

Analytical Methods

Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

27
28 11 **Abstract**

29
30 12 Gas chromatographic (GC) determination of 9 guanidino compounds: guanidine,
31
32 13 methylguanidine, guanidinoacetic acid, guanidinopropionic acid, guanidinobutyric acid,
33
34 14 guanidinosuccinic acid, arginine, creatinine and creatine have been examined from the
35
36 15 serum and urine of healthy volunteers and uremic patients using precolumn derivatization
37
38 16 with methylglyoxal and ethyl chloroformate. GC elution and separation was from the
39
40 17 column HP-5 (30m × 0.32mm id) with film thickness 0.25 μm within 10.5 min. The
41
42 18 detection was carried out using FID. The linear calibration curves for guanidino
43
44 19 compounds were within 0.1 – 20.0 μmol L⁻¹ and lower limits of detection were 0.014 -
45
46 20 0.027 μmol L⁻¹. The amounts of guanidino compounds observed in the serum of healthy
47
48 21 volunteers were 0.2 - 88.0 μmol L⁻¹ as compared to uremic patients 0.8 - 521 μmol L⁻¹
49
50 22 with relative standard deviations (RSD) within 1.5 - 3.7% and 1.0 - 3.8% respectively.
51
52 23 The guanidino compounds in the urine of healthy volunteers and uremic patients were
53
54
55
56
57
58
59
60

1
2
3
4 24 observed in the range below the limit of detection to (BLOD) 7304 $\mu\text{mol L}^{-1}$ and below
5
6 25 LOD - 7541 $\mu\text{mol L}^{-1}$ with RSD 1.1 - 3.7% and 1.0 - 3.8% respectively. The
7
8 26 derivatization, separation and quantitation were repeatable with RSD < 4 %. Recovery of
9
10 27 the guanidino compounds calculated by standard addition from serum and urine was
11
12 28 obtained within 93 - 105% and 89 - 99% with RSD 1.4 - 2.9% and 1.8 - 4.3%
13
14 29 respectively.

15
16
17 30 Key words: GC, Guanidino compounds, methylglyoxal, ethyl chloroformate, uremic
18
19 31 patients, healthy volunteers, serum, urine.

22 32 **Introduction**

23
24 33 Guanidino compounds are present in the biological fluids and provide information about
25
26 34 renal function. Their concentration is reported to increase in the uremic patients and some
27
28 35 of these are considered as uremic toxins^{1,2}. Methylguanidine (MG) is related to uremic
29
30 36 polyneuropathy³. Guanidinosuccinic acid (GSA) is reported for uremic bleeding
31
32 37 diathesis⁴. GSA, MG, guanidine (G) and creatinine (CTN) are reported to cause chronic
33
34 38 and generalized seizures after systematic and intracerebroventricular administration in
35
36 39 mice^{5,6}. Several guanidino compounds are shown to affect leukocyte activity and
37
38 40 homocysteine protein binding, possibly resulting in cardiovascular disease, which is one
39
40 41 of the major cause of mortality in patients with chronic renal disease^{7,8}. The concentration
41
42 42 of GSA is reported to decrease in serum and urine of cirrhotic patients⁹ and concentration
43
44 43 of GAA is increased in the abnormality in the guanidinoacetate methyltransferase
45
46 44 deficiency^{10,11}.

47
48
49 45 The analyses of guanidino compounds have clinical importance. They are present
50
51 46 in biological fluids at low concentration and they do not contain strong chromophore and
52
53
54
55
56
57
58
59
60

1
2
3 47 fluorophore groups. Pre or post HPLC column derivatization is generally carried for the
4
5 48 sensitive spectrophotometric and fluorometric detection. A number of derivatizing
6
7
8 49 reagents have been proposed for HPLC determination of guanidino compounds mainly
9
10 50 benzoin¹²⁻¹⁴, ninhydrin^{15,16}, 9,10-phenanthrenequinone¹⁷, anisoin¹⁸, furoin¹⁹ and
11
12 51 pyridoin²⁰.

