Accepted Manuscript

This is an *Accepted Manuscript*, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

*Accepted Manuscripts* are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this *Accepted Manuscript* with the edited and formatted *Advance Article* as soon as it is available.

You can find more information about *Accepted Manuscripts* in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this *Accepted Manuscript* or any consequences arising from the use of any information it contains.

23 **ABSTRACT**

24 A sensitive ultra-high performance liquid chromatography tandem mass spectrometry  
25 (UPLC-MS/MS) method was established for the simultaneous determination of  
26 fluorescent whitening agents (FWAs) and photoinitiators (PIs) in food packaging  
27 coated paper products. Samples were firstly soaked by water and then ultrasonic  
28 extracted by methanol-trichloromethane. The extracting solution were subsequently  
29 separated by a Phenomenex Luna C18 (2) chromatographic column (50 mm×2.00  
30 mm, 3 μm) using methanol-5 mmol/L ammonium acetate as the mobile phase. The  
31 target analytes were ionized by the ESI positive and negative switching mode and  
32 detected using multiple-reaction monitoring (MRM) mode. The method was validated  
33 for linearity and range, accuracy, precision and sensitivity. Under the optimized  
34 condition, the calibration curves were linear over the selected concentration ranges of  
35 10-1000 μg/L and 0.5-50 μg/L for four FWAs (FWA28, FWA85, FWA71 and  
36 FWA351) and the rest ten compounds, respectively, with calculated coefficients of  
37 determination ( $R^2$ ) of greater than 0.99. The instrument limit of quantitation (ILOQ),  
38 and the corresponding method limit of quantitation (MLOQ) of fourteen target  
39 analytes were in the range of 0.5-10 μg/L and 6-125 μg/kg, respectively. Recoveries  
40 were calculated at three levels of concentration spiked in negative samples and the  
41 values were found between 79.2% and 115% with relative standard deviation (RSD)  
42 values of 3.2%-12.3% for intra-day precision ( $n = 6$ ) and 4.5%-11.5% for inter-day  
43 precision ( $n = 5$ ) 2.5-7.2%. The method was successfully applied to analyse  
44 twenty-five food packaging coated paper products samples and FWA184 and 4-MBP

1  
2  
3  
4 45 were detected in only two samples with the concentrations of 151  $\mu\text{g}/\text{kg}$  and 32  $\mu\text{g}/\text{kg}$ ,

5  
6 46 respectively.

## 52 Introduction

53 Fluorescent whitening agents (FWAs), colorless or weakly colored organic  
54 compounds, which can absorb light in the UV range (290-400 nm) and emit visible  
55 blue light (400-480 nm), thus enhancing the optical impression of “brightness” and  
56 “whiteness”, are widely used in household detergents to eliminate the yellowish cast  
57 of white fabrics and increase the whiteness and brightness of products. In recent years,  
58 with the rapid development of industries, FWAs are also extensively applied in  
59 textiles, coatings, plastics and even paper manufacturing.<sup>1-4</sup> Although thousands of  
60 FWAs are available, only approximately 400 of them are used widely and most of  
61 FWAs used in paper and board manufacturing are based upon stilbene derivatives.<sup>5</sup>  
62 Toxic effects of FWAs have not yet been observed, indicating that the contact with  
63 FWAs or even FWAs that migrate into food from food contact products does not  
64 represent a risk to human health. However, the chemical stability of FWAs make them  
65 hard to degrade, in addition, the over-use of them can also lead to environmental  
66 pollution, which has the potential to transfer to human beings through the food chain  
67 and accumulate in the bodies and threaten our health.<sup>3, 5</sup> In China<sup>6</sup> and the western  
68 countries,<sup>7-8</sup> FWAs are authorized to be used in materials in contact with food as food  
69 additives, for example, FWA184, FWA393 and FWA236 can be used in the EU and  
70 China according to the regulations of 2002/72/EC and GB 9685-2008.<sup>9</sup> But not all of  
71 them are authorized for use by the US Food and Drug Administration and their  
72 inclusion in paper and board (P&B) intended for food packaging in the European  
73 Union (EU) is under consideration due to their potential migration to the packaged

1  
2  
3  
4 74 products.<sup>5</sup> Moreover, the usage limitation, even the specific migration limits (SPL) are  
5  
6 75 clearly described in relevant food regulations. For example, according to GB  
7  
8 76 9685-2008,<sup>9</sup> the SPL of FWA184 is 0.6 mg/kg and the maximum usages in  
9  
10 77 polystyrene (PS) and polyvinyl chloride (PVC) materials are 0.02% and 0.015%,  
11  
12 78 respectively. In these circumstances, appropriate methods which a simultaneously  
13  
14 79 determine the concentrations of FWAs in food contact products are required.  
15  
16  
17  
18

