29 **Abstract:** a simple and facile solvothermal method is developed for the preparation of
30 reduced graphene oxide/NH₂-MIL-125(Ti) (rGO-NMTi) hybrid nanocomposite
31 photocatalysts with large specific surface area and thermal stability. This
32 rGO-NMTi-x hybrid nanocomposite exhibited more efficient photocatalytic
33 performance than NH₂-MIL-125(Ti) for methyl blue (MB) degradation under
34 visible-light irradiation due to the synergetic action between rGO and
35 NH₂-MIL-125(Ti). Therefore, rGO/MOFs photocatalysts have great potentiality in
36 environmental remediation. The structure and physical properties of rGO,
37 NH₂-MIL-125(Ti) and rGO-NMTi-x hybrid nanocomposites were characterized by
38 means of scanning electron microscopy (SEM), X-ray diffraction (XRD), N₂
39 adsorption/desorption, high resolution transmission electron microscope (HRTEM),
40 laser Raman, UV-visible absorption spectra (UV-DRS) and FT-IR techniques.

54 **1. Introduction**

55 As an environmentally friendly and cost-effective technology, visible light driven
56 photocatalysis for removal of organic pollutant has been extensively studied.¹⁻³ The
57 photocatalytic activity of the photocatalysts with nanostructure depends strongly on
58 their composition and structure.⁴⁻⁶ The main serious obstacles in developing hybrid
59 photocatalysts are including poor affinity between pollutants and photocatalyst,⁷ rapid
60 recombination of photogenerated electron-hole pairs,⁸ low-light-harvesting efficiency
61 of photocatalyst,⁹ and short light residence time on/in the photocatalysts.^{10,11}
62 Metal-organic frameworks (MOFs), a novel class of hybrid materials constructed by
63 metal-containing nodes connected by organic bridges, have attracted a great deal of
64 attention due to their useful applications in gas storage, separation, catalysis, sensors,
65 and other technologies.¹²⁻¹⁵ However, the performance of MOFs served as catalysts in
66 photocatalysis is not comparable to that of inorganic semiconductors due to the low
67 efficiency for solar energy conversion and photo-generated charge separation.
68 Hybrid material, a novel mixture of material has attracted a great deal of attention due
69 to the exciting properties compared with pure counterparts.^{16,17} Compared with pure
70 MOFs, the hybrids integrating MOFs with inorganic species (CdS, TiO₂, Fe₃O₄, Cu₂O,
71 Au, Pd, and Pt) acted as photocatalysts presented significant advantages than the pure
72 MOFs, owing to their synergism effect.¹⁸⁻²⁴ He *et al.* reported that the photocatalytic
73 hydrogen production efficiency of CdS-MIL-101 hybrid materials under visible-light
74 irradiation was superior to pure CdS nano-particles owing to photocatalytic reaction
75 centers with high visible light harvesting capability, more active adsorption sites, and

76 high specific surface area.¹⁸ Thus, far much attention has been focused on
77 carbon-based materials, which contains a lot of prospective materials such as,
78 graphene quantum dots (QDs),²⁵ graphene,^{26,27} fullerene,²⁸ and carbon nanotubes.²⁹
79 All of them are extensively used as catalyst owing to their large specific surface area,
80 excellent mechanical and hydrophobic properties as well as chemically stability. In
81 addition, graphene exhibits several photocatalyst properties,³⁰⁻³⁵ including the
82 extension of the duration of electron-hole pair, the enhancement of light adsorption
83 range and intensity. According to the report of Qiu *et al*,³⁶ TiO₂/graphene composites
84 with high electrical conductivity and three-dimensional hierarchically porous structure
85 prepared by one-step method exhibits potential photoactivity. Gan *et al*³⁷ studied the
86 P25/graphene composite in degrading aquatic organic pollutants and discussed the
87 contribution of photothermal effect in the photocatalytic performance.³⁸ Zhang *et al*
88 and Wu *et al*³⁹⁻⁴¹ reported the MIL-88(Fe)@GO and the GR/MIL-53(Fe)-H₂O₂
89 photocatalytic materials, respectively for the degradation of dye or Rhodamine B.
90 However, NH₂-MIL-125(Ti), as a highly porous MOFs photochemical property, not
91 only contained high density of the immobilized Ti sites, but also presented
92 isostructural MOFs with improved photocatalytic properties by tuning the
93 incorporation of organic ligands. Therefore, the reduced graphene oxide/NH₂-MIL-
94 125(Ti) (rGO-NMTi) hybrid materials were designed and synthesized by a simple and
95 facile solvothermal method. Its photocatalytic activity towards methyl blue (MB) dye
96 degradation under visible-light irradiation was evaluated. The photocatalytic
97 mechanism as well as the reusability and stability of photocatalyst, an