13
14
15 52 Gas chromatography has high potential for the separation of organic compounds
16
17 53 with low running cost and analysis could be completed with short running time. The GC
18
19
20 54 of guanidino compounds has been carried out after precolumn derivatization with
21
22 55 trifluoroacetic anhydride²¹, hexafluoroacetylacetone²², hexafluoroacetylacetone-mono
23
24 56 (trimethylsilyl) trifluoroacetamide^{23,24}, hexafluoroacetylacetone pentafluorobenzyl
25
26
27 57 bromide²⁵, hexafluoroacetylacetone and ethyl chloroformate²⁶. High sensitivity has been
28
29 58 reported by using GC-MS, but requires reaction time (> 2h at 80 °C) and a limited
30
31
32 59 number of guanidino compounds (2-6 compounds) have been reported and determined²³⁻
33
34 60 ²⁵. Recently glyoxal and glyoxal-ethyl chloroformate have been used for the separation
35
36
37 61 and determination of 6 guanidino compounds²⁷⁻²⁸.

38
39 62 Methylglyoxal (MGo) is an endogenous metabolite²⁹ and is known as precursor of
40
41 63 advanced glycation end products (AGEs)^{30,31}, which accumulates in the plasma of
42
43 64 diabetic and uremic patients^{32,33}. Methylglyoxal is identified to react with guanidino
44
45
46 65 group in proteins^{29, 34} and the reaction have been shown to occur at physiological
47
48 66 concentrations of methylglyoxal^{35,36}.

49
50
51 67 MGo is reported to react with guanidino compounds to form imidazolone
52
53 68 adducts^{27,36} and binds two imino nitrogens of guanidine groups, but the molecules still
54
55
56 69 contain free carboxylic acid or imine groups. Ethyl chloroformate (ECF) is reported to
57
58
59
60

1
2
3 70 react with carboxylic acid and imine groups quickly in aqueous-organic phase to form
4
5 71 derivatives amiable to GC³⁷⁻³⁹. The present work examines the use of MGo and ECF as
6
7
8 72 precolumn derivatizing reagents for GC elution, separation and determination of the
9
10 73 guanidino compounds from biological fluids (serum and urine). Experimental conditions
11
12 74 for derivatization, GC elution and separation are optimized before determinations.

15 75 **Experimental**

17 76 **Chemicals and Solutions**

19
20 77 Methylglyoxal (MGo) (40% solution), ECF (Fluka, Buchs, Switzerland), guanidine (G),
21
22 78 methylguanidine (MG), guanidinoacetic acid (GAA), guanidinopropionic acid (GPA),
23
24 79 arginine (Arg), creatinine (CTN), creatine (CT) (Sigma Aldrich, St. Louis, MO, USA),
25
26 80 guanidinobutyric acid (GBA) (Sigma Aldrich, Buchs, Switzerland), guanidinosuccinic
27
28 81 acid (GSA) (Sigma Aldrich Chemie, GmbH, Mannheim , Germany), methanol (RDH
29
30 82 Chemicals Co. Spring Valley CA, USA), chloroform (LAB-SCAN, Bangkok, Thailand),
31
32 83 guaranteed reagent grade potassium hydroxide, hydrochloric acid (37%), potassium
33
34 84 chloride, acetic acid, sodium acetate, ammonium acetate, sodium tetraborate, boric acid,
35
36 85 sodium bicarbonate, ammonium chloride and ammonia solution from E-Merck,
37
38 86 Darmstadt, Germany were used.

39
40
41 87 The stock solutions of guanidino compounds containing 1000 $\mu\text{mol/L}$ were
42
43 88 prepared in water containing few drops of hydrochloric acid (1 M). Other solutions were
44
45 89 prepared by appropriate dilution. 2,3-dimethyl-5,6-diphenyl-5,6-dihydropyrazine was
46
47 90 used as internal standard and was prepared as reported²⁷ by refluxing together equimolar
48
49 91 dimethylglyoxal with meso-stilbenediamine in methanol for 30 min.
50
51
52
53
54
55
56
57
58
59
60

1
2
3 92 Buffer solutions (0.1M) between pH 1 - 10 at unit interval were prepared from the
4
5 93 following: potassium chloride adjusted with hydrochloric acid (pH 1 - 2), acetic acid and
6
7
8 94 sodium acetate (pH 3 - 6), ammonium acetate (pH 7), boric acid and sodium tetraborate
9
10 95 (pH 8 - 9), sodium bicarbonate – sodium carbonate (pH 9) and ammonium chloride –
11
12 96 ammonia (pH 10).

