The reactivity of tris(*ortho*-carboranyl)borane with ubiquitous Lewis bases reveals only small Lewis bases bind. The tremendous bulk and Lewis acidity is leveraged in frustrated Lewis pair Si-H cleavage with a wider range of Lewis bases and greater efficacy than B(C₆F₅)₃.

Introduction

Frustrated Lewis pairs (FLPs) arise from the combination of a Lewis acid and Lewis base that, due to steric demands, do not form a classical adduct.¹ The quenched reactivity can be taken advantage of to activate bonds, exemplified in the pioneering reversible metal-free activation of H₂ by Stephan with the arene bridged intramolecular FLP, Me₂PC₆F₄B(C₆F₅)₂ (Mes = 2,4,6 trimethylphenyl).² The field has exploded with both inter- and intra-molecular systems being applied to activate a plethora of bonds and in many cases, act as catalysts.³ While the application of FLPs is widespread, the prevalent Lewis acid reagents in these systems have been dominated by fluoroarylboranes, especially tris(pentafluorophenyl)borane [B(C₆F₅)₃].^{3b, 4} The compatible Lewis bases require bulk to preclude coordination and accordingly, bulky phosphines and amines have been common Lewis base partners.⁵

A bulkier Lewis acid could open the gateway to a series of smaller Lewis bases that are incompatible for FLP chemistry with fluoroarylboranes and perhaps new substrates for catalysis. Our team recently synthesized a Lewis acid candidate for FLP chemistry that uses an alternative approach to fluorine loading of aryl groups to enhance Lewis acidity, *ortho*-carboranes as large electron withdrawing substituents.⁶ Tris(*ortho*-carboranyl)borane (BoCb₃) is accessed in one pot from three commercially available chemicals (Figure 1a).⁷ Mono- and bis-carboranylboranes have reported higher Lewis acidity than their aryl analogues but they are not as Lewis acidic as BoCb₃.^{8,6d, 9} A competition experiment reacting an equimolar

amount of acetonitrile with B(C₆F₅)₃ and BoCb₃ indicates preferential binding to BoCb₃. Calculated fluoride and hydride affinities, as well as ammonia and acetonitrile binding affinities, exceed the values reported for fluoroarylboranes (Figure 1b).^{7, 10} In addition to the greater Lewis acidity, the calculated steric profile of the fluoride adduct of BoCb₃ revealed greater bulk at boron than B(C₆F₅)₃ with a buried volume of 71.9% compared to 58.9%.¹¹ With the greater bulk of BoCb₃, a wider library of Lewis bases could be compatible for FLP chemistry which is herein investigated. In the disclosure of BoCb₃, acetonitrile, triethylphosphine oxide, and benzaldehyde adducts were reported (Figure 1c).⁷

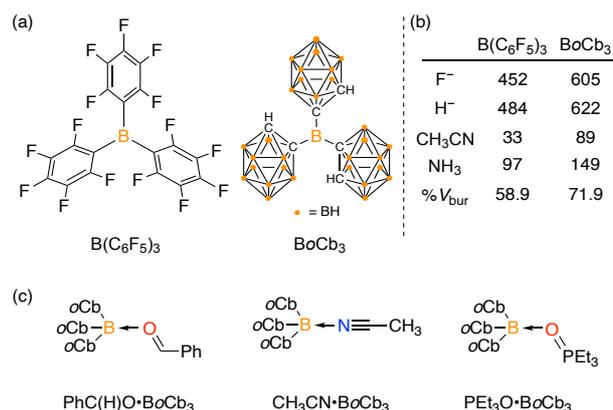

Figure 1: (a) Structures of B(C₆F₅)₃ and BoCb₃ (oCb = *ortho*-carborane). (b) Calculated properties of B(C₆F₅)₃ and BoCb₃ [F⁻ = fluoride ion affinity, H⁻ = hydride ion affinity, CH₃CN = acetonitrile affinity, and NH₃ = ammonia affinity; all are in kJmol⁻¹; %V_{bur} = % buried volume of the corresponding fluoride adducts]. (c) Known BoCb₃ adducts.

