Metal-organic frameworks (MOFs), composed of organic ligands and metal nodes, are well known for their high and permanent porosity, crystalline nature and versatile potential applications, which promoted them to be one of the most rapidly developing research focuses in chemical and material science. During the various applications of MOFs, the photoluminescence properties of MOFs have received growing attention, especially for the nitroaromatics (NACs) sensing, due to the consideration of homeland security, environmental cleaning and military issues. In this highlight, we summarize the recent research progress in NACs sensing based on LMOFs cataloged by sensing technique in the last three years, and then we describe the sensing applications on nano-MOF type materials and MOF film, together with MOF film applications.

Introduction

With the increasing use of explosive materials in terrorism all over the world, how to reliably and efficiently detect tracing explosive materials has become a highlight research focus in recent years because of homeland security, environmental cleaning and military issues.¹ Additionally, the reliable identification of chemical explosives in post-blast residues is of great important for criminal investigations.^{1d,2} As one of major classes of secondary explosives, nitroaromatics (NACs), which are composed of a benzene ring functionalized with several nitro-groups, have become serious pollution sources of groundwater, soils, and other security applications due to their explosivity and high toxicity, such as 2,4,6-trinitrotoluene (TNT), 2,4-dinitrotoluene (2,4-DNT) and picric acid (PA) (Fig. 1). The detection of this class of explosives is not easy because of their moderate vapor pressures and limited chemical reactivity.^{1e} Thanks to the development of instrumental techniques together with sniffer dogs,³ new ways to detect

explosives are being developed to improve security, including gas chromatography coupled with mass spectrometry (GC-MS), surface-enhanced Raman spectroscopy, neutron activation analysis, X-ray imaging, ion mobility spectroscopy (IMS), energy dispersive X-ray diffraction (EDXRD), plasma desorption mass spectrometry (PDMS) and so on.^{1k, 4} These techniques are highly selective and sensitive, but some are of high cost and time-consuming, simultaneously others are not easy to operate and be assembled in a small and low-power package. Therefore, another new technology need to be developed so that we may cheaply and rapidly complete detection. The electron-deficient particular property of NACs is favorable for forming π -stacking complexes with electron-rich fluorophores, which can be applied to their detection with chromo-fluorogenic probes. Chemical sensors provide new approaches to the rapid detection of ultra-trace NACs from explosives, and can be easily incorporated into inexpensive and portable microelectronic devices. In this respect, the

fluorescence-based sensor schemes probably show a very promising future.

Fig. 1 Chemical structures of common NACs molecules.^{1f}

All sorts of conjugated polymers (CPs) have been used to sensing NACs with high sensitivity and selectivity, due to their π -electron-rich characteristic and high binding strength to NACs.^{1i, 5} The delocalized π^* excited state of the CPs can significantly enhance their donor ability and enable them to interact strongly with nitrated aromatic compounds through π - π interactions. However, the applications of conjugated polymeric sensors are limited for their stability, multi-step synthesis and poor molecular organization. In addition, it has also been noted that porosity may play an important role in the sensing performance, as illustrated in porous amplifying fluorescent polymer (AFP) films, metalloporphyrin-doped mesostructured films and fluorescent nanofibril films.

Metal-organic frameworks (MOFs) materials, constructed from multi-topic organic ligands and metal cations or clusters, have been extensively studied during the past decade for their intriguing structural diversity and potential applications including selective gas adsorption and separation,⁶ catalysis,⁷ luminescent sensing^{3a, 8} and drug delivery.⁹ MOFs have become

one of the most rapidly developing research focuses in chemical and materials sciences. The most attractive features of MOFs are their high and permanent porosity, long range order, high surface area, as well as uniform pore sizes in the nanoscale range. Additionally, the chemical versatility and structural tailorability provide a significant level of tenability to the physical and chemical properties of MOFs. The judicious combination of metal ions and predesigned organic ligands under suitable reaction conditions affords various kinds of MOF structures with desired functionalities.¹⁰ The luminescence of MOFs originates from the rigid ligands with aromatic moieties or extended π systems and/or metal components especially for lanthanides and inorganic clusters, excimer and exciplex, or guest molecules. Compared with free organic ligand, the advantages of using MOFs as sensory materials are as follows. At first, MOFs in solid may reduce the non-radiative decay rate and leads to increased fluorescence intensity, lifetimes, and quantum efficiencies. In addition, the multifunction of MOFs can easily be modulated by post-synthetic modification and it is supposed that unsaturated metal centers or open metal sites plays important part in absorption/separation including gas and guest molecules. Most notably, the sustainable pores within LMOFs provide a natural habitat for guest molecules. The combination of porosity and luminescence in MOFs makes them potential candidates for the sensing of NACs. After reported by Li in 2009, the fluorescence based sensing materials have recently been considered as one of the most excellent and promising techniques in the detection of NACs.^{1c}

