ray diffraction. Attributable to the phosphorous atom, in the ³¹P{¹H} NMR spectrum, a single resonance appears at 30.9 ppm. An absorption at 2052 cm⁻¹ in the FTIR spectrum reveals the presence of the azide functionality. Single crystals suitable for X-ray crystallography deposit from a concentrated solution of **2-AuN₃** in CH₂Cl₂ at -25 °C. C_i-symmetric in solid state and crystallizing in the C2/c space group, X-ray data refinement reveals the dinuclear composition of **2-AuN₃** (Figure 1).

Figure 1. Synthesis and molecular structure of **2-AuN₃**, with ellipsoids drawn at the 50% probability level and hydrogen atoms removed for clarity.

3-AuPET₃ and 4-AuPPh₃. Porous polymer synthesis requires branching points that extend from multivalent monomers. Combining AuCl(PPh₃) and tetrakis(4-((trimethylsilyl)ethynyl)phenyl)methane⁵⁴ in CH₂Cl₂ for 1 d at ambient temperature yields **4-AuPPh₃** in 71% yield. Identifiable by NMR, IR spectroscopy, and single crystal X-ray diffraction, complex **4-AuPPh₃** is tetranuclear. In the ³¹P{¹H} NMR spectrum of **4-AuPPh₃**, a singlet at 42.3 ppm is attributable to the phosphorous atom on the PPh₃. The acetylide carbon attached to the Au(I) ion resonates at the distinct position of 104.0 ppm in the ¹³C{¹H} NMR spectrum. Assigned to the acetylide stretching vibration, an IR spectrum reveals an absorption at 2119 cm⁻¹. Layering a concentrated CH₂Cl₂ solution of **4-AuPPh₃** with pentane precipitates yellow single crystals suitable for X-

ray diffraction. Figure 2 depicts the molecular structure of **4-AuPPh₃**. Significant rotational disorder within the crystal structure only allows for refinement data of R₁ = 9.79%. Numerous crystallization attempts and X-ray crystallography did not provide better refinement. The rotational disorder comes from the protruding acetylide functionality combined with the presence of a triphenyl phosphine group at the end. Using a slightly modified synthesis⁸⁹ with AuCl(PPh₃) and 1,3,5-tris(trimethylsilyl)ethynylbenzene,⁹⁰ the trivalent derivative **3-AuPET₃** was also synthesized in 81% yield (Figure S6-S10 in the ESI).

Figure 2. Synthesis and molecular structure of **4-AuPPh₃** with ellipsoids drawn at the 50% probability level and hydrogen atoms removed for clarity.

Synthesis of iClick Model Complexes (7-AuPPh₃, 7-AuPET₃, 8-AuPPh₃, 7-H, and 8-H).

Synthesis of Model Complexes. Anticipating the need for soluble model complexes, iClick reactions were designed to synthesize small molecule analogues of network polymers. Scheme 2 depicts the iClick reaction between azidogold complex **1-AuN₃**⁹¹ and gold acetylides **3-AuPPh₃**,⁸⁸ **3-AuPET₃**, and **4-AuPPh₃** to form **7-AuPPh₃**, **7-AuPET₃**, and **8-AuPPh₃**, respectively. Instead of a difunctional azide, a monoazide caps the ends of monomers **3-AuPPh₃**, **3-AuPET₃**, **4-AuPPh₃**. Scheme 3 depicts the synthesis of analogous model complexes that employ the organic alkynes **3-H** and **4-H** in place of the Au-acetylides to produce **7-H** and **8-H**.

The iClick reaction occurs readily in CDCl₃ at room temperature to give the five model complexes as yellow powders. Monitoring all five reactions with ¹H and ³¹P{¹H} NMR spectroscopy allows for *in situ* monitoring of product formation. Only temporarily soluble, mixing the azides with acetylides or alkynes eventually results in yellow solid precipitate within

hours presumably due to aurophilic⁸² and π - π interactions.⁹² Changing the solvent and increasing the temperature both fail to solubilize the monomers. Consequently, all five model complexes were characterized *in situ* by solution-phase NMR spectroscopy.