Results and Discussions

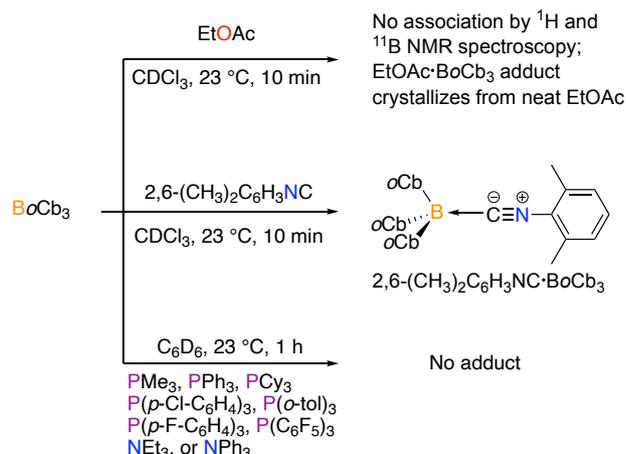

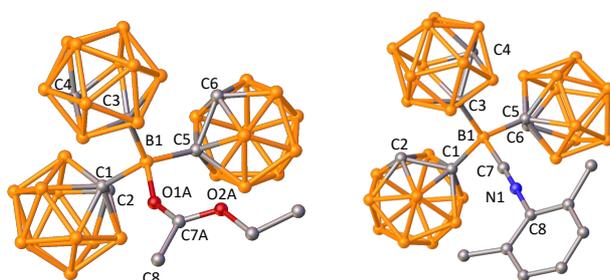

Scheme 1: Reactions of B(C₆F₅)₃ with various Lewis bases.

Figure 2: Solid state structures of EtOAc·B(C₆F₅)₃ (left) and 2,6-(CH₃)₂C₆H₃NC·B(C₆F₅)₃ (right). Ellipsoids depicted at the 50% probability level and hydrogen atoms are omitted for clarity. EtOAc·B(C₆F₅)₃ is disordered and only the major occupancy component is shown. Selected bond lengths (Å) and angles (°): EtOAc·B(C₆F₅)₃: B(1)–O(1A) 1.70(2), O(1A)–C(7A) 1.260(2), B(1)–O(1A)–C(7A) 148.7(3); 2,6-(CH₃)₂C₆H₃NC·B(C₆F₅)₃: B(1)–C(7) 1.6373(15), C(7)–N(1) 1.1448(14), B(1)–C(7)–N(1) 175.74(11).

To determine whether FLPs are possible with B(C₆F₅)₃ a variety of commercially available Lewis bases were screened (Scheme 1). The reaction of B(C₆F₅)₃ with an equivalent of ethylacetate in CDCl₃ showed no change by ^1H and ^{11}B NMR spectroscopy but the adduct could be crystallized in neat ethylacetate with the structure confirmed by a single crystal X-ray diffraction study (EtOAc·B(C₆F₅)₃, Scheme 1, Figure 2). Dissolving the crystals in CDCl₃ revealed only free ethylacetate and B(C₆F₅)₃ indicating the adduct is not resilient in CDCl₃ solution. Reaction of B(C₆F₅)₃ with 2,6-(CH₃)₂C₆H₃NC generated the adduct, 2,6-(CH₃)₂C₆H₃NC·B(C₆F₅)₃, as confirmed by a single crystal X-ray diffraction study. In this case, the adduct remains intact in CDCl₃ solution as confirmed by ^1H NMR spectroscopy with the three *ortho* C–H resonances shifted upfield (5.02 ppm to 4.72 ppm) along with the disappearance of the tricoordinate peak at 66.9 ppm in the ^{11}B NMR spectrum. The corresponding ethylacetate and 2,6-(CH₃)₂C₆H₃NC adducts with B(C₆F₅)₃ have been reported and are resilient in solution.¹² Since the Lewis acidity of B(C₆F₅)₃ is

higher than B(C₆F₅)₃ but only the ethylacetate adduct of B(C₆F₅)₃ dissociates in solution, the dissociation is presumed to occur from the larger steric profile of B(C₆F₅)₃ versus B(C₆F₅)₃. This suggests that B(C₆F₅)₃ should be a good candidate as a Lewis acid for FLP chemistry. The reactions of B(C₆F₅)₃ with an array of phosphines [PMe₃, PPh₃, PCy₃, P(*o*-tol)₃, P(*p*-Cl-C₆H₄)₃, P(*p*-F-C₆H₄)₃, and P(C₆F₅)₃] and amine bases (NEt₃ and NPh₃) in C₆D₆ did not result in any change in the ^1H and $^{31}\text{P}\{^1\text{H}\}$ NMR spectra from the respective starting materials, indicating adducts are not formed. It has been established that B(C₆F₅)₃ makes adducts with PMe₃, PPh₃, NEt₃, PCy₃, P(*p*-Cl-C₆H₄)₃, and P(*p*-F-C₆H₄)₃ but not with P(*o*-tol)₃ or P(C₆F₅)₃.¹³ From this, the breadth of Lewis bases for FLP generation with B(C₆F₅)₃ is much greater than B(C₆F₅)₃.

