## Iron(II)-catalyzed asymmetric intramolecular olefin aminochlorination using chloride ion†

Cheng-Liang Zhu,‡<sup>a</sup> Jun-Shan Tian,‡<sup>a</sup> Zhen-Yuan Gu,<sup>ab</sup> Guo-Wen Xing<sup>b</sup> and Hao Xu\*<sup>a</sup>

An iron-catalyzed enantioselective and diastereoselective intramolecular olefin aminochlorination reaction is reported (ee up to 92%, dr up to 15:1). In this reaction, a functionalized hydroxylamine and chloride ion are utilized as nitrogen and chlorine sources, respectively. This new method tolerates a range of synthetically valuable internal olefins that are all incompatible with existing asymmetric olefin aminochlorination methods

#### Introduction

Enantioselective olefin halo-functionalization reactions constitute a range of synthetically valuable yet challenging transformations.1 Although a variety of excellent asymmetric olefin halo-oxygenation reactions have been discovered,2 there are much fewer asymmetric olefin aminohalogenation methods available.3 In particular, there have been just a few reported catalytic asymmetric olefin aminochlorination reactions.4 In one instance, Feng discovered the chiral Lewis acid-catalyzed aminochlorination of chalconic and other α,β-unsaturated olefins. 4a,c Also, Chemler reported copper-catalyzed aminochlorination of terminal olefins with chlorine radical donors in the presence of MnO2 (Scheme 1A).4b Despite these and other important discoveries, catalytic asymmetric aminochlorination methods for internal, non-chalconic olefins have yet to be developed. These methods would be synthetically valuable because they would readily provide vicinal amino chlorides, a class of important chiral building blocks. Moreover, asymmetric olefin aminochlorination that proceeds through an ironnitrenoid intermediate has not yet been reported.5

We previously discovered Fe(BF<sub>4</sub>)<sub>2</sub>-based catalysts for both diastereoselective and enantioselective intramolecular olefin aminofluorination reactions.<sup>6</sup> Our initial attempts to apply these catalysts to olefin aminochlorination reactions led to either low diastereoselectivity or low yield, presumably due to the reason that chlorine and fluorine atom-transfer may proceed through

distinct mechanisms. Therefore, we explored a range of acti-

vating group-ligand combinations and discovered entirely new

Prior to this research, Bach reported an FeCl<sub>2</sub>-catalyzed racemic intramolecular olefin aminochlorination method using acyl azides, TMSCl, and EtOH under ligand-free conditions.<sup>7</sup>

B) current work: iron-catalyzed asymmetric aminochlorination of internal olefins with chloride ion

Scheme 1 Catalytic asymmetric olefin aminochlorination: summary of this work and other existing asymmetric methods.

catalytic conditions for asymmetric olefin aminochlorination. Herein, we describe iron-catalyzed enantioselective and diastereoselective intramolecular aminochlorination for a range of internal, non-chalconic olefins (ee up to 92%, dr up to 15:1). In these reactions, a functionalized hydroxylamine and chloride ion were utilized as nitrogen and chlorine sources, respectively. This method tolerates a range of synthetically valuable internal olefins that are all incompatible with existing asymmetric olefin aminochlorination approaches; it also provides a new approach that is complementary to known methods for the asymmetric synthesis of amino chlorides with contiguous stereogenic centers.

<sup>&</sup>lt;sup>a</sup> Unless stated otherwise, the reactions were carried out under a nitrogen atmosphere. TBAC: tetra-*n*-butylammonium chloride. <sup>b</sup> Conversion and dr were determined by <sup>1</sup>H NMR. <sup>c</sup> Isolated yield.

Excellent syn-selectivity was observed with styrenyl olefins (dr up to > 20:1). However, poor diastereoselectivity was recorded with non-styrenyl acyclic olefins (dr: 1:1). The new method presented here has a few unique features which complement the existing iron-catalyzed olefin amino-chlorination method. First, excellent anti-selectivity has been observed across a wide range of styrenyl and non-styrenyl olefins. Second, good to excellent enantioselectivity has been achieved with a variety of internal, non-chalconic olefins (ee up to 92%). Finally, acyl azides are non-reactive under the described reaction conditions (*vide infra*), which suggests that iron-nitrenoid generation may proceed *via* different pathways compared with the known azide activation pathway.