Scheme 2. Synthesis of model complexes (**7-AuPPH₃**, **7-AuPET₃**, and **8-AuPPH₃**) using goldazido complex **1-AuN₃** with trigoldacetylide **3-AuPPH₃** or **3-AuPET₃** and tetragoldacetylide **4-AuPPH₃**.

Monitoring the formation of complexes **7-AuPPH₃**, **7-AuPET₃**, and **8-AuPPH₃** *in situ* with ¹H and ³¹P{¹H} NMR spectroscopy reveals complete conversion of starting materials after 12 h. In the ³¹P{¹H} NMR spectrum (CDCl₃), **7-AuPPH₃** exhibits two singlets at 43.7 and 30.6 ppm, while **8-AuPPH₃** exhibits two singlets at 44.2 and 30.8 ppm attributable to the two PPh₃ ligands. Due to extensive phosphine exchange between PET₃ and PPh₃ the ³¹P{¹H} NMR spectrum of **7-AuPET₃** exhibits numerous signals and precludes an absolute assignment.

Scheme 3. Synthesis of model complexes (**7-H** and **8-H**) using goldazido complex **1-AuN₃** with trialkyne **3-H** and tetraalkyne **4-H**.

Complex **7-H** presents two singlets at 43.3 and 29.9 ppm, while **8-H** exhibits signals at 43.3 and 29.0 ppm in the ³¹P{¹H} NMR spectra (Scheme 3). The downfield signal in the ³¹P{¹H} NMR spectra corresponds to the N-Au-P and the upfield signal is attributable to the C-Au-P phosphorous. The presence of the upfield signal is clear evidence that the Au(I) fragment migrates from the triazolite N-atom to the C-atom. Eq 1 depicts the Au migration. Thus, **7-H** and **8-H** are mixtures of the two C-bound and N-bound derivatives. Previous examples of this rapid isomerization with terminal alkynes in iClick chemistry have

been reported extensively.^{75,82} More evidence for the isomerization comes from the ¹H NMR spectra of both complexes. Indicatives of a proton migration from the carbon atom to the nitrogen of the triazolite ring, complex **7-H** and **8-H** exhibit singlets at 11.85 and 11.66 ppm, respectively.

Complicating the composition of **7-H** and **8-H** further is that their ¹H NMR spectra reveal signals attributable to unreacted alkyne groups. For complex **7-H**, alkyne signals appear as three singlets between 3.48-2.91 ppm, and for the triazolite C-H proton, signals appear downfield between 9.22-8.34 ppm (Page S29 in the ESI). The multiple signals arise from the presence of two isomers noted above and the possibility of one and two unreacted alkynes. The ratio of the different branches within complex **7-H** as determined by NMR integration for C-H:N-H:C≡C-H is as follow: 0.07: 0.64: 0.29. For **8-H** the ratios is 0.42: 0.46: 0.12 (Page S32 in the ESI).

The FTIR spectra of all five model complexes (**7-AuPPH₃**, **7-AuPET₃**, **8-AuPPH₃**, **7-H**, and **8-H**) do not contain an azide⁵⁴ signal near 2058 cm⁻¹, but a small absorption corresponding to unreacted alkyne⁵⁴ on the end groups at 2110 cm⁻¹ supports the conclusion that in this case the iClick is not complete.

Synthesis of iClick network metallopolymers (5-AuPPH₃, 5-AuPET₃, 5-H, 6-AuPPH₃, and 6-H).

Combining the digoldazido complex **2-AuN₃** with trigoldacetylide **3-AuPPH₃** or **3-AuPET₃**, tri-alkyne **3-H**, tetragoldacetylide **4-AuPPH₃**, or tetra-alkyne **4-H** in CH₂Cl₂ yields five different iClick network metallopolymers (**5-AuPPH₃**, **5-AuPET₃**, **5-H**, **6-AuPPH₃**, and **6-H**) according to Scheme 4 and 5. Table S1 in the ESI summarizes the optimization of iClick network metallopolymer syntheses.