98 environmental-friendly optimizing hybrid nanocomposite were investigated. The
99 structure and physical properties of hybrid nanocomposite photocatalysts were
100 characterized by means of SEM, HRTEM, Laser Raman, XRD, FT-IR, N₂
101 adsorption–desorption, and UV–vis DRS techniques.

102 **2. Experimental**

103 **2.1. Materials**

104 Sodium nitrate, hydrochloric acid, hydrogen peroxide (30%), barium chloride,
105 sulfuric acid and potassium permanganate were purchased from Shantou Xilong
106 chemical Co., Ltd, China. Graphite powder was received from Sinopharm Chemical
107 Regent. 2-amino-benzene-1,4-dicarboxylate (NH₂-BDC) and tetra-n-butyl titanate
108 Ti(OC₄H₉)₄ (TPOP) were purchased from Alfa Aesar Co., Ltd, China and Shanghai
109 Chemical Reagent Co., Ltd, China, respectively. These reagents were analytical grade
110 and used without further purifications.

111 **2.2 Synthesis of GO and rGO/NH₂-MIL-125(Ti) hybrid materials**

112 Graphite oxide (GO) was prepared according to the methods in literature.⁴² The
113 NH₂-MIL-125(Ti) was synthesized according to the previously reported method with
114 slight modification.⁴³ A certain amount of GO powder was dispersed into methanol
115 with the aid of ultrasonication. Then, TPOP (2.3 mL), NH₂-BDC (2.1 g), DMF (35
116 mL), and GO-methanol (4.0 mL) mixture was subjected to solvothermal conditions in
117 a Teflon-lined stainless-steel autoclave. The resulting solution was treated by
118 ultrasonic for 15 min to obtain a uniformly dissolution of the reactants, and then kept
119 at 120 °C for 48 h. After reaction, the resultant precipitate was separated by

120 centrifugation, washed repeatedly with DMF and methanol, respectively. Finally, the
121 as-obtained hybrid materials were dried at 100 °C under vacuum for 24 h. As-obtained
122 precipitant were denoted as rGO-NMTi-1, rGO-NMTi-2, rGO-NMTi-3, and
123 rGO-NMTi-4, where 1, 2, 3 and 4 represent the 5, 10, 15 and 20 wt% of GO in the
124 samples, respectively. For comparison purposes, the conventional NH₂-MIL-125(Ti)
125 was prepared in the absence of GO under the same conditions.

126 **2.3 Characterization**

127 Morphology of the samples was characterized by a scanning electron microscopy
128 (SEM) on a Gemini microscope (Hitachi, S-4800, Japan) at an accelerating voltage of
129 10 kV. X-ray diffraction (XRD) patterns were collected on a Panaltical X'Pert-pro
130 MPD X-ray power diffractometer (Cu K α irradiation source, $\lambda = 1.54056 \text{ \AA}$).
131 UV-visible absorption spectra (UV-DRS) of the hybrid nanocomposites were
132 obtained for the dry-pressed disk samples using a Cary 500 Scan Spectrophotometer
133 (Varian, USA). The IR experiments were carried out on a Nicolet 670 FT-IR
134 spectrometer in the range of 4000-400 cm⁻¹. Transmission electron microscope (TEM)
135 was conducted on FEI Tecnai G2 S-TWIN and the accelerating voltage was 200 kV.
136 Raman spectroscopy was measured on Renishaw inVia plus using 633 nm laser
137 excitation (Microplate reader: Biocell HT2). Brunauer-Emmett-Teller (BET) surface
138 area of the samples was measured using a sorptometer (ASAP-2420, Micromeritics,
139 USA) at 77 K.