The possible mechanisms of luminescent MOFs for sensing NACs are based on fluorescent quenching, including an electron transfer or energy transfer process, or a combination of the two between fluorophore and NACs, and the similar physical process have been investigated in conjugated polymers.^{2, 3c, 11} The fluorescent quenching mechanism based on electron transfer can also be divided into static quenching and dynamic quenching. The static quenching takes place in the

ground-state via non-fluorescent electron-transfer complex formation, which decreases the intensity of steady-state emission, without changing the life-time of LMOFs. On the contrary, the dynamic quenching occurs in the excited state with electron-transfer process, which decreases the steady-state emission intensity and life-time of LMOFs simultaneously. As mentioned above, NACs are electron-deficient analytes and LMOFs can be regarded as electron-rich fluorophore molecules, whose valence and conduction bands can be treated in the similar way of molecular orbitals (MOs). The vapor pressure and reduction potential of common explosives and selected analytes are listed in Table 1. The electronic properties of LMOFs and NACs are equally important for efficient sensing. In general, the conduction of a LMOFs lies at higher energies than the LUMOs of NACs, and thus maintains a better driving force for the electron transfer to electron-deficient NACs, leading to the fluorescent quenching. Stern-Volmer analysis can be used to evaluate the efficiency of particular LMOFs for NACs in liquid medium quantitatively using Equation(1).

$$I_0/I_f = 1 + k_{sv}[Q], \quad \text{Equation(1)}$$

Where I_0 and I_f are the fluorescent intensities of LMOFs before and after the addition of NACs. k_{sv} is Stern-Volmer constant and $[Q]$ stands for the concentration of NACs. The higher k_{sv} means high sensing efficiency. But the electron transfer is not the sole mechanism, the fluorescent quenching mechanism sometime originates from the case of energy transfer or the combination of electron and energy transfer. If the emission band of LMOFs and the absorption band of the NACs are efficiently overlapped, the energy transfer process may occur and will severely improve the fluorescence quenching

efficiency and sensibility. The probability of resonance energy transfer depends on the extent of spectral overlap between the emission of LMOFs and the absorption of NACs. The extent of energy transfer was determined by calculating the integral of overlap (J_λ) values using Equation(2).¹² Where, $F_D(\lambda)$ is the corrected fluorescence intensity of donor in the range of λ to $\lambda+\Delta\lambda$ with the total intensity normalized to unity, and ϵ_A is extinction coefficient of the acceptor at λ in $M^{-1} cm^{-1}$.

$$J(\lambda) = \int_0^\infty F_D(\lambda)\epsilon_A(\lambda)\lambda^4 d\lambda \quad \text{Equation(2)}$$

The advantages and challenges of LMOFs based on chemical sensing and explosive detection have been well summarized by recent review articles.^{1f, 8b, 8c, 11, 13} Our research interest focus on NACs sensing based on LMOFs. In this highlight, we summarize the recent research progress in NACs sensing based on LMOFs cataloged by sensing technique in the last three years, and then we describe the sensing applications on nano-MOF type materials and MOF film, together with MOF film applications.

Table 1 The vapor pressure of common NACs

Analyte	Vapor pressure (in mmHg, ^a at 25 °C)
Nitrobenzene (NB)	0.2416
1,3-Dinitrobenzene (<i>m</i> -DNB)	8.82×10^{-4}
1,4-Dinitrobenzene (<i>p</i> -DNB)	2.406×10^{-5}
2-Nitrotoluene (NT)	0.1602
2,4-Dinitrotoluene (2,4-DNT)	1.44×10^{-6}
2,6-Dinitrotoluene (2,6-DNT)	5.61×10^{-4}
2,4,6-Trinitrotoluene (TNT)	8.02×10^{-6}
Picric acid (PA)	5.8×10^{-9}

^a1 mmHg = 1.2468 × 103 ppm.

Table 2 List of selected LMOFs in recent three years.

2 MOFs for NACs sensor

As a new frontier for material research, Metal-organic frameworks (MOFs) have gathered numerous attentions in the last decades, due to their multi-functional applications. A brand new field of MOF research which associated with NACs detection was represented after firstly reported by Li etc. Among the reported studies, MOFs or hybrid MOFs were

applied to detecting NACs with high selectivity and sensitivity in vapor phase, liquid phase and/or aqueous phase. The results show that LMOFs are kinds of promising materials to trace the nitroaromatic explosives.

2.1 Detection in vapor phase

Gas sensors have a wide range of application in the fields of aerodynamics, environmental analysis, analytical chemistry, and biochemistry. As the luminescent properties of MOFs can

also be perturbed by gases and vapors, some luminescent MOFs for sensing of gases and vapors have been also explored.^{3a, 11} The very first MOF used as sensor in vapor phase to detect NACs explosives was reported by Li's group.^{1c} They designed and synthesized a fluorescent MOF, $[\text{Zn}_2(\text{bpdc})_2(\text{bpee})] \cdot 2\text{DMF}$ (bpdc = 4,4'-biphenyldicarboxylate; bpee = 1,2-bipyridylethene; DMF = dimethyl formamide). The MOF consisted of 1D open channels, in which DMF molecules were filled in, and the solvent molecules could be removed by heating under vacuum to obtain the guest-free MOF. The guest-free MOF showed strong fluorescence in solid state. To explore the applicability for detecting the NACs, the guest-free MOF was made as thin layer. The sample showed rapid and reversible response to DNT vapor, the quenching percentage reached 85% within 10 seconds. Thus, it is important that the samples can detect DNT circularly by heating the samples at 150 °C for one minute. Moreover, Li's group also reported a Zn based LMOF, LMOF-121 or $[\text{Zn}_2(\text{oba})_2(\text{bpy})] \cdot \text{DMA}$, H_2oba = 4,4'-oxybis-(benzoic acid), bpy = 4, 4'-bipyridine, DMA = *N*, *N*'-dimethylacetamide).^{1g} As shown in Fig. 2, LMOF-121 possessed a 3D network built from a $\text{Zn}_2(\text{oba})_4$ paddle-wheel SBU. The structure contained one-dimensional open 1D channels running along both the 100 and 010 directions, where the DMA molecules resided. To obtain the empty pore for capturing the guest molecule, LMOF-121 was heating at 160 °C to remove DMA molecules, as $\text{LMOF-121}'$. The fluorescent spectra of $\text{LMOF-121}'$ was carried in thin layer, which showed strong emission at 420 nm (λ_{ex} = 280 nm). The layer was exposed to different NACs with electron withdrawing groups. The results indicated that all the NACs used in the article acted as fluorescent quenchers. The quenching efficiency (%) of NB was 84% which was the highest one (Fig.3). In the vapor phase, the quenching efficiency is not only affected by the strong electron-withdrawing $-\text{NO}_2$ group, but also associated with the vapor pressure. Recently, the same group reported a series of fluorescence active MOFs built on paddle-wheel secondary building units (SBUs), including $[\text{Zn}(\text{ndc})(\text{bpe})_{0.5}]$ (**1**),

