DOI: 10.1039/b000000x

Sequence catalysis merging photoredox catalysis (PC) and nucleophilic catalysis (NC) has been realized for the direct sp^3 C-H acroleination of *N*-aryl-tetrahydroisoquinoline (THIQ).

¹⁰ The reaction was performed under very mild conditions and afforded products in 52-93% yields. A catalytic asymmetric variant was proved to be successful with moderate enantioselectivities (up to 83:17 e.r.).

The development of efficient and sustainable processes to construct new C-C bonds has attracted remarkable attention from chemical community.¹ From the viewpoint of green catalysis, visible light photoredox catalysis (PC) is an ideal complement to the conventional thermal procedures.^{2,3} Particularly, sequence catalysis by merging PC with other catalytic models has become extremely powerful in direct functionalizations of inert C-H bonds.^{4,5} Pioneered by the Stephenson group,⁶ *N*-aryl-tetrahydroisoquinoline (THIQ) has been widely employed as the

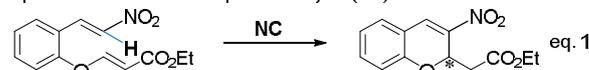

Scheme 1. Representative examples of functionalization of C-H bonds of THIQ via PC-based dual catalysis.

testing platform⁵ to verify the feasibility of sequence catalysis (Scheme 1).⁷ Notably, Rueping and co-workers have developed direct Mannich reactions of THIQs with methyl ketones by integrating PC with enamine catalysis.^{5g} Since then, sequence catalysis combining PC and *N*-heterocyclic carbene (NHC) catalysis,^{5d} H-bonding catalysis^{5a} and transition metal catalysis^{5e,5f} have been successfully developed by the groups of

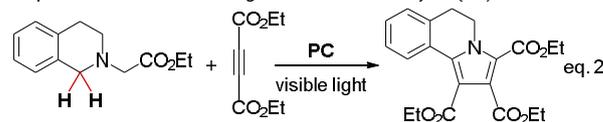

Roivis, Rueping, Stephenson and Jacobsen, respectively, to install carbonyls, alkynyl or methyl esters moiety to C-H bonds adjacent to *N*-atom. Despite these impressive advances, sequence catalysis involving visible light photoredox catalysis has not achieved its full potential.

Over the past decades, nucleophilic catalysis (NC) has grown at a dramatic pace in C-C formation reactions.⁸ Encouraged by our success of both NC (eq. 1)⁹ and PC (eq. 2)¹⁰, we recently questioned whether it might be possible to merge these two powerful catalytic models, with the goal of direct functionalization of inactive C-H bonds. Inspired by elegant work from the Wang group on tertiary amine/copper co-catalysed oxidative olefination reaction of THIQ,¹¹ we chose the same transformation to test our proposal. The challenge is the compatibility of nucleophilic catalyst under PC conditions since traditional nucleophilic catalysts (i.e. DABCO and PPh₃) might be oxidized in the presence of oxidative radicals (*vide infra*).

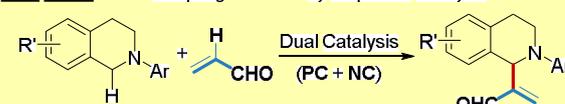

Our previous work on Nucleophilic Catalysis (NC):

Our previous work on visible light Photoredox Catalysis (PC):

This work: Cross Coupling Reaction by sequence catalysis

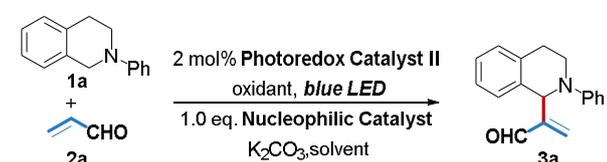

•Challenge: the compatibility of NC with PC condition.