140 **2.4 Photocatalytic evaluation**

141 Photocatalytic degradation of methyl blue (MB) was carried out in a 100 mL beaker

142 containing 40 mL of methyl blue solution (5.4×10^{-5} mol/L) and photocatalyst (30 mg).
143 The solution was stirred magnetically in a dark room for 20 min to get
144 adsorption–desorption equilibrium. The solution was then irradiated under
145 visible-light illumination (> 420 nm). A 300 W Xenon lamp (Beijing China Education
146 Au-light, Co. Ltd.) with a 420 nm cutoff filter was used as the visible-light source. At
147 certain time intervals, 4 mL of aliquots were sampled and centrifuged to remove the
148 photocatalyst. The MB concentration was determined using a UV–vis
149 spectrophotometer at the wavelength of 663 nm. The degradation rate was calculated
150 using below equation.

$$151 \quad \text{Degradation rate} = (C_0 - C) \times 100\% / C_0$$

152 C_0 and C are the MB concentrations before and after visible light photodegradation,
153 respectively.

154 **3. Results and discussion**

155 **3.1. Morphology and structure of rGO-NMTi-x hybrid materials**

156 The morphologies of rGO-NMTi-x were clearly observed by scanning electron
157 microscopy (SEM), and SEM images of GO and $\text{NH}_2\text{-MIL-125(Ti)}$ are also shown in
158 Fig. 1 for comparison. It can be seen that the GO presented a sheet structure with
159 wrinkle (Fig. 1a) whereas the morphology of $\text{NH}_2\text{-MIL-125(Ti)}$ (Fig. 1b) looks like
160 the snowflake or cotton with some traces of amorphous phase. After a certain amount
161 of GO powder was introduced during the synthesis, the SEM image of rGO-NMTi-x
162 (Fig. 1c-f) revealed that the particles of $\text{NH}_2\text{-MIL-125(Ti)}$ agglomerated slight with
163 different surface morphology. Moreover, the agglomerates of rGO-NMTi-1

164 nanocomposite look different from pure NH₂-MIL-125(Ti). The sandwich-like
165 structure between NH₂-MIL-125(Ti) and rGO is not clearly in rGO-NMTi-1 due to
166 low resolution. It is very possible that the introduction of more GO interfere with the
167 NH₂-MIL-125(Ti) crystal, which are even more visible for rGO-NMTi-3 (with 15
168 wt% GO) and the particles of NH₂-MIL-125(Ti) become larger with incremental GO
169 loadings (Fig. 1f).

170

171

Fig. 1.

172 The powder XRD patterns of rGO, NH₂-MIL-125 (Ti) and rGO-NMTi-x are
173 shown in Fig. 2, it can be seen that there is a broad peak at $2\theta = 26^\circ$, a typical
174 character of amorphous carbon or graphene for rGO sample. In the meantime, the
175 NH₂-MIL-125(Ti) presented a typical structure of inorganic crystal (Fig. 2b), which
176 are consistent with the result reported previously,⁴³ demonstrating that preparation of
177 rGO and NH₂-MIL-125(Ti) are successful. Interestingly, for the hybrid composites,
178 rGO-NMTi-x, a broad peak at $2\theta = 26^\circ$ reduced slightly compared to that of rGO but
179 these peaks intensified with an increasing GO content (Fig. 2c-f), indicated that the
180 amorphous structure of rGO existed in rGO-NMTi-x samples. According to the report
181 of Hafizovic *et al*,⁴⁴ the presence of carboxylic groups on the surface of rGO would
182 result in a distortion of the cubic symmetry. Hence, the characteristic peaks of
183 NH₂-MIL-125(Ti) reduced or/and disappeared in the rGO-NMTi-x hybrid
184 nanocomposites (Fig. 2c-f) due to the differences in the building units of
185 rGO-NMTi-2 and the other hybrid nano-composites. It is well known that the
186 structure of both GO and NH₂-BDC is π -rich, there should be strong π - π interactions