$[\text{Zn}(\text{ndc})(\text{bpee})_{0.5}]$ (**2**), $[\text{Zn}(\text{ndc})(\text{ted})_{0.5}]$ (**3**) and $\text{Zn}(\text{ndc})(\text{bpy})_{0.5}$ (**4**) [ndc = 2,6-naphthalenedicarboxylic acid; bpe = 1,2-bis(4-pyridyl)-ethane; bpee = 1,2-bis(4-pyridyl)-ethylene; ted = triethylenediamine, bpy = 4,4' -bipyridine]. All compounds performed luminescent quenching when they are exposed to the NACs vapor. Among them, complex **3** possesses the best quenching ability, with the quenching ratio about 84% and 51% for NB and NT vapor respectively.⁶⁹ The similar results can be observed in Wang,⁶⁶ and Shen's⁶⁸ work.

LMOFs can also be synthesized via microwave assisted method, because it sharply reduces the over-all processing time, increases the product yield and improves the quality of the product. Compared to their solvothermally synthesised counterparts, microwave-assisted LMOFs with homogenous microcrystals give increased sensing sensitivities. Parkin and coworkers reported two fluorescent metal-organic frameworks $[\text{Zn}(\text{dcbpy})(\text{DMF})] \cdot \text{DMF}$ (**1**) and $[\text{Dy}(\text{dcbpy})(\text{DMF})_2(\text{NO}_3)]$ (**2**) (dcbpy = 2,2'-bipyridine-4,4'-dicarboxylate), together with microwave synthesized form, as **1M**. Microporous **1** and nonporous **2** give organic linker-based fluorescence emission. And then MOFs **1**, **1M** and **2** were tested for their ability to act as sensory materials to TNT derivatives: 2,4-dinitrotoluene (2,4-DNT), para-nitrotoluene (*p*-NT) and nitrobenzene (NB), as well as plastic explosive taggant 2,3-dimethyl-2,3-dinitrobutane (DMNB) in vapor phase. They demonstrated very different detection capabilities towards the explosive taggant. Compared with non-homogenous microcrystals of **1'**, **1M** shows greater sensitivities of quenching responses when exposed to DMNB and NB. They believe that the differences are attributed to the variation in the overall framework architecture between the two MOFs. This paper reiterates the key importance of MOF porosity in sensing applications, and highlights the value of uniform microcrystals to sensitivity.⁷⁰

2.2 Detection in liquid phase

In recent years, most LMOFs for NACs sensors are detected in organic liquid phase, including EtOH, MeOH, DMF, DMA, DMSO and MeCN, especially for unstable MOFs. Our group has reported an example of MOFs as efficient sensor for NACs detection.³⁴ $[\text{Eu}_2(\text{L}^7)(\text{H}_2\text{O})_3]\cdot 2\text{H}_2\text{O}$ ($\text{H}_3\text{L}^7 = 1,3,5\text{-tris(4-carboxyphenyl-1-ylmethyl)-2,4,6-trimethylbenzene}$) was crystallized in orthorhombic, space group of $Pnma$. As showed in Fig. 4(a)-(d), the binuclear Eu clusters are connected to each

other by two carboxylate groups to form 1D infinite rod-shaped SBU along the c axis. The 1D chain is further linked by ligands to form a porous 3D MOF, which contains a rhombic channel viewed from the c axis. The detection of various NACs was tested. The fluorescent quenching percentage was showed in Fig. 4(e) and (f), and the number is up to 75% for NP at the concentration being 0.13 mM in DMSO solution. The results showed that the OH^- group in NP, which possible interacts apparently with the emission through electrostatic interactions. As a continue of our research, we also reported a Tb based MOF, $[\text{Tb}_3(\text{NO}_3)(\text{BPTA})_2(\text{H}_2\text{O})_6]\cdot 3\text{Diox}\cdot 8\text{H}_2\text{O}$ (UPC-11, $\text{H}_4\text{BPTA} = [1,1'\text{-biphenyl}]\text{-}2,2',5,5'\text{-tetracarboxylic acid}$, Diox = 1,4-dioxane), which could rapidly and selectively detect NACs. The MOF exhibits luminescent emissions at 290, 545, 584 and 622 nm with the excitation at 330 nm, those peaks are tentatively assigned to $^5\text{D}_4 \rightarrow ^7\text{F}_6$, $^5\text{D}_4 \rightarrow ^7\text{F}_5$, $^5\text{D}_4 \rightarrow ^7\text{F}_4$, $^5\text{D}_4 \rightarrow ^7\text{F}_3$ transitions of Tb^{3+} ion. The luminescent titration show that all NACs can weaken the fluorescence intensity of UPC-11 suspension, but the quenching percentage exhibits a big difference. Meanwhile, the addition of 1,3-DNB, 2,4-DNT, 1,4-DNB, 4-NA, 1-M-4-NB, and 4-NPH solution caused relatively little but similar fluorescent intensity change of suspension, but the introduction of 4-NP produced significant quenching of fluorescence intensity. UPC-11 shows rapid and selective fluorescent sensing properties of NACs, especially for 4-nitrophenol (NP).¹¹