19 80 Photoinitiators (PIs), which are low molecular weight compounds and can be used  
20  
21 81 to utilize activity substance produced by photosensitive groups to initiate  
22  
23 82 polymerization during the process of optical absorption, have been widely used in  
24  
25 83 packaging materials as a main component of UV inks.<sup>10</sup> The withdrawal from the  
26  
27 84 market of more than 30 million liters of milk by Italian authorities hit the headlines  
28  
29 85 for food contamination in 2005. It was mainly because that a kind of photoinitiator  
30  
31 86 (2-isopropylthioxanthone (2-ITX)) migrated into infant milk was detected by Italian  
32  
33 87 Food Control Authority with the concentrations of 120 µg/L to 300 µg/L. Recent  
34  
35 88 studies have found that after the curing completion of the printing ink, the remaining  
36  
37 89 PIs can migrate through chemical or physical contact under certain conditions,  
38  
39 90 resulting in contamination of the food inside the packaging, and so as have the  
40  
41 91 potential harm to human body health.<sup>11-13</sup> On account of this circumstance, the foreign  
42  
43 92 countries successively promulgated the regulations and licensing list to restrict the use  
44  
45 93 of PIs, for example, the SPLs of benzophenone (BP), 4-methyl benzophenone  
46  
47 94 (4-MBP) and 4, 4'-Bis(dimethylamino)-benzophenone (MK) were regulated by EU as  
48  
49 95 0.6, 0.6 and 0.01 mg/kg, respectively. Therefore, appropriate methods to determine  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 96 PIs in food contact products are also extremely required.  
5

6 97 It has been reported that FWAs and PIs can be determined by ultraviolet light  
7  
8 98 observation method, gas chromatography-mass spectrometry, high-performance liquid  
9  
10 99 chromatography, and ion-pair high-performance liquid chromatography/tandem mass  
11  
12 100 spectrometry.<sup>1-5</sup> Chen, et al. adopted solid-phase extraction and ion pair liquid  
13  
14 101 chromatography-tandem mass spectrometry to determine FWAs in environmental  
15  
16 102 waters and favorable limits of quantitation (LOQs, 4 to 18 ng/L) were obtained, but  
17  
18 103 mean recoveries were between 68 and 97%. In another study, a novel, single step  
19  
20 104 method for the determination of seven ink photoinitiators in carton packed milk  
21  
22 105 samples was developed, The LOQs of the optimized method were between 0.2 and 1  
23  
24 106  $\mu\text{g/L}$  and a good linearity in the range between 1 and 250  $\mu\text{g/L}$  was obtained.<sup>14</sup>  
25  
26 107 However, these methods mentioned above are available only in the matrix of water,  
27  
28 108 laundry detergents, and infant clothes for FWAs determination and beverages, milk,  
29  
30 109 and other packaged food for PIs determination, to our best knowledge, few reports  
31  
32 110 have been focused on the determination of FWAs and PIs in food packaging coated  
33  
34 111 paper products. In the present work, fourteen FWAs and PIs in food packaging coated  
35  
36 112 paper products were simultaneously determined by ultra-high performance liquid  
37  
38 113 chromatography tandem mass spectrometry (UPLC-MS/MS) using the ESI positive  
39  
40 114 and negative switching mode. More satisfactory validation parameters were obtained,  
41  
42 115 including linearity, accuracy, precision, and ILOQs and MLOQs, comparing with the  
43  
44 116 method mentioned in the above references. The developed method can provide  
45  
46 117 reference for the detection and specific migration study of related compounds in food

5  
6 141 **Instrumentation**

7  
8 142 The ACQUITY™ ultra high performance liquid chromatography and Waters Xevo™  
9  
10 143 TQ tandem triple quadrupole mass spectrometer (UPLC-MS/MS, Waters Co., USA)  
11  
12 144 were used for sample analysis. The samples were vortex mixed with a MS3 basic  
13  
14 145 vortex mixer (IKA GmbH, Germany), ultrasonicated by the KQ-250DV  
15  
16 146 numerically-controlled ultrasonic cleaner (Kunshan Ultrasonic Instrument Co., Ltd,  
17  
18 147 China) and centrifuged by a LD5-2A centrifuge (Beijing Jingli Centrifuge Co., Ltd,  
19  
20 148 China). The Milli-Q A10 (Millipore Co., USA) was used to offer Milli-Q water (18.2  
21  
22 149 MΩ·cm).