To determine if a B(C₆F₅)₃ adduct or FLP could induce Si–H cleavage, we first screened the adducts, CH₃CN·B(C₆F₅)₃, PhC(H)O·B(C₆F₅)₃, Et₃PO·B(C₆F₅)₃, EtOAc·B(C₆F₅)₃, and 2,6-(CH₃)₂C₆H₃NC·B(C₆F₅)₃. None of the adducts showed any sign of reaction with an equivalent of silane at 23 °C in C₆H₆. Upon screening the phosphine FLP systems, the stoichiometric reactions of B(C₆F₅)₃ and many phosphines (PR₃; R = Me, Ph, Cy, *p*-Cl-C₆H₄) with HSiEt₃ led to the ion pairs [R₃PSiEt₃][HB(C₆F₅)₃] in high yields while reactions with P(*o*-tol)₃ and P(*p*-F-C₆H₄)₃ required two equivalents of silane to consume the phosphine and B(C₆F₅)₃ starting materials. The reduced reactivity of P(*o*-tol)₃ is rationalized by steric bulk while P(*p*-F-C₆H₄)₃ is from the lower Lewis basicity from the electron withdrawing fluorine. Further corroborating this, the fully fluorinated variant, P(C₆F₅)₃, did not react at all with HSiEt₃ in the presence of B(C₆F₅)₃, even with 5 equivalents of silane. The Tolman cone angles for P(*o*-tol)₃ and P(C₆F₅)₃ are similar (~184°) which imply the electron withdrawing C₆F₅ group shuts down the reactivity.¹⁴ Upon examining the amines, the FLP reaction of B(C₆F₅)₃, NEt₃, and HSiEt₃ formed the [Et₃NSiEt₃][HB(C₆F₅)₃] ion pair but the reaction with NPh₃ did not show any change in the ^1H NMR and ^{11}B NMR spectra. The diminished reactivity is rationalized by the weaker Lewis basicity of NPh₃. Comparing the reactivity with the same phosphines and B(C₆F₅)₃ reported in the literature, the Ph₃P·B(C₆F₅)₃ adduct required 10 equivalents of HSiEt₃ to achieve full conversion to the ion pair while (*p*-Cl-C₆H₄)₃P·B(C₆F₅)₃ and (*p*-F-C₆H₄)₃P·B(C₆F₅)₃ resulted in only partial conversion with ten equivalents.^{13b} The Cy₃P·B(C₆F₅)₃ adduct did not react with HSiEt₃.^{13b} The results indicate that B(C₆F₅)₃ is compatible with more Lewis bases to induce FLP Si–H cleavage.

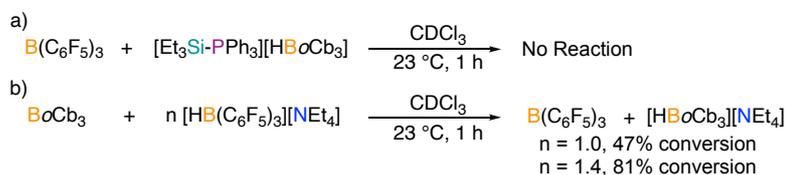

In the literature, solution NMR spectroscopy indicates that HSiEt₃ interacts with B(C₆F₅)₃ and heating to 60 °C leads to the formation of Piers' borane, HB(C₆F₅)₂.¹⁵ Contrarily, solution NMR spectroscopy does not reveal any interaction of B(C₆F₅)₃ with and heating to 120 °C did not result in any reaction.