Nitroaromatic explosives with different numbers of –NO₂ groups can be detected in qualitative and quantitative according to Lan and Su's report.⁷⁹ They present a luminescent Ln³⁺@MOF approach to realize a fast and effective Ln³⁺@MOF sensor used to detect nitroaromatic explosives with high recyclability through fluorescence quenching. And the concentrations of complete quenching are about 2000, 1000, and 80 ppm for nitro-benzene, 1,3-dinitrobenzene, and 2,4,6-trinitrophenol, respectively. Meanwhile, to examine the sensing sensitivity toward TNP in more detail, a batch of suspensions of Tb³⁺@NENU-522 were prepared by dispersing it in a DMF solution while gradually increasing the contents to monitor the emissive response. Tb³⁺@NENU-522 displays high selectivity and recyclability in the detection of nitroaromatic explosives. The group also reported NENU-503 for quick and sensitive detection of nitroaromatic explosives through fluorescence quenching.⁵⁹ Notably, the detection of TNT by the MOF can be easily distinguished by the naked eye (Fig. 5). This fluorescence quenching is ascribed to photo-induced electron transfer and resonance energy transfer. For the first time, a MOF can distinguish between NB, 1,3-DNB, and TNP with different numbers of NO₂ groups by the shift of the PL spectra. High stability and recyclability of NENU-503 make it an outstanding candidate in the field of detection of explosives.

(b) Corresponding emission intensities of Tb³⁺@NENU-522 in different concentrations of TNP in DMF. Reprinted with permission from ref 59. Copyright American Chemistry Society 2015.

2.3 Detection in both vapor and solution phase

The detection of NACs can also be operated both in vapor and solution phase. Lu's group reported a 3D luminescent microporous MOF with 1D channels based on triphenylene-2,6,10-tricarboxylate, (Me₂NH₂)₆[In₁₀(TTCA)₁₂]·24DMF·15H₂O (TTCA = triphenylene-2,6,10-tricarboxylate and DMF = N,N'-dimethylformamide)³¹. The framework is of anionic and Me₂NH₂²⁺ cations decomposed from DMF are filled in the channels to balance the charge. The photoluminescence spectrum of framework exhibits strong emission at 505 nm with excitation at 410 nm. The maximum fluorescent intensity of sample was reduced by 41.7, 62.1, 73.5, and 65.9% upon exposure to 2 mM methanol solutions of TNT, 2,4-DNT, 2,6-DNT, and NB, respectively. The compound shows selective sensing of the nitro explosive TNP, making it a promising sensing material for TNP monitoring.

Chen's group developed a fluorescent In based MOF, [In₂L¹²][NH₂(CH₃)₂]₂·(DMF)₄(H₂O)₁₆ (DMF = N,N'-

dimethylformide, $\text{H}_8\text{L}^{12} = \text{tetrakis}[(3,5\text{-dicarboxyphenoxy)methyl]methane}$ with a (4,8)-connected *scu* topology (Fig. 6). $[\text{In}_2\text{L}^{12}][\text{NH}_2(\text{CH}_3)_2]_2(\text{DMF})_4(\text{H}_2\text{O})_{16}$ exhibited a strong fluorescent emission at 360 nm ($\lambda_{\text{ex}} = 280$ nm) at room temperature. On one hand, in vapor phase, the MOF dispersed in DMF was exposure to different concentration ($\text{mol}\cdot\text{L}^{-1}$) of several NACs. The fluorescent intensity reduced by 81.5% of 5×10^{-6} mol/L NB is the most efficient (Fig. 7). The excellent fluorescence quenching response to NACs is due to the electrostatic interactions between the MOF and the electron-deficient NACs. The quenching response is associated with both the electron-withdrawing groups of NACs and the sizes of the pore in MOF. On the other hand, the samples were immersed into DMF solution and several analytes ($0.5 \text{ mol}\cdot\text{L}^{-1}$) were added into the solution. The NACs show inefficient quenching, and the quenching mechanism is similar to those reported by Li's group before.⁵³

In Zhang's work, a multi-responsive sensor with a red-emission signal is successfully obtained by the solvothermal reaction of Eu^{3+} and heterofunctional ligand bpydbH_2 (4,4'-(4,4'-bipyridine-2,6-diyl) dibenzoic acid), followed by terminal-ligand exchange in a single-crystal-to-single-crystal transformation. It can discriminate among the homologues and isomers of aliphatic alcohols and detect highly explosive 2,4,6-trinitrophenol (TNP) in water or in the vapor phase, which may contribute to the electrostatic interactions between free Lewis-base sites and hydroxyl groups in analytes.⁶³