The acroleination of sp^3 C-H bonds of THIQs was evaluated by using *N*-phenyl tetrahydroisoquinoline **1a** and acrolein **2a** as the substrates in the presence of different nucleophilic catalysts, photocatalysts, and oxidants (Table 1). It was found that oxidized isoquinoline, 2-phenyl-3,4-dihydroisoquinolin-1(2*H*)-one, was isolated as the major product when Ru(bpy)₃Cl₂·6H₂O (**I**) was employed as the photoredox catalyst and oxygen was used as the oxidant (Table 1, entry 1). To our delight, the proposed acroleination reaction did proceed when BrCCl₃ was introduced

as the oxidant (Table 1, entry 2: 49% yield). To address the compatibility of nucleophilic catalysts with photoredox catalysts and oxidants, we examined the stoichiometric reaction of nucleophilic catalysts, DABCO and PPh₃, with BrCCl₃ under PC conditions. The results indicated that DABCO decomposed completely in the presence of BrCCl₃ under irradiation of blue light, but remains unchanged without blue light. In addition, PPh₃ disappears quickly with or without the blue light irradiation. Thus, one-pot operation was applied to the designed reaction: **1a** was mixed with BrCCl₃ and Ru(bpy)₃Cl₂·6H₂O (**I**) to generate the iminium intermediates *in situ* under PC conditions, and then DABCO, acid acceptor (K₂CO₃) and **2a** were added to the reaction mixture after removing blue LED irradiation.^{5a,5f} To our delight, by this manipulation an increased yield of product **2a** was achieved (75% yield, Table 1, entry 3). In addition, the effect of different photosensitizers and nucleophilic catalysts was explored, and the results showed that the combination of Ir(ppy)₂(dtbbpy)PF₆ (**II**) and DABCO was the best (Table 1, entries 4-8). To further improve the reaction efficiency, different reaction media were screened. As presented in Table 1, the reaction was applicable with a variety of different solvents such as MeCN, THF, DCM, and DMSO (entries 9-13). The use of mixed solvent (DMSO:DCM= 1:1) gave the best result (83% yield, Table 1, entry 13)¹².

Table 1. Optimization of reaction conditions^a

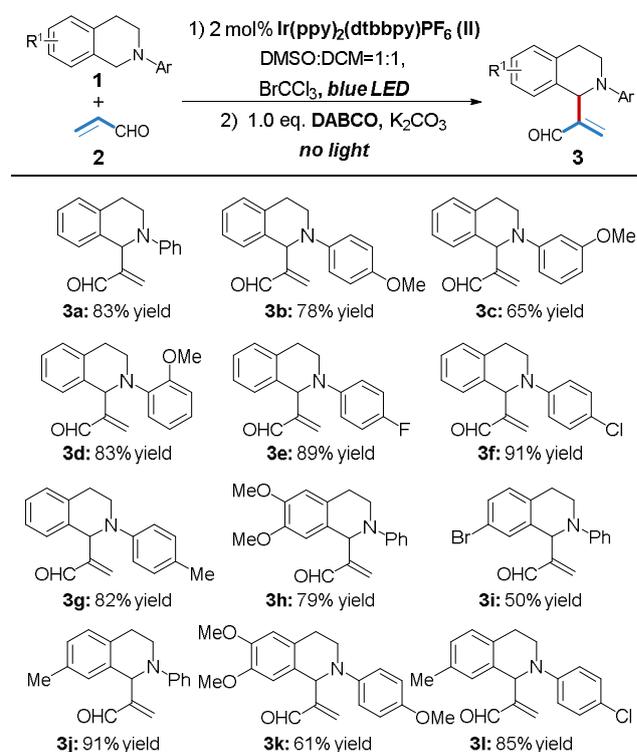

| Entry | Photoredox Catalyst | Nucleophilic Catalyst | Oxidant | Solvent | Yield (%) ^b |
|----------------|-------------------------|-----------------------|--------------------|--------------|------------------------|
| 1 | I | DABCO | O ₂ | DMF | n.d. |

^a Reaction conditions: **1a** (0.5 mmol), Photoredox Catalyst (2 mol%), BrCCl₃ (3.0 equiv) in solvent (2 mL), blue LED irradiation at r.t., 3h, then *no light*, **2a** (5.0 equiv.), Nucleophilic Catalyst (1.0 equiv.), K₂CO₃ (1.0 equiv.). ^b Yield of isolated product. ^c Reaction conditions: **1a** (0.5 mmol), Photoredox Catalyst (2 mol%), **2a** (5.0 equiv.), Nucleophilic Catalyst (1.0 equiv.), K₂CO₃ (1.0 equiv.) and oxygen (1 atm) or BrCCl₃ (3.0 equiv.) in DMF (2 mL) under blue LED irradiation at r.t.. ^d Esion Y (**III**). ^e Ru(bpy)₃PF₆ (**IV**).