187 between them. Therefore, the presence of GO sheets may unusually bend the
188 $\text{NH}_2\text{-BDC}$ linker and results in severe twisting of the $\text{TiO}_5(\text{OH})$ paddle wheel from an
189 ideal octahedral square grid. Due to this distortion, the $\text{NH}_2\text{-MIL-125}(\text{Ti})$ crystals
190 would exist in a body centered unit cell instead of a primitive cell with symmetry.^{45,46}
191 Therefore, the introduction of GO can affect the crystallization of $\text{NH}_2\text{-MIL-125}(\text{Ti})$
192 and control the morphology of such heterostructures.

193

194

Fig. 2.

195

196 **3.2 FT-IR spectra, UV-vis DRS and specific surface area of the hybrid materials**

197 Figure 3 showed the FT-IR spectra of rGO, $\text{NH}_2\text{-MIL-125}(\text{Ti})$ and rGO-NMTi
198 hybrid nanocomposites in the range of $500\text{--}4000\text{ cm}^{-1}$. It can be seen that a broad
199 peak at 3400 cm^{-1} can be attributed to the O-H vibration of H_2O in the FT-IR
200 spectrum of GO. The absorption bands of C=O and C-O were observed at 1718 and
201 1250 cm^{-1} in the spectrum of $\text{NH}_2\text{-MIL-125}(\text{Ti})$ and rGO-NMTi-x hybrid
202 nanocomposites. Moreover, $\text{NH}_2\text{-MIL-125}(\text{Ti})$ and rGO-NMTi-x hybrid nano-
203 composites present characteristic bands of the carboxylate in $1380\text{--}1600\text{ cm}^{-1}$ as well
204 as the vibrations of O-Ti-O groups at $400\text{--}800\text{ cm}^{-1}$. These results verified further that
205 the solvothermal synthesis of rGO-NMTi-x hybrid nanocomposites still maintained
206 intact MOF structure of $\text{NH}_2\text{-MIL-125}(\text{Ti})$.

207

208

Fig. 3.

209

210 The UV–vis DRS analysis of rGO-NMTi-x hybrid nanocomposites was conducted on
211 a Cary 500 scan spectrophotometer. As shown in Fig. 4, a notable absorption
212 extension in the visible-light region can be observed for rGO-NMTi-x hybrid
213 nanocomposites and the optical absorption intensity enhances with the increase of
214 rGO contents. According to the report of Fu *et al.*,⁴³ there was absorption peak at 250
215 nm with absorption edge to 350 nm for MIL-125(Ti) whereas NH₂-MIL-125(Ti)
216 showed an extra absorption band at 400 nm with the absorption edge extending to ca.
217 550 nm, which originated from the induction effect of an amino functionality for its
218 optical absorption, in agreement with our observation (Fig.4 a-b). However, it is of
219 interest to note that a notable absorption extension band is observed (Fig.4c-d) in the
220 visible-light region when the content of rGO was more than or equal to 15% in
221 rGO-NMTi-x hybrid nanocomposites. According to Zhang *et al.*⁴¹ for GR/MIL-53(Fe)
222 composites, the optical absorption intensity in the range 500–800 nm increased
223 remarkably after combination with appropriate amount of GR, which attributed to the
224 background absorption of GR. We considered that the GO underwent quick
225 deoxygenation (removal of epoxide and hydroxyl functional groups), which reflected
226 enhanced π -electron conjugation and structural ordering with the restoration of sp²
227 carbon and possible rearrangement of atoms. FT-IR of rGO-NMTi-x (Fig. 3d and 3e)
228 also confirmed that the vibration spectra of C=O changed obviously which correlated
229 closely with energy band gap structure⁴⁷. In the meantime, the change in color is
230 accompanied from dark green of rGO-NMTi-2 to grey black of rGO-NMTi-3 (inset in
231 Fig. 4.), in agreement with previous observations in other rGO based composites.⁴¹ It