Konar and coworkers reported a 2D Cu(I)-based MOF, $[\text{Cu}(\text{L})(\text{I})]_{2n} \cdot 2n\text{DMF} \cdot n\text{MeCN}$ (**1**); $\text{L}^{23} = 4'-(4\text{-methoxyphenyl})-4,2':6',4''\text{-terpyridine}$; $\text{DMF} = N,N'\text{-dimethylformamide}$, $\text{MeCN} = \text{acetonitrile}$ (Fig. 8), which seems to be the first report of any material which reversibly encapsulates explosive nitroaromatics in vapor phase in single crystal to single crystal fashion with visible color changes without loss of framework integrity (Fig. 9). The MOF also represents one of the best hosts reported so far having extreme stability and selectivity

that meets the benchmark of reversibility for material applications.⁸⁰

Hou and Zang have reported a highly Fluorescent MOF $\{[\text{Tb}(\text{L}^{21})(\text{OH})]\cdot x(\text{solv})\}$ under a combination of hydro/solvothermal and ionothermal conditions.⁷⁵ The fluorescence of that MOF shows high selectivity and sensitivity towards the presence of trace amounts of nitroaromatic analytes in both aqueous and vapor phases, probably through a redox quenching mechanism similar to that in conjugated polymer systems. The origin of the highly selective sensing towards nitroaromatic explosives can be attributed to a photo-induced electron transfer from MOF to nitroaromatic explosives. Further analysis demonstrates that TNP can efficiently quench the fluorescence of the MOF via both electron and long range

energy transfer processes, while other nitroaromatic explosives quench the fluorescence by an electron transfer process only.

2.4 Detection in aqueous phase

In actuality, the detection of nitroaromatics in an aquatic system is highly desirable for practical applications. Ghosh reported a fluorescent porous Zr(IV) based MOF $\text{Zr}_6\text{O}_4(\text{OH})_4(\text{L}^{24})_6$ (**1**, UiO-67@N, H_2L^{24} = 2-phenylpyridine-5,4'-dicarboxylic acid) demonstrate highly selective and sensitive detection of TNP in aqueous media even in the presence of competing nitro analytes (Fig. 10). The guest free MOF was dispersed in water and exhibited strong fluorescence upon excitation at 320 nm. To explore the changes of fluorescence intensity when the different nitro aromatic compounds like TNP, TNT, 2,4-DNT, 2,6-dinitrotoluene (2,6-DNT), 1,3-dinitrobenzene (DNB), NB and 1,3,5-trinitro-1,3,5-triazacyclohexane (nitro-amine RDX) was added. With the incremental addition of TNP to **1'** resulted in fast and high fluorescence quenching (73%) (Fig. 11). Fluorescence quenching can be clearly observed for TNP concentrations of as low as 2.6 mM. At low TNP concentrations a linear increase in the SV plot was observed, which upon and the fitting of the SV plot for TNP gave a quenching constant of $2.9 \times 10^4 \text{ M}^{-1}$, which is amongst the highest values known for MOFs. The occurrence of both electron and energy transfer processes, in addition to electrostatic interaction between the MOF and TNP, contribute to the unprecedented selective fluorescence quenching.⁷⁷ They also reported a hydrolytically stable 3D luminescent metal-organic framework, $[\text{Zn}_8(\text{ad})_4(\text{BPDC})_6\text{O}\cdot 2\text{Me}_2\text{NH}_2]\cdot \text{G}$ (G = DMF and water). The compound in water exhibited a strong emission at 405 nm (λ_{ex} = 340 nm). The emission spectra were recorded by fluorescence titration with different NACs, such as TNP, TNT, 2,4-DNT, and 2,6-DNT. The results showed fast detection and high fluorescence quenching (93 %) for TNP. The MOF can sense TNP at extremely low concentrations, with a detection limit of 12.9 nM.⁷¹ Recently, the same group developed a highly selective and sensitive aqueous phase

detection of NACs, such as 2,4,6-trinitrophenol (TNP) by a water-stable, porous luminescent metal–organic framework, $[\text{Zn}_4(\text{DMF})(\text{Ur})_2(\text{NDC})_4]$ (NDC = 2,6-naphthalenedicarboxylic acid, Ur = urotropin, DMF = *N,N'*-dimethylformamide).⁷⁸

Ionic liquids (ILs) assisted synthesis of MOFs have received increasing attention because their strong polarity improving the reaction conditions of crystalline materials. Hou and Zang group reported two novel lanthanide metal–organic frameworks (Ln-MOFs) $[\text{Ln}(\text{BTB})\text{H}_2\text{O}]$ via ionic liquids method, where Ln = Eu **1**, Tb **2**. **1** and **2** are isostructural and consist of infinite