#### Results and discussion

A cinnamyl alcohol-derived acyloxyl carbamate 1 was selected as the model substrate for catalyst discovery (Table 1).8 In the presence of tetra-n-butylammonium chloride (TBAC), we observed that  $FeCl_2$  alone catalyzed a sluggish reaction under ligand-free conditions (entry 1, 45% yield, dr: 2:1).9 However, the  $FeCl_2$ -phenanthroline (L1) complex catalyzed the anti-

**Chemical Science Edge Article** 

aminochlorination with significantly improved yield and dr (entry 2, 80% yield, dr > 20:1). We also noted that the Fe(NTf<sub>2</sub>)<sub>2</sub>-L1 complex provided essentially the same reactivity and diastereoselectivity (entry 3, 86% yield, dr > 20:1). Interestingly, the Fe(NTf<sub>2</sub>)<sub>2</sub>-bisoxazoline (L2) complex resulted in a loss of diastereoselectivity (entry 4, 82% yield, dr: 0.83:1). Furthermore, the Fe(NTf<sub>2</sub>)<sub>2</sub>-L3 complex promoted the synaminochlorination with moderate yield and dr (entry 5, 34% yield, dr: 0.25:1). We also observed that the Fe(NTf<sub>2</sub>)<sub>2</sub>-L4 complex catalyzed the anti-aminochlorination with a modest dr (entry 6, 75% yield, dr: 1.8:1). Notably, an iron-L4 complex resulted in high dr and reaction rate in the previously reported olefin aminofluorination reaction.6 These observations suggest that ligands are involved in the diastereoselectivity-determining step and provide excellent opportunities for diastereo-control.

The observed ligand-enabled diastereo-control with transolefin 1 prompted us to evaluate cis-olefin 1' (Scheme 2). To our surprise, the Fe(NTf<sub>2</sub>)<sub>2</sub>-L1 complex catalyzed syn-aminochlorination, while the Fe(NTf2)2-L4 complex promoted antiaminochlorination with essentially the same dr (Scheme 2). The different reaction profiles for isomeric olefins 1 and 1' suggest that the aminochlorination reaction is neither stereospecific nor fully stereo-convergent, which is significantly different from the iron-catalyzed olefin aminofluorination reaction.<sup>6</sup>

Furthermore, an acyl azide 3 was evaluated under the reaction conditions as a control experiment. Interestingly, the acyl azide 3 was fully recovered and no aminochlorination product was detected. These results suggest that the activation of acyloxyl carbamates (1 and 1') may proceed via different pathways compared with the known azide activation pathway.7

We subsequently explored a range of olefins under the optimized conditions to evaluate the scope and limitations of this anti-aminochlorination method (Table 2). We discovered that di-substituted styrenyl olefins are generally good substrates; both electron-donating and electron-withdrawing substituents are compatible with this method (entries 1-4). Importantly, ortho-substituents and pyridyl groups are both tolerated (entries 5-6). Furthermore, extended aromatics, including naphthyl olefins, are reasonable substrates (entries 7-8). Moreover, isomeric ene-ynes are both excellent substrates for the stereo-convergent and anti-selective method (entry 9). Additionally, we observed that both styrenyl and non-styrenyl tri-substituted olefins undergo aminochlorination smoothly with excellent dr (entries 10-11).10 We also discovered that a cyclohexyl-substituted olefin was an excellent substrate (entry 12, dr > 20:1). Further exploration revealed that both 1,1-disubstituted olefins and dienes are viable substrates with excellent regioselectivity (entries 13-14). Most notably, a cyclic olefin could also undergo highly diastereoselective anti-aminochlorination (entry 15, dr > 20:1), yielding a product which is difficult to obtain with known methods.11 Since the FeCl2-L1 complex provides essentially the same dr and yield in these diastereoselective reactions, FeCl2 can be a convenient substitute for Fe(NTf<sub>2</sub>)<sub>2</sub> in racemic reactions.

Catalyst discovery for the iron-catalyzed asymmetric olefin aminochlorination reaction

<sup>&</sup>lt;sup>a</sup> Unless stated otherwise, the reactions were carried out under a nitrogen atmosphere with 4 Å molecular sieves. <sup>b</sup> Reaction conditions: Boc<sub>2</sub>O, Et<sub>3</sub>N, DMAP; then Cs<sub>2</sub>CO<sub>3</sub>, MeOH, 85% over two steps; see ESI for details. <sup>c</sup> Conversion and dr were determined by <sup>1</sup>H NMR. <sup>d</sup> Isolated yield. <sup>e</sup> Enantiomeric excess (ee) was measured by HPLC with chiral columns; the absolute stereochemistry was determined by X-ray crystallographic analysis of an analog of 2a. The reaction was carried out at -60 °C for 12 h. The FeCl<sub>2</sub>-L5 complex was used.