In characterizing the ion pairs, in the phosphine reactions (Table 1), the $^{31}\text{P}\{^1\text{H}\}$ NMR spectra showed the resonance for the [R₃PSiEt₃] cation shift downfield from the free phosphine (R = Me -25.9 ppm cf. -62.0 ppm, R = Ph -2.9 ppm cf. -5.6 ppm, R = Cy

LB	n	Product	$^{31}\text{P}\{\text{H}\}$ (ppm)	Conversion ^a	Isolated Yield

Table 1: Reactions of BoCb₃ and Lewis bases, with HSiEt₃. (NR = No reaction). ^aConversions determined by quantitative ¹H NMR spectroscopy using 0.1 mmol mesitylene as internal standard.

Scheme 2: Competition reaction between (a) [HBoCb₃] and B(C₆F₅)₃; (b) [HB(C₆F₅)₃] and BoCb₃.

2.6 ppm cf. -9.8 ppm, R = *p*-Cl-C₆H₄ -3.1 ppm cf. -8.6 ppm, R = *p*-F-C₆H₄ -3.7 ppm cf. -9.1 ppm, R = *o*-tol 3.4 ppm cf. -29.7 ppm). The ¹H NMR spectra revealed the hydrogens on the *ortho*-carbon atoms on the carboranes shifted upfield compared to free BoCb₃ (range = 4.60-4.48 ppm cf. 5.02 ppm).

Single crystal X-ray diffraction structures were obtained for [Me₃PSiEt₃][HBoCb₃] and [Ph₃PSiEt₃][HBoCb₃]. In both structures, the central B-H boron sits on a special position with a C₃-axis of symmetry. The C–B–C angles of the central boron are 114.22(12)° and 115.18(12)°, indicating significant distortion from tetrahedral due to the bulky *ortho*-carborane substituents. The B–C bond lengths from the central boron are 1.712(2) Å and 1.703(2) Å, longer than free BoCb₃ [Range = 1.614(8)-1.627(7) Å] (Figure 3).⁷ The borohydride species with B(C₆F₅)₃, [HB(C₆F₅)₃], has a shorter B–C bond [1.641(3) Å cf. HBoCb₃ 1.712(2) Å] and less obtuse C–B–C bond angle [112.09(18)° vs. 114.22(12)° and 115.18(12)° for [HBoCb₃].¹⁶ The longer bond and wider angle are rationalized by the larger steric bulk of *ortho*-carborane versus pentafluorophenyl.

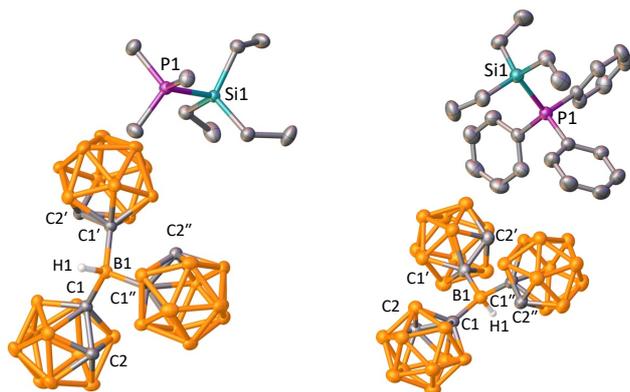

Figure 3: Solid state structures of [Me₃PSiEt₃][HBoCb₃] (left) and [Ph₃PSiEt₃][HBoCb₃] (right). Ellipsoids depicted at the 50% probability level and hydrogen atoms are omitted for clarity. In the two structures, the cations and anions lie on three-fold symmetry sites and the remaining 2/3 of the ions are generated by symmetry. Selected bond lengths (Å) and angles (°): [Me₃PSiEt₃][HBoCb₃]: B(1)–C(1) 1.712(2), P(1)–Si(1) 2.295(13), C(1)–B(1)–C(1') 114.22(12); [Ph₃PSiEt₃][HBoCb₃]: B(1)–C(1) 1.703(2), P(1)–Si(1) 2.359(15), C(1)–B(1)–C(1') 115.18(12).