rod-shaped lanthanide-carboxylate building units which are further bridged by trigonal-planar BTB ligands to give noninterpenetrated open 3D frameworks. The fluorescence properties of **1** and **2** were investigated in water emulsions at 293 K. **1** and **2** both show high selectivity and sensitivity towards the presence of trace amounts of nitroaromatic analytes in the aqueous phase. The emission response was monitored by fluorescence titration with NB, TNP, and 2-NT. The fluorescence quenching efficiency of **1** and **2** increased drastically with the analyte (NB, TNP, and 2-NT). The quenching efficiency can be quantitatively explained by the Stern–Volmer equation, and the calculated K_{sv} values for NB, 2-NT, and TNP were 6.17×10^{-2} , 2.87×10^{-2} , and 6.76×10^{-2} ppm^{-1} for **1**, and 7.54×10^{-2} , 7.46×10^{-2} , and 3.25×10^{-2} ppm^{-1} for **2**, respectively. The fluorescence response mechanism might be attributed to the photo-induced electron transfer from the excited MOF to the electron deficient analytes adsorbed on the particle surface of **1** and **2**.⁷³ Su and Qin group reported a stable luminescent anionic metal–organic framework $[(\text{CH}_3)_2\text{NH}_2]_3\{\text{Zn}_5\text{Na}_2(\text{BPTC})_4\}_n \cdot 4\text{CH}_3\text{OH} \cdot 2\text{DMF}$, which showed highly selective detection of TNP in aqueous solution, which can be attributed to electron transfer mechanisms as well as energy transfer mechanisms.⁷²

2.5 Detection with hybrid MOFs

Qiu have reported a rational self-sacrificing template strategy to obtain tubular nanostructures based on MOF-type materials, and have demonstrated their application for trace-level detection of nitroaromatic explosives. The resultant fluorescent MOFNTs have proven fast, highly sensitive and selective, and reversible for trace-level detection of nitroaromatic explosives, clearly demonstrating that such fluorescent tubular MOF nanostructures can serve as an ideal candidate for fast detection of nitro explosives (Fig. 12).⁸¹

Fig. 12 (a) Illustration of the fabrication process of MOFNTs by the self-sacrificing template strategy. (b) Close-up SEM image of open-ended MOFNTs. (c) Representative TEM image of MOFNTs. Reprinted with permission from ref 81. Copyright the Royal Society of Chemistry 2014.

The same group also successfully fabricated $[\text{Tb}(\text{BTC})]_n$ nanocrystals by a combined ultrasound-vapour phase diffusion method.²⁵ The nanoscale Tb-based MOFs exhibit excellent luminescence properties for the highly selective and sensitive detection of PA, and no obvious interference from other nitroaromatic compounds such as NB, 2-NT, 4-NT, 2,4-DNT and 2,6-DNT, or common organic solvents, was observed.

Qiu's group also tried to combine MOFs with other materials for the explosive detection.⁸² They present novel kinds of $\text{Fe}_3\text{O}_4@\text{Tb-BTC}$ magnetic MOF nanospheres which possess both magnetic characteristics and fluorescent properties using a layer by layer assembly technique. It was applied in detection of nitroaromatic explosives, such as 2,4-dinitrotoluene (2,4-DNT), 2,6-dinitrotoluene (2,6-DNT), 2-nitrotoluene (2-NT), 4-nitrotoluene (4-NT), nitrobenzene (NB) and picric acid (PA). The results indicate that the fluorescence intensity of $\text{Fe}_3\text{O}_4@\text{Tb-BTC}$ can be quenched by all analytes studied in the present work (Fig. 13). Remarkably, the as-synthesized

nanospheres exhibit high sensitivity for 2,4,6-trinitrotoluene (TNT) detection with K_{sv} value of (94800 M^{-1}) . Besides, the magnetic nanospheres can be easily recycled, which makes it more convenient for reutilization and friendly to the environment.

Wang reported the successful preparation of a Mg-based luminescent MIL-53 MOF,⁶⁶ Desolvated this framework can be used as an absorbent for selective adsorption and separation of liquid explosives, including nitroaromatic (nitrobenzene (NB)) and nitroaliphatic (nitromethane (NM) and nitroethane (NE)) compounds, through single crystal-to-single crystal (SC-SC) transformations. On the basis of single crystal analysis, Wang provide direct evidence that both the selective adsorption and fluorescence quenching of the desolvated compound **1a** are dictated by host-guest interactions between guest liquid explosives and the host framework. Such findings differ from those reported in previous works, which were dominated by surficial close contact interactions (Fig. 14).

Fig. 14 Perspective views of the 3D open framework with 1D channel in 1 (with guest DMF molecules) and desolvated 1a; Reversibly selective adsorption of NB (2, in blue), NM (3, in red) and NE (4, in purple) by 1a; Crystals of 1 could be regenerated from 2, 3 and 4 by soaking them in DMF for two weeks at room temperature. Color code for 1: green, Mg; red, O; blue, N; 50% gray, C. Reprinted with permission from ref 66. Copyright the Royal Society of Chemistry 2014.

Mukherjee and coworkers reported three electron-rich MOFs by employing ligands bearing aromatic tags.²⁷ The key role of the chosen aromatic tags is to enhance the π -electron density of the luminescent MOFs. The study has revealed that all of these three prepared MOFs exhibited high selectivity towards explosive nitroaromatics such as DNT, TNT, and TNB over the other electron-deficient aromatics.