15 97 **Equipment**

17 98 The pH measurements were made with an Orian 420A pH meter with combined glass
18
19 99 electrode and reference internal electrode. IR spectrum of internal standard was recorded
20
21 100 on an Avatar 330 FT-IR (Thermo Nicolet, Thermo Electron Corporation, USA) with
22
23 101 attenuated total reflectance (ATR) (accessory Smart Partner) within a range of 4000 - 600
24
25 102 cm^{-1} . Gas chromatographic studies were carried out on Agilent model 6890 network GC
26
27 103 system (Agilent Technology Inc. USA), split injector, flame ionization detection (FID),
28
29 104 hydrogen generator (Parker Balston Analytical Gas System, Parker Hannifin Havorhill,
30
31 105 MA, USA) and pure nitrogen (British Oxygen Company, Karachi). The computer with
32
33 106 Chemstation Software controlled the gas chromatograph. A capillary column HP-5 (30 m
34
35 107 \times 0.32 mm id) with layer thickness of 0.25 μm (J & W Scientific Corporation, USA) was
36
37 108 used throughout the study.

43 109 **Synthesis of Imidazolone Derivative of GBA and CTN**

44 110 The solution of GBA or CTN (0.001M) in methanol – water (1:1 v/v) was added MGo
45
46 111 (0.001M) in methanol. The contents were refluxed for 1 h. The reaction mixture turned
47
48 112 from colourless to red during heating. The product was allowed to cool at room
49
50 113 temperature and solvent was removed under reduced pressure. The oily mass obtained
51
52 114 was washed several times with ether and n-hexane. Semi solid product obtained was
53
54
55
56
57
58
59
60

1
2
3 115 dried at 80 °C. The mass spectra of the derivatives were recorded at HEJ Research
4
5 116 Institute of Chemistry, University of Karachi, on Jeol MS Route using direct probe intel
6
7
8 117 and E1+ ionization mode. GBA derivative indicated main peaks at m/z (rel. intensity %)
9
10 118 196 (8.4), 180 (11.9), 152 (15), 138 (18.7), 124 (84.1), 110 (11.5) and 44 (100), FT-IR
11
12 119 cm⁻¹ at 1667, 1652, 1453, 1387, 1330, 1298, 1217, 1147, 1098, 1003 and 926. CTN
13
14 120 derivative indicated main peaks at m/z (rel. intensity %) 166 (12.2), 139 (31.2), 111
15
16 121 (15.5), 83 (11.1), 69 (19.5) and 44 (100). FT-IR cm⁻¹ at 1672, 1589, 1122, 1095, 1088,
17
18 122 1076, 1067, 822, 795, 785 and 776.
19
20
21

22 **Analytical Procedure**

23
24
25 124 To the guanidino solution 0.3 mL adjusted to 1 mL with distilled water (0.67 - 66.67
26
27 125 μmol L⁻¹) in 5 mL screw capped vial was added sodium tetraborate buffer pH 7.5 (0.3
28
29 126 mL), MGo (3% in methanol v/v) (0.3 mL) and 2,3-dimethyl-5,6-diphenyl-5,6-
30
31 127 dihydropyrazine (33.33 μmol/L) (0.3 mL) as internal standard. The contents were
32
33 128 warmed on water bath at 80 °C for 15 min and allowed to cool at room temperature (5
34
35 129 min). To this solution was added carbonate buffer (pH 9) (0.3 mL) and ECF (0.3 mL) and
36
37 130 the contents were sonicated for 10 min. Chloroform (1 mL) was added and contents were
38
39 131 mixed well. The layers were allowed to separate and an aliquot of the organic layer was
40
41 132 transferred to a septum capped sample vial. The solution (1 μL) was analyzed on column
42
43 133 HP-5 using a temperature program 80 °C for 3 min, followed by heating rate 20 °C min⁻¹
44
45 134 up to 270 °C; total run time was as 13 min. Nitrogen flow rate was 2.5 mL min⁻¹ with
46
47 135 split ratio 10:1. The injector and detector temperatures were fixed at 270 °C and 280 °C
48
49 136 respectively. The flow rates for FID were fixed 45 mL min⁻¹ for nitrogen as make up gas
50
51 137 40 mL min⁻¹ hydrogen and 450 mL min⁻¹ for air.
52