To determine whether B(C₆F₅)₃ or BoCb₃ bind hydride more readily, a solution of [Ph₃PSiEt₃][HBoCb₃] was stirred with an equivalent of B(C₆F₅)₃ at 23 °C for an hour. There was no indication of hydride transfer from BoCb₃ to B(C₆F₅)₃ to form [HB(C₆F₅)₃] based on ¹⁹F{¹H} and ¹H NMR spectroscopy (Scheme 2). The equimolar reaction of [NEt₄][HB(C₆F₅)₃]¹⁷ and BoCb₃ in CDCl₃ at 23 °C resulted in partial conversion to [HBoCb₃] and B(C₆F₅)₃ based on ¹⁹F{¹H} and ¹H NMR spectroscopy. Adding 1.4 equivalents of [NEt₄][HB(C₆F₅)₃] resulted in full conversion of BoCb₃ to [NEt₄][HBoCb₃]. This is in line with the higher calculated hydride affinity of BoCb₃ (622 kJ/mol cf. 484 kJ/mol).^{7, 10}

To investigate the versatility of the BoCb₃ FLP system, we attempted CO₂ activation. The intermolecular FLP combination of B(C₆F₅)₃ and P^tBu₃ reversibly binds CO₂ via addition across a C=O which is also possible with the ethylene bridged intramolecular FLP Mes₂P(CH₂)₂B(C₆F₅)₂.¹⁸ The exposure of a

C_6D_6 solution of $BoCb_3$ and P^tBu_3 or PMe_3 solution to an atmosphere of CO_2 at 23 °C did not result in any reaction by 1H and ^{11}B NMR spectroscopy. Addition of $HSiEt_3$ to attempt the hydrosilation of CO_2 resulted in no reaction at 23 °C or at 80 °C.

Conclusions

This work discloses that $BoCb_3$ is resistant to forming adducts with a wide variety of bases and generates FLPs. The quenched reactivity could be applied to Si–H bond cleavage with triarylphosphines and trialkylphosphines to generate the phosphoniumsilane and tris(*ortho*carboranyl)borohydride ion pairs, $[R_3PSiEt_3][HBoCb_3]$. In triarylphosphines the bulk in $P(o-tol)_3$ and electron withdrawing nature of $P(p-F-C_6H_4)_3$ required an extra equivalent of silane and $P(C_6F_5)_3$ did not react at all. Notably, in prior work by Gagné, many of these did not react at all with $B(C_6F_5)_3$ and those that reacted required ten equivalents of triethylsilane. In regards to amines, NEt_3 was effective but NPh_3 did not induce any reactivity. The C–B–C bond angle in $[HBoCb_3]$ is more obtuse than in $[HB(C_6F_5)_3]$, consistent with the steric profile. The greater hydride affinity of $BoCb_3$ over $B(C_6F_5)_3$ was experimentally validated by competition studies with the respective hydride salts. These studies clearly indicate that $BoCb_3$ is bulkier and has a higher hydride affinity than $B(C_6F_5)_3$, that bodes well for FLP reactivity beyond Si–H cleavage.

Experimental Section

General considerations: All manipulations were performed under an inert atmosphere in a nitrogen filled MBraun Unilab glove box or using standard Schlenk techniques. Deuterated solvents $CDCl_3$ and C_6D_6 for NMR spectroscopy were purchased from Cambridge Isotope Laboratories, Inc., dried by stirring for 5 days over CaH_2 , distilled, and stored over 3 Å molecular sieves. Deuterated dichloromethane CD_2Cl_2 was purchased from Cambridge Isotope Laboratories, Inc. and used as received. All other solvents were purchased from commercial sources as anhydrous grade, dried further using a JC Meyer Solvent System with dual columns packed with solvent-appropriate drying agents, and stored over 3 or 4 Å molecular sieves. Tris(*ortho*carboranyl)borane and $[NEt_4][HB(C_6F_5)_3]$ were prepared by the literature procedure.^{7, 17} The following reagents: *ortho*carborane, *n*BuLi, 2,6-dimethylphenyl isocyanide, triphenylphosphine, tricyclohexylphosphine, trimethylphosphine, tris(*o*-tolyl)phosphine, tris(4-chlorophenyl)phosphine, tris(4-fluorophenyl)phosphine, tris(pentafluorophenyl)phosphine, triphenylamine, tris(pentafluorophenyl) borane, tetraethylammonium bromide, and triethylsilane were purchased from commercial sources and used without further purification. Ethyl acetate was kept over molecular sieves overnight and distilled. Triethylamine was dried over CaH_2 and distilled before use. Multinuclear NMR spectra (1H , $^{13}C\{^1H\}$, $^{11}B\{^1H\}$, ^{11}B , $^{31}P\{^1H\}$, $^{19}F\{^1H\}$) were recorded on a Bruker Avance III HD 400 MHz or 600 MHz instrument. High Resolution mass spectra (HRMS) were obtained in the Baylor