3. MOF Film for the NACs sensor

Many signal transduction schemes require a physical interface between the MOF and a device. This generally involves fabricating the MOF as a thin film on a surface. The increasing interest in utilizing MOFs as sensors or as selective membranes has led to a surge of interest in preparing MOF thin films.^{8a, 10}

Most commonly, MOF films have been synthesized directly on the surface of interest from the appropriate molecular and ionic precursors. Typically the surface is a metal, metal oxide, glass, or silicon. Film formation can sometimes be accomplished by simply placing a platform in a reactor with the

MOF precursors. These direct growth approaches often require functionalization of the surface with a self-assembled monolayer or seeding of the growth with small MOF crystals to nucleate film formation. In some cases, MOF films can be grown one molecular or ionic layer at a time by sequential immersions in solutions of the metal and organic precursors.¹⁰ These synthetic methods are typically multiple-step and time-consuming. Moreover, the substrate surfaces in these synthetic procedures need to be either electro-statically compatible or chemically modified upon pretreatment. Fransaer and co-workers reported the flexibility of the electrochemical synthesis of MOFs films is illustrated by the preparation of well-adhering layers of luminescent MOFs on electrically conductive solid substrates (Fig. 15).⁸³ The luminescent layers have been successfully tested for the detection of 2,4-dinitrotoluene (DNT). Similarly A facile electrochemical plating method by means of applying voltage onto zinc electrodes in a BTC electrolyte has been developed to prepare fluorescent MOF films ($\text{Zn}_3(\text{BTC})_2$).⁸⁴ Voltage and fabrication time are found to be the key parameters for the formation and morphology control of MOF films. Additionally, the as-prepared MOF films, due to their evident fluorescence, are explored for potential applications in detecting nitro explosives with detection limit as low as 0.5 ppm. The fluorescent MOF films can be further applied to distinguish nitro explosives by varying the solution concentration. Moreover, the MOF films exhibit excellent reusability in consecutive nitro explosive detection reactions.

Fig. 15 (a) Schematic view of the preparation procedure of $\text{Zn}_3(\text{BTC})_2$ MOF films; (b) quenching percentage of MOF films for different nitro explosive detection methods (0.5 ppm) in ethanol (excited and monitored at 327 nm and 362 nm, respectively); (c) theoretical HOMO and LUMO energies for some nitro explosives. Reprinted with permission from ref 84. Copyright the Royal Society of Chemistry 2014.

A second method for film fabrication is to first synthesize MOF particles and mixed them with other materials to obtain film. This has been demonstrated, for example, in Wen's work, thin films of Zn-MOF/PST-1 with a macroporous network structure were prepared by using electrospinning technique.⁸⁵ The secondary growth technique was developed to strongly anchor Zn-MOF seed crystals on porous supports Zn-MOF/PST-1 to form Zn-MOF/ PST-2 thin films. The MOF films of secondary growth have a good fluorescence quenching sensitivity to the nitroaromatic explosives such as dinitrotoluene(DNT), 2,4,6-trinitrotoluene(TNT), and thus can be good candidates for trace nitroaromatic explosives detection. Jaworski and Jung reported that nanocomposites containing azobenzoic acid functionalized graphene oxide and trans-4,4'-stilbene dicarboxylic acid in the presence of Zn^{2+} have been prepared with various ratios of the two components.⁸⁶ As shown in Fig. 16, the structure of the precursors is preserved in

the composites, where graphene layers from A-GO alternate with layers of MOF structures. The nanocomposites can act as chemosensors for DNT molecule detection.

Fig. 16 (a) Schematic of the proposed bonding between L-Zn^{2+} and A-GO-Zn^{2+} (b) The crystal structure of L-Zn^{2+} showed two different coordination environments which have octahedral and tetrahedral coordination respectively. (c) Its simplified version. (d) Top view of SEM images of nanocomposite 1 layer of A-GO/L-Zn^{2+} (e) Fluorescence quenching of nanocomposite of A-GO/L-Zn^{2+} when exposed to (a) TNT and (b) DNT vapors. (c) Fluorescence quenching of pure crystal L-Zn^{2+} when exposed to DNT vapor. Reprinted with permission from ref 86. Copyright the Royal Society of Chemistry 2013.

An unusual, but useful, third approach involves MOF film formation within the spatial constraints of a gel layer. Lee and Jung reported on the use of a fluorescent MOF hydrogel that exhibits a higher detection capability for TNT in the gel state compared with that in the solution state (Fig. 17).⁸⁷ A portable sensor prepared from filter paper coated by the hydrogel was able to detect TNT at the pictogram level with a detection limit of 1.82 ppt (parts per trillion). It presents a simple and new means to provide selective detection of TNT on a surface or in aqueous solution, as afforded by the unique molecular packing

through the MOF structure in the gel formation and the associated photophysical properties.

4. Conclusions and outlook

In summary, we have briefly reviewed the recent research that is ongoing in the field of LMOFs for sensing NACs, including possible mechanisms for sensing. MOFs are intrinsic candidate for sensing, due to their luminescent and porous qualities, in which, water-stable LMOFs for NACs sensing is a potential development direction, because of the protection of environment and practical applications. As one of the most part of MOFs, it is supposed that the choice of metal ions is also worth discussing. Zn, Na, Mg and Zr ions can be exploited widely instead of Cd and Ni ions. Hundreds of literatures have been reported about LMOFs for NACs sensing, but the study of LMOFs is a new research area. As for NACs, more obvious and simple signal changes can be obtained, such as color changes in

the range of visible light and “naked-eyes” detection. The advantage of LMOFs can also be taken through the post modification or composite with other materials. At the same time, it is much appreciated that preparing the device using stable and efficient MOF material makes the detection process simpler and easier. And it will be an important step in the development process of MOF material in NACs detection.