Table 1. Effect of reaction time and reaction temperature on the pore properties of iClick network metallopolymers.

iClick polymers	Entry	Reaction temp. (°C)	Reaction time (days)	Specific surface area ^a (m ² g ⁻¹)
5-AuPPH₃	5-AuPPH₃-1	rt	2	27
	5-AuPPH₃-2	50	6	94
	5-AuPPH₃-3	100	3	54
6-AuPPH₃	6-AuPPH₃-1	rt	2	44
	6-AuPPH₃-2	50	6	85
	6-AuPPH₃-3	100	3	47
5-AuPET₃	5-AuPET₃	50	6	30
5-H	5-H-1	50	1	28
	5-H-2	50	6	24
6-H	6-H	50	1	40

^aBET specific surface area in the pressure range of 0.01–0.05 P/P₀ calculated using the BET model.

Mixing a colorless solution of complex **2-AuN₃** with the light-yellow transparent gold(I) acetylide solution of **3-AuPPH₃**, **3-AuPET₃**, or **4-AuPPH₃** in CH₂Cl₂ produces a light yellow suspension of network polymers **5-AuPPH₃**, **5-AuPET₃**, or **6-AuPPH₃**, according to Scheme 4. Purification of the polymers involves simply filtering and washing with CH₂Cl₂. Other

conditions attempted include continuous stirring at room temperature for 2 d, but the same yellow suspension forms (Table 1 entries **5-AuPPH₃-1** and **6-AuPPH₃-1**). Increasing the reaction temperature to 100 °C for 3 d yields brown solids with a colorless solution (Table 1 entries **5-AuPPH₃-3** and **6-AuPPH₃-3**). Heating at 50 °C for 6 d produces light pink network polymers **5-AuPPH₃**, **5-AuPET₃**, and **6-AuPPH₃** that have the highest surface area (Table 1 entries **5-AuPPH₃-2**, **5-AuPET₃**, and **6-AuPPH₃-2**).

Scheme 4. Idealized structure of the iClick network metallopolymers (**5-AuPPH₃**, **5-AuPET₃**, and **6-AuPPH₃**).

It is also possible to produce network polymers using the organic tri- and tetra-alkynes **3-H** and **4-H** according to Scheme 5. Stirring the digoldazido complex **2-AuN₃** with trialkyne **3-H** in CH_2Cl_2 for 1 d at 50 °C results in a cream-colored suspension of **5-H** (Scheme 5). Table 1 entries **5-H-1** and **5-H-2** indicate that reaction time (1 d vs. 6 d) has negligible effect on the porosity outcome. Employing the same reaction conditions and workup produces network polymer **6-H** with similar surface areas.

Scheme 5. Idealized structure of the iClick network metallopolymers (**5-H** and **6-H**).

Examining the porosities of all polymers using nitrogen physisorption at 77 K reveals nitrogen adsorption and desorption isotherms that increase exponentially with increasing pressure indicative of type III isotherm (Figure 3). Nonporous or macroporous solids display type III isotherms. Interestingly, only **6-AuPPH₃-2** exhibits a hysteresis loop desorption isotherm. Determined by N_2 adsorption–desorption isotherms, all five compounds exhibit surface areas below $100 \text{ m}^2\text{g}^{-1}$ (Table 1). Despite the low surface area, these compounds are the first iClick network metallopolymers that incorporate

metal ions directly into the polymer scaffold. One reason for the low porosity maybe due to network collapse the porous polymers, a common problem. Various synthetic procedures aimed at avoiding network collapse^{93–95} failed to improve the surface area.

Figure 3. N_2 adsorption-desorption isotherms of iClick network metallopolymers (**5Au-2**, **6Au-2**, **5AuPET₃**, **5H-1**, and **6H**) (solid: adsorption; hollow: desorption).