23  
24  
25  
26  
27  
28 150 **Standard solutions**

29  
30 151 Appropriate amounts of FWA28, FWA85, FWA71, FWA351, FWA52, FWA184, BP,  
31  
32 152 4-MBP and MK were dissolved in methanol respectively to obtain the individual  
33  
34 153 standard stocking solutions (100 mg/L). Individual standard stocking solutions of the  
35  
36 154 rest five analytes were prepared at the concentration of 100 mg/L in trichloromethane.  
37  
38 155 The mixed standard stocking solution with the concentrations of FWA28, FWA85,  
39  
40 156 FWA71 and FWA351 of 10 mg/L and the concentrations of the rest analytes of 5  
41  
42 157 mg/L was prepared by diluting the each individual standard stocking solution with  
43  
44 158 methanol, which was then stored in refrigerator at -20°C.

45  
46  
47  
48 159 Before use, the mixed standard working solutions were obtained by further  
49  
50 160 stepwise diluted the mixed standard stocking solution to the required concentrations  
51  
52 161 (Concentrations of FWA28, FWA85, FWA71 and FWA351 were 10, 25, 50, 250 and  
53  
54 162 1000 µg/L, and the rest ten analytes were 0.5, 1.0, 5.0, 20 and 50 µg/L, respectively)  
55  
56 163 with 60% methanol-water solution (v/v). All of the standard working solutions were  
57  
58  
59  
60

1  
2  
3 164 preserved in refrigerator at 4°C.  
4

5 165 Moreover, the matrix calibration working solutions of required concentrations were  
6  
7 166 prepared using the negative sample extracting solution which was obtained according  
8  
9 167 to the next section.  
10

### 11 12 168 **Sample and sample preparation** 13

14  
15 169 Two kinds of food packaging coated paper products were provided by National centre  
16  
17 170 for quality supervision and testing of packaging products (Guangzhou), one of which  
18  
19 171 (A) was confirmed to have FWA351 and FWA184, the other (B) was confirmed to  
20  
21 172 contain 4-MBP. Additionally, twenty-five coated paper products samples, including  
22  
23 173 paper cup, paper bowl, paper bag, and so on, were purchased from local market.  
24  
25

26  
27 174 All paper products were cut into 5 mm × 5 mm in size and mixed evenly. Then, 0.5  
28  
29 175 g of as-prepared sample, 3 mL of water were orderly added into a 25 mL of stoppered  
30  
31 176 colorimetric tube and the mixture was ultrasonicated for 20 min. 20 mL  
32  
33 177 methanol-trichloromethane (7 : 3, v/v) was added into the colorimetric tube and  
34  
35 178 subsequently ultrasonicated for 30 min. After that, the extracting solution was diluted  
36  
37 179 to 25 ml with methanol, then 10 mL of which was withdrawn into glass centrifuge  
38  
39 180 tube and centrifuged at 3000 rpm for 5 min. Subsequently, 5 mL of supernatant was  
40  
41 181 withdrawn into nitrogen blowpipe and concentrated to dry in water bath at 40°C under  
42  
43 182 nitrogen blowing. Finally, the dried analyte was dissolved with 1.0 mL 60%  
44  
45 183 methanol-water solution (v/v) and the solution was transferred into a sample tube for  
46  
47 184 UPLC-MS/MS analysis.  
48  
49

### 50 51 185 **UPLC-MS/MS conditions** 52

53  
54  
55 186 Chromatographic separation was performed on the Acquity™ UPLC system with a  
56  
57  
58  
59  
60

1  
2  
3  
4 187 Phenomenex Luna C18 (2) chromatographic column (50 mm×2.00 mm, 3 μm).  
5  
6 188 Separation of target analytes was achieved by a gradient elution program with the  
7  
8  
9 189 mobile phase of a mixture of 5 mmol/L ammonium acetate (A) and methanol (B). The  
10  
11 190 gradient elution program was optimized as follows: started from 60% A and a linear  
12  
13 191 gradient to 40% A in 2 min, then decreased to 5% A in 3 min and maintained for 1.5  
14  
15 192 min, subsequently, 60% A was obtained from 5% A in 1.5 min and maintained for 2  
16  
17 193 min, the total run time was 9.0 min. The flow-rate was set as 0.4 mL/min and the  
18  
19 194 column temperature was kept in constant of 40°C. An injection volume of 5 μL was  
20  
21 195 performed using an auto-sampler.  
22  
23  
24  
25