56
57
58
59
60

138 **Sample Collection and Pretreatment**

139 The blood and urine samples of uremic patients with verbal / written consent were
140 obtained from Liaquat University of Medicine and Health Sciences Hospital, Jamshoro.
141 The blood samples were collected by vein puncture with hypodermic syringe and were
142 transferred to EDTA tubes. Urine samples were collected in the morning in clean plastic
143 bottle. The blood and urine samples of healthy volunteers were collected with verbal /
144 written consent from the students and employees of Institute of Advanced Research
145 Studies in Chemical Sciences, who had not taken any medicine at least during preceding
146 week. All the donors of the blood and urine samples were informed about the objects of
147 the research project and they agreed to participate in the project. The experimental work
148 permed with the approval of ethical committee of University of Sindh.

149 **Analysis of Guanidino Compounds from Serum**

150 The blood sample (2 mL) collected from healthy volunteers and uremic patients
151 was kept at room temperature (30 °C) for 1h and centrifuged at 3000 g for 30 min. The
152 supernatant layer of the serum was separated and was added methanol (2 mL). The
153 contents were mixed well and again centrifuged at 3000 g for 20 min. The supernatant
154 layer was collected³⁷. The deproteinized serum 1 mL was transferred to screw capped vial
155 and the derivatization and GC analysis was carried out using analytical procedure. The
156 quantitation was carried out using external linear calibration curves using linear
157 regression equation $Y = ax + b$.

158 **Analysis of Serum Using Linear Calibration with Spiked Sample**

159 The blood sample (5 mL) collected from healthy volunteers and uremic patients
160 was treated as above procedure. Four aliquots of (1 mL) of serum from the supernatant

1
2
3 161 layer after deproteinization with methanol was collected. Three serum samples (1 mL)
4
5 162 was added to a mixture of G, MG, GAA, GPA, GBA, GSA, Arg, CTN and CT (0.3 mL)
6
7
8 163 containing 5.0, 15.0 or 33.33 $\mu\text{mol L}^{-1}$ each and all the four solutions were processed by
9
10 164 analytical procedure. The quantitation was carried out by recording the responses
11
12 165 (average peak height / peak area ($n = 3$) against the standard added and measuring the
13
14
15 166 concentration at $y = 0$. The quantitation was also carried out from the increase in the
16
17
18 167 response from the calibration curve with the added standards.

19 168 **Analysis of Urine Samples**

20
21
22 169 Urine sample (5 mL) collected from healthy volunteers and uremic patients was
23
24 170 added methanol (5 mL) and was centrifuged for 30 min at 3000 g. The supernatant layer
25
26
27 171 was collected. 1 mL of deproteinized urine was diluted to 5 mL with distilled water and 1
28
29 172 mL of diluted sample was taken and processed by analytical procedure. The quantitation
30
31
32 173 was made by external calibration and from the ratio of the peaks using internal standard.

33 174 **Analysis of Urine Using Linear Calibration with Spiked Sample**

34
35
36 175 The urine sample (5 mL) collected from uremic patient was treated as above
37
38
39 176 procedure. Four aliquots (1 mL) of urine from the supernatant layer after dilution and
40
41 177 deproteinization with methanol were collected. Three urine samples (1 mL each) were
42
43 178 added to a mixture of G, MG, GAA, GPA, GBA, GSA, Arg, CTN and CT (0.3 mL)
44
45
46 179 containing 5.0, 15.0 or 33.33 $\mu\text{mol L}^{-1}$ each and the solutions were processed by
47
48 180 analytical procedure. The quantitation was carried out from the increase in the response
49
50
51 181 from the calibration curve with the added standards and recording the average responses
52
53 182 ($n = 3$) against standard added and measuring the concentration at $y = 0$.