In order to fulfil the need for catalytic asymmetric olefin aminochlorination, we further explored asymmetric induction for internal, non-chalconic olefins with a variety of iron-chiral ligand complexes (Table 3).12 First, we discovered that the iron-L5 complex induced diastereoselective and enantioselective anti-aminochlorination, albeit with a low yield, mostly due to the competing aminohydroxylation reaction (entry 1, 53% yield, dr: 9.9:1). Interestingly, the anti-addition product 2a was obtained with excellent ee (84% ee), while the syn-addition product 2b was obtained essentially as a racemate (<5% ee).13 Additionally, a two-step procedure can convert 2a to a chlorinated amino alcohol triad 4 without ee erosion.14 Next, we observed that the iron-L6 complex induced moderately diastereoselective syn-aminochlorination (entry 2, 68% yield, dr: 0.48:1). To our surprise, the anti-addition product 2a was obtained with moderate ee (24% ee), while the syn-addition product 2b was isolated with significant ee (79% ee). Furthermore, we evaluated chiral ligands L7 and L8 and determined that they are less effective for asymmetric induction (entries 3-4). Additionally, chiral ligand L9 induced fast yet non-selective aminochlorination with a high overall yield (entry 5).15 With the iron-L5 complex in hand, we subsequently explored other reaction parameters. First, a decreased reaction temperature was found to benefit both dr and ee (entry 6, dr: 11:1 and 90% ee for 2a at -60 °C). Next, replacing the 3,5-bis(trifluoromethyl) benzoyl activating group with a smaller acetyl group further enhanced the ee (entry 7, 97% ee for 2a); however, much lower dr and yield were obtained (entry 7, dr: 1.1:1, 42% yield). Finally, a chloroacetyl activating group induced an effective balance between overall yield and stereoselectivity (entry 8, 67% yield, dr: 9.6:1 and 89% ee for 2a). We also observed that the FeCl<sub>2</sub>-L5 complex induced a slightly less selective reaction with

In order to evaluate the scope of this asymmetric method, we explored the asymmetric induction with a range of internal olefins (Table 4). The chiral catalyst provides excellent asymmetric induction with styrenyl olefins. A range of parasubstituted styrenyl olefins with different electronic properties were converted to the corresponding aminochlorination products with high dr and ee (entries 1-6, dr: 9.6-15: 1, ee: 86-91%). Additionally, meta-substituted styrenyl olefins are also good substrates but with slightly decreased ee (entries 7-9, dr: 10-15: 1, ee: 80-87%). However, we discovered that ortho-substitution of styrenes has a deleterious effect on ee (entries 10-11, dr: 4.5-12: 1, ee: 77-79%). Interestingly, both  $\alpha$ - and  $\beta$ -naphthyl olefins are excellent substrates (entries 12-13, dr: 4.5-10: 1, ee: 89-92%). To our delight, a 3-pyridyl olefin with a basic nitrogen atom is a reasonable substrate for the asymmetric aminochlorination (entry 14, dr: 1.8:1, ee: 70% for the anti-diastereomer). Moreover, we observed that the iron-L5 complex can induce significant ee in the aminochlorination with non-styrenyl olefins (entry 15, dr. 2:1, ee: 54% for the anti-diastereomer). To our surprise, the iron-L6 complex proved to be uniquely effective for the asymmetric induction with tri-substituted olefins, while the iron-L5 complex was less effective (entry 16, dr: 2.3: 1, ee: 86% for the anti-diastereomer).16

a lower yield (entry 9, 58% yield, dr: 9.0 : 1 and 83% ee for 2a).

<sup>a</sup> Unless stated otherwise, mono-chloroacetyl was selected as the activating group for asymmetric catalysis; the ee for all synaminochlorination products was less than 5%. <sup>b</sup> Bis(trifluoromethyl)-benzoyl was selected as the activating group. <sup>c</sup> The ee for the synaddition product was 12%. <sup>d</sup> L6 was used as the ligand for asymmetric induction; the ee for the syn-addition product was 50%.