The FTIR and solid-state ^{13}C CPMAS NMR spectra confirm the formation of all five network polymers (**5-AuPPH₃-2**, **5-AuPET₃**, **5-H-1**, **6-AuPPH₃-2**, and **6-H**). The FTIR spectra of the five polymers no longer exhibit the characteristic signal of the azide group (2052 cm^{-1}) though a small signal for the unreacted gold(I) acetylide (2110 cm^{-1}) appears in all the materials. A new absorption at approximately 1584 cm^{-1} ($\text{N}=\text{N}$ stretch) is attributable to the formation of the expected triazolate ring (Figure S34 in the ESI).

The solid-state ^{13}C CPMAS NMR spectra of the network metallopolymers (**5-AuPPH₃-2**, **5-AuPET₃**, **5-H-1**, **6-AuPPH₃-2**, and **6-H**) match well with the solid-state and solution-phase ^{13}C NMR spectra of the iClick model complexes (**7-AuPPH₃**, **7-AuPET₃**, **8-AuPPH₃**, **7-H**, and **8-H**) (Figure S35–S39). The model complexes all demonstrate one or multiple signals from 150–160 ppm region that are attributable to the triazolate ring. The multiple signals are due to the partially unreacted click reaction, indicating model complex **8-AuPPH₃** has a mixture of mono-clicked, di-clicked, tri-clicked and fully-clicked arms. Similarly, the unreacted alkynes or acetylides exhibit multiple signals near 80 ppm. The NMR data of the model complexes mirrors the network polymers indicating successful iClick reactions.

Figure 4A and 4B depicts the solid-state ^{13}C CPMAS NMR spectra of polymers **5-H-1** and **5-AuPPH₃-2**. **5-AuPPH₃-2** exhibits a resonance at 153.7 ppm that is attributable to the carbon on the triazolate ring and indicates a successful iClick reaction. A broad signal from 139.8–118.0 ppm corresponds to the aromatic carbons and a signal at 65.6 ppm is the unreacted gold(I)acetylides. Assigned to the carbon on the triazolate rings, two additional signals appear at 171.3 and 160.9 ppm, implying a mixture of expected isomers that were observed in complex **7-H** discussed above. The signals appearing at 82.3 and 77.1 ppm are unreacted alkynes that are also observed in model

complexes and in the IR spectrum. The assignments match well with the solid-state and solution-phase ^{13}C NMR spectra of the model complexes **7-AuPPh₃** and **7-H** in Figure S35 and S38. Achieving 100% conversion within an insoluble polymer network is unlikely. Though not the subject of this study those remaining alkyne groups can serve as future sites for post-polymerization functionalization.

Figure 4. The solid-state ^{13}C CPMAS NMR spectra of **A) 5-H-1**, **B) 5-AuPPh₃-2**, **C) 6-H**, and **D) 6-AuPPh₃-2** (* = spinning side bands (13 kHz)).

Both solid-state ^{13}C CPMAS NMR spectra of polymer **6-H** and **6-AuPPh₃-2** exhibit a broad signal from 139.0–122.3 assigned to the aromatic carbons on the polymer (Figure 4C and 4D). The signal at 65.0 ppm belongs to the central aliphatic carbon of the linker. The triazolate ring carbons resonate at 160.3, 156.1, and 144.7 ppm. For polymer **6-AuPPh₃-2**, the appearance of these signals is due to the unreacted gold acetylides producing a mixture of mono-click, di-click, tri-click and fully-click complexes, which matches the solid-state ^{13}C NMR of the model complex in Figure S36. For polymer **6-H**, the three carbon signals are again attributable to the triazolate mixtures as discussed previously. Two additional alkyne signals at 81.1 and 68.3 ppm appear in the spectrum. Importantly, the solid-state ^{13}C CPMAS NMR spectra of all network polymers matches well with that of the solution-state $^{13}\text{C}\{^1\text{H}\}$ NMR of the model complexes, further supporting the assignments of the polymer structures (Figure S35–S39 in the ESI).