University Mass Spectrometry Center on a Thermo Orbitrap Q-Exactive spectrometer using +ESI and –ESI. Melting points (m.p.) or decomposition points (d.p.) were measured with a Thomas Hoover Uni-melt capillary melting point apparatus and are uncorrected. FT-IR spectra were recorded on a Bruker Alpha ATR FT-IR spectrometer on solid samples. Single crystal X-ray diffraction data were collected on a Bruker Apex III-CCD detector using Mo- $K\alpha$ radiation ($\lambda = 0.71073$ Å). Crystals were selected under paratone oil, mounted on MiTeGen micromounts, and immediately placed in a cold stream of N_2 . Structures were solved and refined using SHELXTL¹⁹ and figures produced using OLEX2.²⁰

Crystallization of EtOAc- $BoCb_3$: Single crystals of EtOAc- $BoCb_3$ for X-ray diffraction studies were grown from an EtOAc (5 mL) solution of $BoCb_3$ (0.20 mmol, 88.5 mg) by vapor diffusion into toluene (10 mL) at 23 °C. From the crystallization vial, excess ethyl acetate was removed via pipette and the solids were further dried under vacuum to collect the NMR spectroscopic data. Dissolving the crystals of EtOAc- $BoCb_3$ in $CDCl_3$ and acquiring a 1H NMR spectrum did not show a resilient adduct. Titration studies are shown in the spectra section (Figure S1 and S2).

Preparation of 2,6-(CH_3) $_2C_6H_3NC-BoCb_3$: A chloroform solution of 2,6-dimethylphenyl isocyanide (0.21 mmol, 27.9 mg, 5 mL) was added to a chloroform solution of $BoCb_3$ (0.20 mmol, 88.5 mg, 5 mL) at 23 °C. The reaction mixture was stirred for 5 min. The volatiles removed in vacuo and the product crystallized from chloroform/*n*-pentane (3:7 ratio, 10 mL) to give pure 2,6-(CH_3) $_2C_6H_3NC-BoCb_3$ as white solid. Single crystals for X-ray diffraction studies were grown by vapor diffusion of a saturated dichloromethane solution of 2,6-(CH_3) $_2C_6H_3NC-BoCb_3$ into toluene. Yield: 94%, 107.3 mg; dp: 252 °C; 1H NMR (400 MHz, $CDCl_3$): $\delta = 7.51$ (t, $J = 8.0$ Hz, 1H), 7.29 (d, $J = 8.0$ Hz, 2H), 4.72 (s, 3H), 3.12–1.75 (m, 36H) ppm; $^{13}C\{^1H\}$ NMR (101 MHz, $CDCl_3$): $\delta = 139.4$, 134.0, 130.2, 121.9, 64.0, 20.8 ppm; $^{11}B\{^1H\}$ NMR (128 MHz, $CDCl_3$): $\delta = 2.0$ (s), –3.5 (s), –5.1 to –18.0 (m) ppm; ^{11}B NMR: $\delta = 1.9$ (d, $J = 122.9$ Hz), –3.5 (d, $J = 138.2$ Hz), –5.1 to –19.9 (m) ppm; FT-IR (ranked intensity, cm^{-1}): 3141 (7), 2646 (8), 2591 (1), 2563 (10), 2544 (9), 1475 (12), 1131 (11), 1076 (6), 1034 (3), 987 (13), 880 (5), 775 (2), 746 (14), 726 (4), 658(15); HRMS (\pm ESI): a peak corresponding to the adduct was not observed.

General reactions with phosphine and amine Lewis bases (PMe_3 , PPh_3 , PCy_3 , $P(p-Cl-C_6H_4)_3$, $P(o-tol)_3$, $P(p-F-C_6H_4)_3$, NEt_3 , or NPh_3): The Lewis base (0.02 mmol; in 0.2 mL C_6D_6) was added to a solution of $BoCb_3$ (0.02 mmol, 8.8 mg) in C_6D_6 (0.7 mL) at 23 °C and stirred for 1 h. Analyzing the sample by 1H , $^{31}P\{^1H\}$, and $^{19}F\{^1H\}$ NMR spectroscopy did not show any shift from the starting materials.