During the exploration of substrate scope, it was surprising to observe completely different ee values for anti- and syn-diastereomers (*e.g.* 2a and 2b). In contrast, exactly the same ee for both diastereomeric products was observed in the iron-catalyzed aminofluorination of 1.6 In order to obtain greater mechanistic insights, we carried out ee analysis for all isolable products using several control experiments (Scheme 3). First, in an Fe(NTf<sub>2</sub>)<sub>2</sub>-catalyzed reaction with *trans*-olefin 1, two aminochlorination products were obtained (Scheme 3A, 90% ee for 2a, <5% ee for 2b, dr: 11:1). Simultaneously, diastereomers 5a and 5b were also isolated with the same ee as two competing olefin aminohydroxylation products (Scheme 3A, 88% ee for 5a and 5b, dr: 4:1). However, completely different selectivity (both dr and ee) was observed in an Fe(NTf<sub>2</sub>)<sub>2</sub>-catalyzed reaction with *cis*-olefin 1' (Scheme 3A, 85% ee for 2a and 31% ee for 2b, dr:

A) Fe(NTf)<sub>2</sub>-catalyzed asymmetric aminochlorination and aminohydroxylation with isomeric olefins

C) FeCl<sub>2</sub>-catalyzed and mediated asymmetric olefin aminochlorination reactions

Scheme 3 Control experiments to probe the mechanism. <sup>a</sup>Reaction conditions: Fe(NTf<sub>2</sub>)<sub>2</sub> (15 mol%), L1 (15 mol%), TBAC (2.5 equiv.), CHCl<sub>3</sub>, -60 °C, 12 h. <sup>b</sup>Reaction conditions: Fe(NTf<sub>2</sub>)<sub>2</sub> (15 mol%), L1 (15 mol%), CHCl<sub>3</sub>, -60 °C, 12 h.

6:1; 93% ee for 5a and 83% ee for 5b, dr: 7:1). In both cases, 5a and 5b cannot be converted to 2a under the reaction conditions.

These observations provide several important mechanistic insights. First, the non-stereospecificity observed in the iron-catalyzed olefin aminochlorination suggests that the formation of C–N and C–Cl bonds occurs in a stepwise fashion. Second, the lack of complete stereo-convergence between the reaction profiles of isomeric olefins (1 and 1′) suggests that C–N bond formation may be the rate- and ee-determining step. Furthermore, since essentially the same ee was observed for 2a, 5a, and 5b from the reaction with *trans*-olefin 1, it is likely that these products are derived from the same intermediate after the ee-determining step. Additionally, the fact that the syn-aminochlorination product 2b was isolated as a racemate suggests that 2b may be derived from non-stereoselective pathways

which are distinct from the one leading to the formation of 2a, 5a, and 5b.

The product divergence (2a vs. 5a/b) after the ee-determining step is mechanistically interesting. Therefore, we studied the effect of external chloride ion. To our surprise, in the absence of TBAC, the Fe(NTf<sub>2</sub>)<sub>2</sub>–L5 complex alone was ineffective for the nitrogen atom-transfer at -60 °C; 1 and 1′ were both fully recovered (Scheme 3B). However, aminochlorination occurred as soon as a stoichiometric amount of TBAC was introduced. This observation suggests that the Fe(NTf<sub>2</sub>)<sub>2</sub>–L5 complex may serve as a pre-catalyst and it may be activated by chloride ion *in situ*.

In order to test this hypothesis, we further carried out the FeCl<sub>2</sub>-catalyzed reaction in the presence of TBAC (Scheme 3C). Notably, **2a** was isolated with essentially the same ee as that obtained under the standard conditions (88% ee for **2a** and <5%).

Scheme 4 Proposed mechanistic working hypothesis for the iron-catalyzed asymmetric aminochlorination of trans-olefin 1.

ee for **2b**). This result suggests that the catalytically relevant

ee for **2b**). This result suggests that the catalytically relevant species may also be generated from the FeCl<sub>2</sub>–**L5** complex.

To probe for more mechanistic details, we subsequently carried out the FeCl<sub>2</sub>-promoted olefin aminochlorination in the absence of TBAC (100 mol% FeCl<sub>2</sub>, 100 mol% **L5**, Scheme 3C). Under these conditions, FeCl<sub>2</sub> is the only available chlorine source. Surprisingly, we discovered that **2a** was obtained with essentially the same ee compared with the two previous control experiments (88% ee for **2a**). Furthermore, a syn-aminohydroxylation product **5a** was isolated with excellent dr and ee (dr > 20:1, 88% ee). These observations suggest that Fe–Cl bond cleavage may be relevant for the chlorine atom-transfer step during the enantioselective anti-aminochlorination. In addition, we also identified a small amount of aziridine **6** (15% yield, 82% ee), and further discovered that it could not be converted to either **2a** or **5a** under the reaction conditions.