Thermogravimetric analysis (TGA) curves demonstrate that all polymers are thermally stable up to 290 °C (Figure S40 in the ESI). Polymer **5-AuPPh₃-2** and **6-AuPPh₃-2** depict a glass transition temperature (T_g) at -32.8 °C and -40.5 °C in the differential scanning calorimetry (DSC) data between -70 to 220 °C (Figure S41 in the ESI). Notably, the T_g of the DSC result and the absorption analysis were evidence that the iClick polymer

would swell and were considered network polymers. Powder X-ray Diffraction (PXRD) data obtained for **5-AuPPh₃-2** and **6-AuPPh₃-2** confirm their amorphous composition (Figure S53). The TEM and STEM images of polymer **6-AuPPh₃-2** reveal a strong contrast between the polymer and the substrate indicating the presence of Au(I) within the polymer. The sample also contains gold nanoparticles on the surface of the material as a minor impurity (confirmed by EDS). (Figure S49 in the ESI). The STEM EDS spectra demonstrates that the polymer **6-AuPPh₃-2** contains atoms P, while the gold nanoparticles contain only Au (Figure S51 in the ESI).

Discussion

Unreacted alkyne groups suggest the maximum degree of polymerization (DP) was not achieved during the iClick formation of these network polymers and may contribute to the low porosity. Another feature unique to this system that prevents high DP is that azide groups can undergo exchange and shunt polymer growth. Figure 5 depicts the exchange reaction that eliminates an azide group from the monomer with free phosphine. Indeed, NMR studies indicate **2-AuN₃** rapidly exchanges with free phosphine. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of the mixture reveals a resonance attributable to Ph_3AuN_3 (**1-AuN₃**). Finally, bulky PPh_3 groups on the polymer branch also may account for the low surface area for all five complexes. The sterically hindered PPh_3 ligands could fill the pores preventing gas adsorption and resulting in type III isotherms.

Figure 5. (Top) Stacked $^{31}\text{P}\{^1\text{H}\}$ NMR spectra of an *in situ* experiment of adding **2-AuN₃** and **PPh₃** in CH_2Cl_2 for 10 min, **PPh₃** in CH_2Cl_2 , and **2-AuN₃** in CH_2Cl_2 . (Bottom) Illustration of substitution reaction of **2-AuN₃** and **PPh₃**.

Polymers **5-H** and **6-H** have surface areas similar to **5-AuPPh₃-1** and **6-AuPPh₃-1**, indicating that for all four, the bulky PPh_3 ligands on the polymer backbone are filling the pores.

Investigating the CO_2 adsorption properties of all five polymers helps identify the different uptake capacities between the structures. Polymers **5-AuPPh₃-2**, **6-AuPPh₃-2**, and **6-H** all demonstrate CO_2 adsorption capacities of around 30 and 14 mg g^{-1} at 273 and 298 K, respectively (Table S4 in the ESI).

Judging from the higher surface areas of polymers **5-AuPPh₃-2** and **6-AuPPh₃-2**, it is obvious that both polymers demonstrate a higher CO₂ uptake amount.⁵⁴ The CO₂ adsorption capacities in **5-AuPEt₃** and **5-H-1** at 273 and 298 K are around 15 and 8 mg g⁻¹ (Table S4 in the ESI), respectively, which match the lower surface areas of the polymers. These results are lower in comparison to reported organic click-based polymers.^{56,96}

Conclusion

Incorporating the digoldazido complex **2-AuN₃** with gold(I)acetylide or alkynes produces the first series of iClick network metallopolymers that are thermally stable and possess porous properties. This work expands the scope of metal containing porous polymers beyond the ligand classes of polypyridines, phthalocyanine, and porphyrins to now include triazolate ligands. The model complexes **7-AuPPh₃**, **7-AuPEt₃**, **8-AuPPh₃**, **7-H**, and **8-H** help elucidate the characterization features of the insoluble network polymers and revealed incomplete iClick reactions and triazolate isomerization. A measurable T_g , IR spectra showing the consumption of the azide/alkyne groups, solid-state ¹³C NMR data confirming a triazolate within the material, and measurable surface areas, provide evidence supporting the assignment of iClick network polymers. Due to limited solubility, the degree of polymerization and extent of crosslinking remain to be interrogated. This study provides the beginnings of a new strategy to synthesize heterogeneous network metallopolymers with metals incorporated both within the main chain and side branches.