26 196 MS/MS detection was performed on a triple quadrupole mass spectrometer detector  
27  
28 197 equipped with a jet stream electro spray ionization (ESI) source. ESI positive and  
29  
30 198 negative subsection acquisition mode (0-3.2 min was in ESI<sup>-</sup> mode and 3-9 min was in  
31  
32 199 ESI<sup>+</sup> mode) was used for quantification with the capillary voltage of 1.5 kV. The  
33  
34 200 switching time from negative ESI mode to positive ESI mode was 20 ms. The ion  
35  
36 201 source temperature and desolvation temperature were optimized at 150 and 400°C.  
37  
38 202 The flow rates of the desolvation gas (N<sub>2</sub>), cone gas (N<sub>2</sub>) and collision gas (Ar) were  
39  
40 203 set at 800 L/h, 50 L/h and 0.20 mL/min, respectively. The MS detector was operated  
41  
42 204 in multiple reaction monitoring (MRM) mode for all analytes and the cone voltage,  
43  
44 205 collision energy and the other MS parameters of fourteen target analytes are shown in  
45  
46  
47  
48  
49  
50

51 **Table 1.**

## 54 **Results and discussion**

### 56 **Optimization of extraction solvent**

1  
2  
3  
4 209 According to the principle that the similar substance is more likely to be dissolved by  
5  
6 210 each other, the extraction solvent should sufficiently extract target compounds and  
7  
8  
9 211 decrease the extraction of the other interfering components as far as possible. Among  
10  
11 212 the fourteen target compounds, the solubility of FWA367, FWA135, FWA185,  
12  
13 213 FWA368 and FWA393 in trichloromethane is bigger than that in methanol and  
14  
15  
16 214 acetonitrile, while FWA28, FWA85, FWA71, FWA351, FWA52, FWA184, BP,  
17  
18  
19 215 4-MBP and MK are soluble in methanol. Therefore, methanol-trichloromethane  
20  
21 216 extraction solvent was selected and the effects of different ratios of methanol versus  
22  
23 217 trichloromethane (9 : 1, 8 : 2, 7 : 3, 6 : 4, 5 : 5, 4 : 6) on the recoveries of target  
24  
25  
26 218 analytes were investigated. In the present work, 20  $\mu$ L of mixed standard stocking  
27  
28  
29 219 solution was added into a negative sample and the sample was subsequently stored in  
30  
31 220 dark for 4 h to absorb the standard solution sufficiently. Then the sample was  
32  
33  
34 221 extracted using the methanol-trichloromethane extracting solvent of different ratios.  
35  
36 222 Relying on obtained results (**Table 2**), it can be assumed that as trichloromethane was  
37  
38  
39 223 increased, there were increases in the recoveries of FWA367, FWA135, FWA185,  
40  
41 224 FWA368 and FWA393. It was worth mentioning that the recovery of FWA393 was  
42  
43  
44 225 observably increased with the increase of trichloromethane. However, the recoveries  
45  
46 226 of these five analytes reached stationary values when the ratio of trichloromethane  
47  
48  
49 227 was 40%. On the contrary, the recoveries of FWA28, FWA85, FWA71 and FWA351  
50  
51 228 decreased along with the increase of trichloromethane. As for FWA52, FWA184, BP,  
52  
53  
54 229 4-MBP and MK, there were no obvious changes in recoveries with increasing  
55  
56 230 trichloromethane. It was noticeable that the recoveries of all analytes were relatively  
57  
58  
59  
60

1  
2  
3  
4 231 favorable when the ratio of methanol versus trichloromethane was 7 : 3 (v/v). In  
5  
6 232 addition, in consideration of the circumstance that FWA28, FWA85, FWA71 and  
7  
8  
9 233 FWA351 are always added in the form of sodium salt in the industrial production, and  
10  
11 234 with regard to dried samples, soaking with water can accelerate the dispersion of  
12  
13 235 sample matrix and enhance the extracting recoveries. Thus, the effects of different  
14  
15 236 extracting ways, methanol-trichloromethane (7 : 3, v/v) extraction with and without  
16  
17 237 water soaking, on the recoveries of samples A and B were also studied. One obvious  
18  
19 238 feature presented in **Fig. 2** was that favorable contents of target analytes were  
20  
21 239 obtained using methanol-trichloromethane (7 : 3, v/v) extraction with water soaking  
22  
23 240 pretreatment. For example, the content of FWA351 increased by 12.2% with water  
24  
25 241 soaking pretreatment. Hence, all sample were firstly soaked with water and then  
26  
27 242 extracted by methanol-trichloromethane (7 : 3, v/v).