General procedure for the synthesis of $[LB-SiEt_3][HBoCb_3]$ (LB = Lewis Base) ion pairs: A benzene solution of the Lewis base (2 mL) was added to a benzene solution of $BoCb_3$ (2 mL) followed by the addition of $HSiEt_3$ at 23 °C. The reaction mixture was stirred for 1 h. The precipitate was collected by filtration, washed with benzene (3×1 mL), and dried in vacuo to give the product as a white solid. Amounts and characterization details

for each species are listed as well as any deviations from the general procedure.

[Me₃PSiEt₃][HBoCb₃] PMe₃: 0.045 mmol, 4.6 μ L; BoCb₃: 0.045 mmol, 19.9 mg; HSiEt₃: 0.045 mmol, 7.1 μ L. Single crystals for X-ray diffraction studies were grown from a dichloromethane solution of [Me₃PSiEt₃][HBoCb₃] by vapor diffusion into hexanes. Yield: 80%, 22.8 mg; dp: 156 °C; ¹H NMR (400 MHz, CDCl₃): δ = 4.61 (s, 3H), 2.80-1.47 (m, 39H), 1.21 (t, *J* = 8.0 Hz, 9H), 1.13 (q, *J* = 6.7 Hz, 6H) ppm; ¹³C{¹H} NMR (101 MHz, CDCl₃): δ = 65.0, 8.9 (d, *J* = 37.4 Hz), 7.4, 2.0 (d, *J* = 11.1 Hz) ppm; ¹¹B{¹H} NMR (128 MHz, CDCl₃): δ = -1.4 (s), -4.1 (s), -5.8 to -16.6 (m) ppm; ¹¹B NMR: δ = -1.4 (d, *J* = 133.1 Hz), -4.1 (d, *J* = 149.8 Hz), -5.8 to -16.5 (m) ppm; ³¹P{¹H} NMR (162 MHz, CDCl₃): δ = -25.9 ppm; HRMS (-ESI): calculated for [C₆B₃₁H₃₄]⁻ [M]⁻ 441.5758; found 441.5771.

[Ph₃PSiEt₃][HBoCb₃] PPh₃: 0.24 mmol, 63.7 mg, in 5 mL benzene; BoCb₃: 0.24 mmol, 106.9 mg, in 5 mL benzene; HSiEt₃: 0.24 mmol, 38.8 μ L. Single crystals for X-ray diffraction studies were grown from a dichloromethane solution of [Ph₃PSiEt₃][HBoCb₃] by vapor diffusion into toluene. Yield: 96%, 190.1 mg; dp: 168 °C; ¹H NMR (400 MHz, CDCl₃): δ = 7.89-7.81 (broad, m, 3H), 7.78-7.68 (m, 6H), 7.46-7.41 (m, 6H), 4.60 (s, 3H), 2.81-1.68 (m, 30H), 1.26-1.17 (m, 6H), 1.07 (t, *J* = 8.0 Hz, 9H) ppm; ¹³C{¹H} NMR (101 MHz, CDCl₃): δ = 135.1 (d, *J* = 2.0 Hz), 133.5 (d, *J* = 10.1 Hz), 131.2 (d, *J* = 12.1 Hz), 65.0, 7.7 (d, *J* = 4.0 Hz), 4.8 (d, *J* = 10.1 Hz) ppm; ¹¹B{¹H} NMR (128 MHz, CDCl₃): δ = -1.5 (s), -4.1 (s), -5.6 to -15.7 (m) ppm; ¹¹B NMR: δ = -1.5 (d, *J* = 126.7 Hz), -4.1 (d, *J* = 134.4 Hz), -5.9 to -16.8 (m) ppm; ³¹P{¹H} NMR (162 MHz, CDCl₃): δ = -2.9 ppm; FT-IR (ranked intensity, cm⁻¹): 3131 (14), 2552 (3), 1730 (7), 1602 (10), 1439 (5), 1331 (15), 1235 (8), 1161 (12), 1112 (13), 1072 (2), 1034 (11), 885 (6), 724 (1), 682 (9), 493 (4). HRMS (-ESI): calculated for [C₆B₃₁H₃₄]⁻ [M]⁻ 441.5758; found 441.5773.