54 183 **Results and Discussion**

1
2
3 184 The guanidino compounds are reported to react with methylglyoxal to form
4
5 185 imidazolone adducts^{29,38}. Expected chemical reaction of guanidino compounds with
6
7
8 186 derivatizing reagents (MGo and ECF) is given in **Fig1**. An attempt was made to prepare
9
10 187 pure imidazolone adducts by reaction of equimolar amounts of guanidino compounds and
11
12 188 MGo in methanol – water. The reaction mixture quickly changed to red solution. The
13
14 189 coloured adduct of GBA and CTN were examined for MS. The MS of GBA derivative
15
16 190 indicated peaks at m/z 197 and 180 corresponding to (M-OH)⁺ and (M-COOH)⁺,
17
18 191 respectively. This was followed by fragment peaks at m/z 152, 138 and 124
19
20 192 corresponding to the successive loss of –CH₂ groups. The signals obtained at m/z 124
21
22 193 corresponding to C₅H₆N₃O with relative intensity of 84.1% supports the formation of
23
24 194 imidazolone ring. Base peak (100%) was obtained at m/z 44 corresponding to CO₂
25
26 195 contributed from carboxylic group (**Fig 2**). FT-IR indicated bands at 1667 cm⁻¹ and 1652
27
28 196 cm⁻¹ for ν C=O and C=N respectively and supported the earlier investigators and the
29
30 197 structures assigned^{29,36,38} (**Fig 3**). Similarly MS of CTN derivative indicated peaks at m/z
31
32 198 166 corresponding to (M-OH)⁺ following by peak at m/z 139.1 due to opening of a ring
33
34 199 and loss of fragment corresponding to C₂H₃. A fragment corresponds to C=O is further
35
36 200 lost with observation of peak at m/z 111 corresponding to CTN molecule with loss of two
37
38 201 hydrogen [CTN-2H]⁺. FT-IR also indicated peaks at 1672 and 1589 cm⁻¹ indicating the
39
40 202 presence of C=O and C=N groups within the derivatized molecule.
41
42
43
44
45
46
47

48 203 It was initially observed that guanidino compounds without derivatization did not
49
50 204 elute from GC column, but when excess of MGo was added to the guanidino compounds
51
52 205 at pH 7.5 and the product was allowed at room temperature (30 °C) for 30 min, GC
53
54 206 elution corresponding to guanidino compounds was observed, which separated from the
55
56
57
58
59
60

1
2
3 207 elution of the derivatizing reagent MGo. It was therefore the effect of reaction conditions
4
5 208 were examined in terms of pH, amount of reagent (MGo) to be added per determination
6
7
8 209 and warming time and temperature for the quantitation of guanidino compounds. The
9
10 210 reaction was monitored by measuring average peak height or peak area ($n = 3$) and the
11
12 211 condition which gave maximum response was considered optimum. The effect of pH was
13
14 212 examined within 1 - 10 at unit interval and optimal response was obtained at pH 7 to 8
15
16 213 and pH 7.5 was selected. The addition of the derivatizing reagent MGo (3% v/v) was
17
18 214 varied from 0.1 - 1.0 ml at an interval of 0.1 mL and it was observed that same response
19
20 215 was obtained by the addition of 0.2 mL and above and 0.3 mL was selected per
21
22 216 determination. The reaction required longer time for completion at room temperature,
23
24 217 thus the warming of the reaction within 50 - 100 °C at an interval of 10 °C and warming
25
26 218 time within 5 - 30 min at an interval of 5 min was examined. The warming at 80 °C for
27
28 219 15 min was selected.