#### 23 243 **Optimization of chromatography and mass spectrometry conditions**

24 244 FWA28, FWA85, FWA71 and FWA351 are stilbene FWAs whose structures contain  
25  
26 245 sulfonic acid group ( $-\text{SO}_3^-$ ), which have the highest responses of precursor ions  
27  
28 246 ( $[\text{M}-2\text{H}]^{2-}$ ) under the ESI negative mode. The remaining seven FWAs, which contain  
29  
30 247 tertiary nitrogen atoms, can generate  $[\text{M}+\text{H}]^+$  under the ESI positive mode, likewise,  
31  
32 248 BP, 4-MBP and MK can also generate  $[\text{M}+\text{H}]^+$  under the ESI positive mode.  
33  
34 249 Therefore, the present work adopted the ESI positive and negative switching mode to  
35  
36 250 analyze fourteen target analytes. The collision energy, cone voltage and the other  
37  
38 251 parameters were optimized to obtain the best response of the analytes. The optimized  
39  
40 252 parameters were presented in **Table 1**.

1  
2  
3  
4 253 The effects of three kinds of mobile phase system, including acetonitrile-water  
5  
6 254 system, acetonitrile-10 mmol/L ammonium acetate system and methanol-10 mmol/L  
7  
8  
9 255 ammonium acetate system, on the chromatographic separation were investigated. The  
10  
11 256 results found that four kinds of toluylene FWAs had unfavorable peak shape in the  
12  
13  
14 257 acetonitrile-water system. By adding ammonium acetate solution, which provides a  
15  
16 258 certain number of ionic strength, can effectively improve the peak shape and achieve  
17  
18  
19 259 well separation for these FWAs. When methanol was used as the organic phase, it  
20  
21 260 could provide proton for the compounds ionized under ESI+ mode, that is why the  
22  
23  
24 261 response is apparently higher than that with acetonitrile as the organic phase.  
25  
26 262 Moreover, the concentration of ammonium acetate could suppress the ionization of  
27  
28  
29 263 analytes, thereby influence the response of target analytes. So, in the present work,  
30  
31 264 effects of ammonium acetate with the concentrations of 2 mmol/L, 5 mmol/L and 10  
32  
33  
34 265 mmol/L on the chromatographic behavior of fourteen target analytes were also studied.  
35  
36 266 The results indicated that as the concentration of ammonium acetate was increased,  
37  
38  
39 267 there was a decrease in peak area of fourteen target analytes and longer retention time.  
40  
41 268 The peak shape of FWA28 was bifurcate under the concentration of 2 mmol/L, while  
42  
43  
44 269 in the concentrations of 5 mmol/L, the peak shape of all compounds were favorable  
45  
46 270 and the stability of retention time and peak area were good. Therefore, methanol-5  
47  
48  
49 271 mmol/L ammonium acetate system was chosen as the mobile phase for the following  
50  
51 272 experiment. The selected ion chromatograms of fourteen target analytes under the  
52  
53  
54 273 optimized instrumental conditions were shown in **Fig. 4**.

56 274 **Method validation**

275 *Method specificity*

276 The developed method was applied to determine target analytes in twenty negative  
277 samples. In the meantime, sample solutions added with the fourteen target analytes  
278 were also determined by this method. The results found that impurity compositions in  
279 the samples had no interference effects on the determination of all the fourteen target  
280 analytes because of the preferable chromatographic separation of fourteen compounds  
281 and high selectivity of the triple quadrupole mass spectrometry, indicating that the  
282 specificity of the developed method was favorable.

283 *Linearity range, ILOQs, MLOQs and matrix effects*

284 The method developed to determine fourteen FWAs and PIs in food packaging coated  
285 paper products samples was validated by studying the linear ranges, instrument limit  
286 of quantitation (ILOQ), method limit of quantitation (MLOQ) and the repeatability  
287 (expressed as relative standard deviation (RSD)) for all the compounds, under  
288 optimized instrumental conditions. The results obtained are summarized in **Table 3**.  
289 The standard curves were obtained by plotting the ratios of each target analyte  
290 quantitative ion peak area (on the ordinate (y)) versus the corresponding mass  
291 concentrations (on the abscissa (x,  $\mu\text{g/L}$ )) using five concentration levels in duplicate.  
292 In the mean time, a series of matrix calibration solutions were prepared by using  
293 negative matrix extracting solutions, and the corresponding matrix calibration curves  
294 were obtained likewise. The matrix effects (ME) were investigated according to the  
295 slopes' ratio of calibration curve of the matrix versus standard working curve of pure  
296 solvent (ME > 1 and ME < 1 represent matrix enhancement and matrix suppression,

1  
2  
3  
4 297 respectively).