232 indicated that the synergetic action between rGO and NH₂-MIL-125(Ti) can reduce
233 successfully the recombination rate of the electron-hole pair in the rGO-NMTi hybrid
234 nanocomposites. The red shift of absorption wavelength suggested that these
235 nanocomposites can absorb effectively visible-light for the application in the
236 visible-light photocatalysis.⁴⁸

237

238

Fig. 4.

239 To further identify structural properties of the rGO-NMTi composites, Fig. 5a and
240 5b illustrated HRTEM images of rGO-NMTi-3; it can be seen that the irregular ball
241 nanoparticles of NH₂-MIL-125(Ti) are embedded in the wrinkling rGO lamellar
242 structure and its morphology is similar to the observation from SEM of samples (Fig.1)
243 which is different entirely from the rod-shaped structure of MIL-88(Fe)@GO reported
244 in literature³⁹⁻⁴⁰. In addition, there were two typical peaks, *G* at 1595 cm⁻¹ and *D* at
245 1325 cm⁻¹ in Raman spectrum of rGO-NMTi-3 composite (Fig. 5c), meaning the
246 existence of rGO in rGO-NMTi-3. According to the report of Li *et al.*,⁴⁹ The *G* peak is
247 associated with the first-order scattering of E_{2g} mode for sp² hybridized carbon
248 domain and the *D* peaks are assigned to the structural defects corresponding to
249 sp³ hybridization. Furthermore, the ratio of I_D and I_G was 1.05, indicating the efficient
250 reduction of GO during solvothermal process. The abroad peaks appeared at about
251 1063, 856, 652, and 463 cm⁻¹ are corresponding to the characteristic vibrations of
252 metal terephthalate (Fig. 5c), similar to the observation in MIL-53(Fe)[H₂O].⁴⁰

253 As shown in Fig. 5d, the N₂ adsorption/desorption isotherms observed over

254 rGO-NMTi-3 and NH₂-MIL-125(Ti) attributed to IV-type adsorption curve. It can be
255 seen that the adsorption contents at pressure range of $p/p_0 = 0.05-0.3$ increased
256 remarkably, meaning the existence of a large amount of micropores in
257 NH₂-MIL-125(Ti) whereas when the pressure range of p/p_0 is more than 0.4, both
258 adsorption capacities almost kept at a constant. The shape of hysteresis loop between
259 adsorption and desorption branches illustrated the existence of slit-pores in the
260 rGO-NMTi-3, which consisted of micro- and meso-pore. The specific surface areas of
261 rGO-NMTi-3 and NH₂-MIL-125(Ti), calculated *via* Brunauer-Emmett-Teller (BET)
262 method are 750.3 and 1233 m² g⁻¹, respectively.

263

264 Fig. 5.

265

266 3.3 Photocatalytic performance of rGO-NMTi-x

267 The photocatalytic activities of the as-synthesized NH₂-MIL-125(Ti) and
268 rGO-NMTi-x hybrid nano-composites were evaluated *via* the photodegradation of
269 MB under visible light irradiation (> 420 nm), as shown in Fig. 6. It can be seen that
270 there is not the photodegradation of MB to occur in the absence of photocatalyst
271 (Fig.6a) whereas all of rGO-NMTi-x photocatalysts show much higher photocatalytic
272 activities than NH₂-MIL-125(Ti) for the photodegradation of MB under the same
273 experimental conditions due to the synergistic effect between NH₂-MIL-125(Ti) and
274 rGO. However, when the rGO content increased to 20 wt% there was a slight decrease
275 in photocatalytic activity (Fig. 6e), which is still better photocatalytic performance of
276 NH₂-MIL-125(Ti) due to the fact that the higher contents of rGO in the rGO-NMTi-x