29
30
31
32
33
34 220 At the optimized conditions the guanidino compounds G, MG, GAA, GPA, GBA,
35
36 221 GSA, Arg, CTN and CT eluted and separated from the GC column, but to enhance the
37
38 222 sensitivity and selectivity of the analytical procedure, the second derivatization with ECF
39
40 223 was examined. An increase in the sensitivity in terms of increase in peak height / peak
41
42 224 area for 10 – 20% was observed with an improvement in peak shape. It was therefore the
43
44 225 conditions for second derivatization were examined. The effect of pH on second
45
46 226 derivatization with ECF was examined within 6 – 10 at unit interval and maximum
47
48 227 response was at pH 9 using carbonate buffer as has been reported for reactions with
49
50 228 ECF³⁷. The volume of buffer added per analysis was changed from 0.1 to 1.0 mL at an
51
52 229 interval of 0.1 mL and change in the volume of buffer did not have effect on the average

60

1
2
3 230 response ($n = 4$) and volume of buffer was fixed to 0.3 mL. The addition of derivatizing
4
5 231 reagent ECF was varied from 0.1 to 0.6 mL at an interval of 0.1 mL, but no change in
6
7
8 232 peak height was observed by changing its volume and addition of 0.3 mL ECF per
9
10 233 analysis was considered optimum. Chloroform, tertiary butanol, 1,2-dichloroethane and
11
12 234 ethyl acetate were examined as solvents for the extraction of the derivatives. Chloroform
13
14 235 indicated better extraction and was selected for the study. The conditions for GC elution
15
16
17 236 and separation of the guanidino compounds from column HP-5 were examined. Each of
18
19 237 the compounds gave a single peak and separated from the derivatizing reagents. Different
20
21 238 temperature elution programs and nitrogen flow rates were examined for the separation of
22
23 239 the guanidino compounds within short time. Finally initial column temperature of 80°C
24
25 240 for 3 min was fixed, followed by heating rate of 20°C / min up to 270°C with nitrogen
26
27
28 241 flow rate of 2.5 mL / min. Total run time was 11.0 min with split ratio 10:1. All the nine
29
30 242 guanidino compounds plus derivatizing reagent, and internal standard separated
31
32 243 completely (**Fig 4 b**). Peak identification was based on retention time and by spiking of
33
34 244 each of the guanidino compound in the sequence. The derivatives formed were examined
35
36
37 245 after different intervals of the time and it was observed that the derivatives once formed
38
39 246 were highly stable and did not show any change in peak height / peak area or retention
40
41 247 time up to 12 h, with RSD within 5% ($n = 6$). The order of elution for derivatives of the
42
43 248 compounds was (1) derivatizing reagents (2) G, (3) MG, (4) CTN, (5) GAA, (6) GPA, (7)
44
45 249 CT, (8) GBA, (9) Arg, (10) GSA and (11) internal standard (2,3-dimethyl-5,6-diphenyl-
46
47 250 5,6-dihydro pyrazine).

53 251 **Quantitation**

54
55
56
57
58
59
60

1
2
3 252 Linear calibration curves were observed by recording average peak height or peak
4
5 253 area ($n = 4$) versus concentration within 0.1 - 20.0 $\mu\text{mol L}^{-1}$ with coefficient of
6
7
8 254 determination (r^2) within 0.9973 - 0.9997 for each of the guanidino compound using 11
9
10 255 calibrators ($n = 11$). Similarly linear calibrations were also obtained by recording ratio of
11
12 256 average peak height or peak area ($n = 4$) to the internal standard within the same
13
14
15 257 concentration range (0.1 - 20.0 $\mu\text{mol L}^{-1}$). The limit of detection (LOD) and limit of
16
17 258 quantitation (LOQ) measured as signal to noise ratio (3:1) and (10:1) were obtained
18
19 259 within 0.014 - 0.027 $\mu\text{mol L}^{-1}$ and 0.042 - 0.081 $\mu\text{mol L}^{-1}$ respectively (**Table 1**). The
20
21 260 analysis of test mixtures of guanidino compounds within the calibration range indicated
22
23
24 261 relative error within $\pm 2.5 - 5.0\%$.

262 **Precision**

263 Repeatability of GC separation ($n = 6$) was examined in the terms of retention
264 time and peak height and relative standard deviation (RSD) was obtained within 2.5 – 3.9
265 % and 1.7 – 4.3 % respectively. The derivatization, GC separation and quantitation was
266 repeatable in terms of retention time and peak height or peak area for each of the
267 guanidino compound inter ($n = 5$) and intra day ($n = 5$) by the same operator on the same
268 day and different days at a concentration 10 $\mu\text{mol/L}$ and RSD did not increase more than
269 4.0%.