5  
6 298 The instrument limit of detection (ILOD), ILOQ, which refers the triple  
7  
8  
9 299 signal-to-noise ratio ( $S/N = 3$ ) and tenfold signal-to-noise ratio ( $S/N = 10$ ), were  
10  
11 300 measured by gradually diluting the standard solution with pure solvent. The results  
12  
13 301 found that the ILOQs of fourteen target analytes were in the range of 0.5-10  $\mu\text{g/L}$ . By  
14  
15 302 taking the pretreatment processes and the recoveries of various samples into  
16  
17 303 consideration, the corresponding MLOQ were between 6  $\mu\text{g/kg}$  and 125  $\mu\text{g/kg}$  (**Table**  
18  
19 304 **3**), indicating the high sensitivity of the developed method. Additionally, in the  
20  
21 305 concentration ranges of 10-1000  $\mu\text{g/L}$  and 0.5-50  $\mu\text{g/L}$  for four FWAs (FWA28,  
22  
23 306 FWA85, FWA71 and FWA351) and the remaining ten compounds, respectively, all of  
24  
25 307 the correlation coefficients were more than 0.99, indicating the good linear  
26  
27 308 relationship between the quantitative ion peak areas and analyte concentrations. For  
28  
29 309 these compounds, the slope ratios between matrix calibration curves and pure  
30  
31 310 standard solution curves were in range of 0.82-1.33, manifesting that the matrix  
32  
33 311 effects were very small and thus could be ignored.

34  
35  
36  
37  
38  
39  
40  
41 312 *Accuracy, precision and stability*

42  
43 313 Negative samples at three spiked levels of analytes with  $1 \times \text{MLOQ}$ ,  $5 \times \text{MLOQ}$ ,  $50 \times$   
44  
45 314  $\text{MLOQ}$  of mixed standard substances were used to test the recoveries and inter-day  
46  
47 315 precision of analytes according to the proposed method, with six identical samples ( $n$   
48  
49 316 = 6) tested at each concentration, in addition, the intro-day precision was also  
50  
51 317 investigated by analyzing five spiked replicates ( $n = 5$ ) for  $5 \times \text{MLOQ}$  level. The  
52  
53 318 results indicated that the recoveries of the fourteen target analytes were satisfactory  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 319 with values in the range of 79.2%-115% (Table 4). Moreover, relative standard  
5  
6 320 deviations (RSDs) of 3.2%-12.3% for intra-day precision ( $n = 6$ ) and 4.5%-11.5% for  
7  
8 321 inter-day precision ( $n = 5$ ) were observed, meaning that the accuracy, precision and  
9  
10 322 stability can meet the requirements for such an analysis.

### 11 12 13 323 **Analysis of practical samples**

14  
15  
16 324 The method established in this work was adopted to determine a total of twenty-five  
17  
18 325 food packaging coated paper products samples collected from local markets. Among  
19  
20 326 these samples, two samples were found to contain FWA184 and 4-MBP, and the  
21  
22 327 contents were determined to be 151  $\mu\text{g}/\text{kg}$  and 32  $\mu\text{g}/\text{kg}$ , respectively. No FWAs and  
23  
24 328 PIs were detected in the remaining samples.

### 25 26 27 329 **Conclusions**

28  
29  
30 330 A simple and sensitive analytical method, using UPLC-MS/MS technique, was  
31  
32 331 developed for the simultaneous determination of eleven FWAs and three PIs in food  
33  
34 332 packaging coated paper products samples. The ESI positive and negative switching  
35  
36 333 mode and MRM way were adopted to detect the target analytes. Satisfactory  
37  
38 334 validation parameters were obtained, including linearity, accuracy, precision, and  
39  
40 335 ILOQs and MLOQs. In addition, the method is simple in pretreatment and low in  
41  
42 336 reagent consumption. The results obtained confirm the suitability of the method  
43  
44 337 proposed for FWAs and PIs determination in food packaging coated paper products  
45  
46 338 samples.