Under the optimal reaction conditions, the scope of *N*-substituted THIQs for this acroleination reaction was next

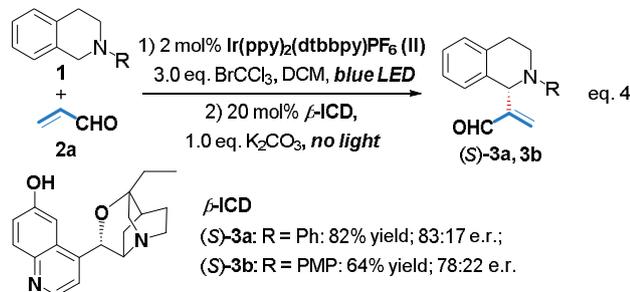

examined. The electronic nature of the aromatic substituents on the nitrogen atom shows no pronounced effect on the overall reaction outcomes. As highlighted in Table 2, substrates bearing an electron-donating (*p*-OMe) or electron-withdrawing group (*p*-F) on the phenyl rings participate in this transformation efficiently (**3b**: 78% yield, **3e**: 89% yield). Moreover, this acroleination reaction tolerated the *o*-OMe group well (**3d**: 83% yield), which did not show a steric hindrance for the addition step. Though an undetermined by-product was isolated from the resultant mixture in the case of *m*-OMe substituted substrate **1c**, the desired product was still obtained in a good isolated yield (**3c**: 65% yield). Incorporation of chloro and methyl substituents at the *para*-position of *N*-phenyl group is possible without loss in reaction efficiency (**3f**: 93% yield; **3g**: 82% yield). Perhaps more importantly, significant structural variation on the tetrahydroquinonine scaffold can also be realized. A variety of substituents can be successfully incorporated on the THIQ at different positions (**3h**: 79% yield, **3i**: 52% yield, **3j**: 91% yield, **3k**: 57% yield and **3l**: 81% yield). Notably, when acrylonitrile was used instead of acrolein, the reaction could also proceed well and the desired product was obtained in 65% yield (eq. 3).

Table 2. Substrate scope^a

^a Reaction conditions: **1** (0.5 mmol), Ir(ppy)₂(dtbbpy)PF₆ (**II**) (2 mol%), BrCCl₃ (3.0 equiv) in solvent (2 mL), blue LED irradiation at r.t., 3h, then *no light*, **2** (5.0 equiv.), DABCO (1.0 equiv.), K₂CO₃ (1.0 equiv.).

A catalytic asymmetric acroleination has been carried out by using a chiral nucleophilic catalyst. With the use of 20 mol% β -isocupreidine (β -ICD) as the nucleophilic catalyst, the reaction afforded the enantioenriched (*S*)-**3a** and (*S*)-**3b** (eq. 4, **3a**: 82% yield, 83:17 e.r.; **3b**: 64% yield, 78:22 e.r.), respectively.

Conclusions

In summary, we have developed the first example of sequence catalysis by merging visible light photoredox catalysis and nucleophilic catalysis. This process is able to directly assemble acrolein to the sp^3 C-H at the α -position of tertiary amine in moderate to excellent yields (52-93%). The primary trial on catalytic asymmetric acroleination of THIQ was realized with moderate enantioselectivity.

Graphic Abstract:

Sequence catalysis by merging visible light photoredox catalysis (PC) with nucleophilic catalysis (NC) has been realized for the first time for the direct sp^3 C-H acroleination of tertiary amines (50-91% yields). Catalytic asymmetric variant was performed successfully with significant enantioselectivity.