270 The pharmaceutical additives methylparaben, propylparaben, gum acacia,
271 manitol, lactose, fructose, glucose, galactose, sodium chloride, sodium lauryl sulphate
272 and methyl hydroxypropyl cellulose were added twice the concentration of guanidino
273 compound and analysis was carried out following analytical procedure. The results
274 obtained were compared with guanidino compounds standards. The additives did not

1
2
3 275 affect the determination of guanidino compounds with relative error within 4.3 - 5.0%.
4
5 276 The pharmaceutical preparations metformin, ranitidine, cimetidine and famotidine
6
7
8 277 reported to elute from GC column after derivatization with MGo⁴⁰, were examined for
9
10 278 possible interference of the guanidino compounds. The GC elution of the pharmaceutical
11
12 279 preparations were examined at the optimized GC conditions for the guanidino
13
14 280 compounds and it was observed that the pharmaceutical preparations eluted after
15
16 281 guanidino compounds and did not interfere the determination of guanidino compounds.
17
18
19

20 282 **Sample Analysis**

21
22 283 MGo is an endogenous product and is reported to be present in serum and urine of
23
24 284 healthy and uremic patients at the concentration of 0.04 – 0.29 $\mu\text{g mL}^{-1}$ ²⁹. It was
25
26 285 therefore the serum and urine sample was processed without addition of the derivatizing
27
28 286 reagent MGo. No significant response for the guanidino compounds was observed above
29
30 287 LOD and it was considered as blank (**Fig. 4 a**). Blood and urine samples of healthy
31
32 288 volunteers and uremic patients were analyzed for the contents of guanidino compounds.
33
34 289 Sixteen blood samples of healthy volunteers with ages 24 to 28 years were analyzed (**Fig.**
35
36 290 **4 c**). The amounts in $\mu\text{mol L}^{-1}$ found were in the range GSA 1.1 - 1.4, GAA 0.9 - 1.5,
37
38 291 GPA 0.17 - 0.3, CTN 82 - 86, GBA 0.1 - 0.29, Arg 30 - 35, G 0.1 - 0.28, MG 0.3 - 0.41
39
40 292 and CT 33 – 48 with RSDs within 1.5 – 3.7%. Similarly blood samples of 12 uremic
41
42 293 patients within the age of 52 - 60 years were analyzed and amounts of guanidino
43
44 294 compounds $\mu\text{mol L}^{-1}$ were found within GSA 7.5 - 8.1, GAA 4.5 - 5.0, GPA 0.8 - 1.1,
45
46 295 CTN 433 - 502, GBA 0.8 - 1.4, Arg 85 - 90, G 2.7 - 4.0, MG 1.8 - 2.1 and CT 38 - 48
47
48 296 with RSDs within 1.0 – 3.8% (**Table 2**).
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 297 Sixteen urine samples of healthy volunteers within the age of 24 - 28 years were
4
5 298 also analyzed. The amounts found were $\mu\text{mol/L}$ for GSA 22.9 - 25.3, GAA 323 - 346,
6
7
8 299 GPA BDL - 0.08, CTN 4942 - 6518, GBA 0.38 - 0.43, Arg 39 - 65, G 13.8 - 16, MG
9
10 300 BDL - 3.0 and CT 2297 - 2512 with RSDs within 1.1 – 3.7%.

11
12 301 Urine samples of 12 uremic patients within the age of 49-62 years were collected
13
14 302 and analyzed (**Fig. 5 a**) and the results are summarized in **Table 2**. The amounts of
15
16 303 guanidino compounds in urine samples were observed to contain $\mu\text{mol L}^{-1}$ within the
17
18 304 range GSA 126 - 139, GAA 31.0 - 36.2, GPA below the detection limit (BDL) to 0.08, G
19
20 305 20.4 - 23.9, CTN 6425 - 6903, GBA 1.34 - 1.81, Arg 114.0 - 120.8, MG 34.8 - 39.2 and
21
22 306 CT 2697 - 2897 with RSDs within 1.5 – 3.7%. The urine sample was also spiked with
23
24 307 standard solution of guanidino compounds and the recovery was observed; 96.5, 90.4,
25
26 308 96.5, 89.4, 89.3, 88.9, 98.9 and 96.1% with RSD 1.8 – 4.3% for GSA, GAA, CTN, GBA,
27
28 309 Arg, G, MG and CTN, respectively (**Fig 5 b**).