277 hybrid nanocomposites will result in an redundant ratio between rGO and
278 NH₂-MIL-125(Ti), thereby lowering the electron transfer efficiency of the
279 photoinduced electrons on NH₂-MIL-125(Ti) to rGO surfaces. We may envisage that
280 the photocatalytic activity of rGO-NMTi-4 declines with much higher loading in the
281 composite photocatalyst under visible light irradiation. This result indicates that both
282 rGO and NH₂-MIL-125(Ti) play an important role in improving the photocatalytic
283 activity due to the significant synergistic effect between rGO and NH₂-MIL-125(Ti)
284 for the photodegradation of MB under visible light irradiation.

285

286

Fig. 6.

287

288 **3.4. Clarification of the reaction mechanism.**

289 It is well known that high adsorption ability, an efficient charge migration, and
290 large surface area play a vital role for improving the photocatalytic activity.⁵⁰ The
291 existence of rGO sheets could facilitate charge migration and reduce the
292 recombination of electron-hole pairs of the rGO based photocatalysts.⁵¹ Here, a
293 possible photocatalytic process is schematized in Fig. 7. The photo-generated
294 electrons originated from MB or rGO transfer to the Ti⁴⁺ in the titanium-oxo clusters
295 of NH₂-MIL-125(Ti) due to the adsorption or the heterojunction structure, Ti⁴⁺ is thus
296 reduced to Ti³⁺. Oxygen molecules adsorbed onto porous NH₂-MIL-125(Ti) to form
297 superoxide ($\bullet\text{O}^{2-}$) ion radicals *via* electron transfer from Ti³⁺ to O₂ molecules due to
298 the strong reducing ability of Ti³⁺. The Ti³⁺ ions are oxidized and further convert to

299 Ti^{4+} ions. The electron transportation in the titanium–oxo clusters of $\text{NH}_2\text{-MIL-125(Ti)}$
300 *via* the presence of $\text{Ti}^{3+}\text{-Ti}^{4+}$ intervalence electron transfer had been verified by
301 previous reports.⁴³ The formed $\cdot\text{O}^{2-}$ radicals could efficiently degrade MB (or $\text{MB}^+\cdot$)
302 into CO_2 and water. Simultaneously, the generated holes of rGO are capable of
303 oxidizing MB directly.⁵²

304

305

Fig. 7.

306

307 **3.5. Recyclability and stability of rGO-NMTi-3**

308 The recycle experiments of rGO-NMTi-3 for photocatalytic reaction were carried
309 out under the condition of visible-light irradiation to evaluate the stability of the
310 photocatalyst. As shown in Fig. 8a, the efficiency for the photodegradation of MB
311 after 5th-runs are still kept above 96.7%, indicating that the rGO-NMTi-3 can be used
312 successively without the variation of photocatalytic performance during the oxidation
313 of pollutant. The HRTEM images, XRD and Raman results of rGO-NMTi-3 before
314 and after 5th-runs (Fig. 5a-c and Fig. 8b-d) revealed the high stability of the
315 rGO-NMTi-3 photocatalyst in the structure and composition. Therefore, rGO-NMTi-3
316 hybrid nano-composites can be used as efficient visible-light photocatalyst for
317 application in wastewater treatment.

318

Fig. 7.

319

320 **4. Conclusion**

321 A series of rGO-NMTi-x hybrid nanocomposites with large surface area, high
322 activity and stability were successfully synthesized by means of a simple
323 solvothermal strategy where rGO acted as the support for the formation of
324 heterostructures. The results indicated that the rGO-NMTi-3 hybrid nanocomposites
325 showed remarkably higher photocatalytic performance for the degradation of MB than
326 NH₂-MIL-125(Ti) under the condition of visible-light irradiation due to the
327 synergistic effect between NH₂-MIL-125(Ti) and rGO as well as the Ti³⁺-Ti⁴⁺
328 intervalence electron transfer. Furthermore, the rGO-NMTi-3 hybrid nanocomposites
329 can be used as efficient visible-light photocatalyst for application in wastewater
330 treatment in the near future.