H ₃ L ¹⁶	4,4',4''-((2,2',2''-(nitro)tris(methylene))tris(1 <i>H</i> -benzo[d]imidazole-2,1-diyl))tris(methylene))tribenzoic acid
H ₃ L ¹⁷	4,4',4''-((2,2',2''-(nitro)tris(methylene))tris(1 <i>H</i> -benzo[d]-imidazole-2,1-diyl))tris(methylene))tribenzoic acid
H ₄ L ¹⁸	bis-(3,5-dicarboxy-phenyl)terephthalamide
H ₃ L ¹⁹	1,3,5-Tri(4-carboxyphenoxy)benzene
H ₂ L ²⁰	2-(2-Hydroxy-propionylamino)-terephthalic acid
H ₂ L ²¹	5-(4-carboxyphenyl)pyridine-2-carboxylat
H ₂ L ²²	2'-amino-[1,1':4',1''-terphenyl]-4,4''-dicarboxylic acid
H ₂ L ²⁴	H ₂ L ²⁴ = 2-phenylpyridine-5,4'-dicarboxylic acid
H ₂ bpdc	4,4'-biphenyldicarboxylic acid
H ₄ BPTA	[1,1'-biphenyl]-2,2',5,5'-tetracarboxylic acid
H ₃ BTB	1,3,5-benzenetrisbenzoic acid
H ₄ BTEC	1,2,4,5-benzenetetracarboxylic acid
H ₂ CPMA	bis(4-carboxyphenyl)- <i>N</i> -methylamine

H ₂ DCPB	1,3-di(4-carboxyphenyl)benzene
Hdmp	3,5-dimethyl-4-(4'-pyridyl)pyrazole
H ₂ MFDA	9,9-dimethyl-fluorene-2,7-dicarboxylic acid
H ₃ NTB	4,4',4''-nitrilotrisbenzoic acid
H ₂ oba	4,4'-oxybis(benzoic acid)
H ₂ PIA	5-(pyridine-4-yl)isophthalic acid
Htba	4-(1 <i>H</i> -1,2,4-triazol-1-yl)benzoic acid
H ₄ TCPPPE	tetrakis[4-(4-carboxyphenyl)phenyl]ethene
H ₃ TPT	<i>p</i> -terphenyl-3,4'',5-tricarboxylic acid
H ₄ ttac	1,1',2'',3''-terphenyl-4,4',5'-tetracarboxylic acid
H ₃ TTCA	Triphenylene-2,6,10-tricarboxylic acid
H ₃ TTPB	1,3,5-tri(4-(2 <i>H</i> -tetrazol-5-yl)phenoxy)benzene
ad	adenine
BDC	benzene-1,4-dicarboxylate
bimb	4,4'-bis(1-imidazolyl)biphenyl
bpe	1,2-bis(4-pyridyl)ethane
bpeb	1,4-bis[2-(4'-pyridyl)ethenyl]benzene
bpee	1,2-bis(4-pyridyl)ethylene
BPNO	4,4'-dipyridyl- <i>N,N'</i> -dioxide
bpp	1,3-bis(4-pyridyl)propane
BPTC	biphenyl-3,3',5,5'-tetracarboxylic acid
bpy	4,4'-bipyridine
bpydbH ₂	4,4'-(4,4'-bipyridine-2,6-diyl)dibenzoic acid
dcbpy	2,2'-bipyridine-4,4'-dicarboxylate
DEF	<i>N,N'</i> -diethylformamide
D-H ₂ cam	D-camphor acid
Diox	1,4-dioxane
dipb	4,4'-di(1 <i>H</i> -imidazol-1-yl)-1,10-biphenyl
DMA	<i>N,N'</i> -dimethylacetamide
DMF	<i>N,N'</i> -dimethylformamide
DMSO	Dimethyl sulphoxide
dpb	1,4-di(4-pyridyl)benzene
dpe	1,2-di(4-pyridyl)ethylene
dpyb	1,4-di(pyridin-4-yl)benzene
en	1,2-ethanediamine
fdc	2,5-furandicarboxylate dianion
IPA	isophthalic acid
G	guest solvent molecules
L ²³	4'-(4-methoxyphenyl)-4,2':6',4''-terpyridine
<i>m</i> -DNB	1,3-Dinitrobenzene
NB	Nitrobenzene
NDC	2,6-naphthalenedicarboxylic acid
NMP	1-methyl-2-pyrrolidone
NT	2-Nitrotoluene
PA	Picric acid
PAM	4,4'-methylenbis(3-hydroxy-2-naphthalenecarboxylate)
PCA	4-pyridinecarboxylic acid
<i>p</i> -DNB	1,4-Dinitrobenzene
ppvppa	<i>N</i> -(pyridin-2-yl)- <i>N</i> -(4-(2-(pyridin-4-yl)vinyl)phenyl)pyridin-2-amine
PPZ	piperazine
sdb	4,4'-sulfonyldibenzoate
TATAB	4,4',4''-s-triazine-1,3,5-triyltri- <i>p</i> -aminobenzoate
TCA	tri-carboxytriphenylamine

TDPAT	2,4,6-tris(3,5-dicarboxyl phenylamino)-1,3,5-triazine
ted	triethylenediamine
TNT	2,4,6-trinitrotoluene
TPTZ	{4-[4-(1 <i>H</i> -1,2,4-triazol-1-yl)phenyl]phenyl}-1 <i>H</i> -1,2,4-triazole