29
30 310 The blood serum of healthy volunteers and uremic patients after deproteinization
31
32 311 with methanol was spiked with the mixture of guanidino compounds and corresponding
33
34 312 increase in the peak of compound was observed, without change in peak shape. Thus
35
36 313 deproteinized serum matrix did not interfere with the determination of guanidino
37
38 314 compounds. The results of analysis also agreed with calibration and average % recovery
39
40 315 ($n = 4$) calculated were GSA 93.3 %, GAA 112 %, GPA 100 %, CTN 98.8 %, GBA 100
41
42 316 %, Arg 97.3 %, G 100 %, MG 75 % and CT 77.6 % with RSD 2.4 %, 1.7 %, 2.9 %, 3.5
43
44 317 %, 2.6 %, 3.1 %, 2.0 %, 3.2 % and 3.0 % respectively.

45
46 318 The mean values obtained for the guanidino compounds for serum of 12 uremic
47
48 319 patients were compared with mean values of 16 healthy volunteers and t-test was applied.
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 320 A significant difference was obtained at 95% confidence level with higher concentrations
4
5 321 for GSA, GBA, Arg, MG, GAA, GPA, CTN and G for uremic patients. However no
6
7
8 322 significant difference was observed for CT. Similarly the average values for the urine of
9
10 323 12 uremic patients were compared with average values of 16 healthy volunteers and t-test
11
12 324 was again examined. A significant difference was indicated at 95% confidence level
13
14
15 325 between the averages with higher values for urine of uremic patients for GSA, GBA, Arg,
16
17 326 MG, CTN and G. A significant difference was also observed for GAA with the
18
19 327 observation of average lower concentrations of GAA in uremic patients. However no
20
21 328 significant difference was indicated for GPA and CT in urine samples of uremic patients
22
23
24 329 and healthy volunteers at 95% confidence level.

25
26
27 330 Comparing the results with reported values, it was observed that the values of GSA,
28
29 331 GAA, GPA, GBA and MG for urine of healthy volunteers agreed with reported values of
30
31 332 Gatti and Gioia¹⁸. The values for GAA, CTN, GBA and CT in the serum of healthy
32
33 333 volunteers and GSA and CT of uremic patients agreed with reported values of Marescau
34
35 334 et al³⁹. The concentration of CTN, Arg, G and MG in the serum of uremic patients and
36
37 335 GAA and CTN in the serum of healthy volunteers agreed with the reported values of
38
39 336 Kikuchi et al⁴¹.

40
41
42
43 337 The present analytical procedure was compared with reported analytical data for
44
45 338 guanidino compounds using pre column derivatization methods involving HPLC, MEKC
46
47 339 and GC. HPLC procedures combined with fluorimetric detection are sensitive, but
48
49 340 require longer analysis time and are based on gradient elution. MEKC has been reported
50
51 341 with sensitivity with shorter analysis time, but the equipment is not available with many
52
53 342 laboratories for routine analysis of the compounds. GC procedures are reported for 2 to 6
54
55
56
57
58
59
60

1
2
3 343 compounds (**Table 3**). The present method compared favorably with the reported
4
5 344 procedures in terms of sensitivity and selectivity. Use of simple reagent (MGo), complete
6
7
8 345 separation of nine guanidino compounds with shorter GC elution time of 10 .5 min are
9
10 346 the advantages of the present method.

11 12 347 **Conclusion**

13
14
15 348 An analytical procedure has been developed for GC determination of 9 guanidino
16
17 349 compounds from deproteinized serum and urine of healthy volunteers and uremic patients
18
19
20 350 using MGo and ECF as derivatizing reagents. The method indicated required sensitivity,
21
22 351 selectivity and stability for the analysis of guanidino compounds from biological samples.
23
24
25 352 The method could be used for clinical analysis of uremic patients.