With the accumulated mechanistic evidence, we propose a plausible mechanistic working hypothesis for the iron-catalyzed asymmetric aminochlorination of *trans*-olefin 1 (Scheme 4). First, the iron catalyst reversibly cleaves the N–O bond in the acyloxyl carbamate 1, generating iron-nitrenoid A with chloride as a counter ion. From there, A may participate in enantioselective and diastereoselective aminochlorination and aminohydroxylation to afford 2a and 5a, respectively. Since the aminochlorination-aminohydroxylation competition occurs after the ee-determining step, 2a is obtained with essentially the same ee as 5a. At the same time, 1 may be converted to 2b *via* a non-stereoselective pathway which is distinct from the one leading to the formation of 2a and 5a. Further mechanistic studies are required to elucidate the details.

#### Conclusions

**Edge Article** 

In conclusion, we have described an iron-catalyzed enantioselective and diastereoselective aminochlorination method for internal, non-chalconic olefins. This method tolerates a range of synthetically valuable olefins that are all incompatible with existing asymmetric olefin aminochlorination methods. It also provides a complementary approach for the asymmetric synthesis of amino chlorides with contiguous stereogenic centers. Our preliminary mechanistic studies revealed that an FeCl<sub>2</sub>-derived nitrenoid may be a feasible reactive intermediate and that Fe–Cl bond cleavage may be relevant for stereoselective chlorine atom-transfer. Our current efforts are focused on the mechanistic investigation of this new reaction and method development for the enantioselective intermolecular olefin aminochlorination.

- 8 See ESI† for details of substrate synthesis. Acyloxyl carbamates are reactive, while tosyloxyl and alkoxyl carbamates are non-reactive and fully recovered under the reaction conditions.
- 9 The relative stereochemistry of 2a was determined by comparison of the experimental NMR data with those reported in ref. 7. It was further corroborated by <sup>1</sup>H NMR and X-ray crystallographic analysis of a structural analog of 2a. See ESI† for details.
- 10 The relative stereochemistry was assigned based on the <sup>1</sup>H NMR and X-ray crystallographic analysis of a structural analog described in ref. 6; see ESI† for details.
- 11 Complementary stereochemistry was achieved (in entry 15 of Table 2) compared with the known method reported in ref. 7, where the syn-aminochlorination product was isolated. This substrate did not undergo kinetic resolution with a

- chiral catalyst, the complex Fe(NTf<sub>2</sub>)<sub>2</sub>-L5. Both the starting material and product were isolated as racemates.
- 12 For leading references on chiral BOX and related ligands, see: (a) D. A. Evans, K. A. Woerpel, M. M. Hinman and M. M. Faul, J. Am. Chem. Soc., 1991, 113, 726; (b) H. Nishiyama, Y. Itoh, H. Matsumoto, S.-B. Park and K. Itoh, J. Am. Chem. Soc., 1994, 116, 2223; (c) Y. Nishikawa and H. Yamamoto, J. Am. Chem. Soc., 2011, 133, 8432.
- 13 The absolute stereochemistry of 2a was determined by X-ray crystallographic analysis of a structural analog of 2a. See ESI† for details.
- 14 For detailed procedure and HPLC traces of 4, see ESI.†
- 15 For the synthesis of L9, see ref. 6.
- 16 The iron-L5 complex catalyzed the reaction favoring the synaddition product (dr (anti/syn): 0.47:1); ee for the antiaddition product was 60% and ee for the syn-addition product was <5%. The relative stereochemistry was assigned based on the <sup>1</sup>H NMR and X-ray crystallographic analysis of a structural analog described in ref. 6; see ESI† for details.
- When a chloroacetyl group was used as the activating group, a different result was obtained. For details, see entry 8 of Table 3.
- 18 For an example of stepwise atom transfer reactions with different reaction profiles for cis/trans isomeric olefins, see: N. H. Lee and E. N. Jacobsen, Tetrahedron Lett., 1991, 32, 6533.
- 19 For the oxidation of a radical species by a high-valent metal through ligand transfer or electron transfer, see: (a) M. S. Kharasch and G. Sosnovsky, J. Am. Chem. Soc., 1958, **80**, 756; (b) J. K. Kochi, Science, 1967, **155**, 415. For a relevant enzymatic C-H chlorination reaction hydrocarbons catalyzed by iron-containing metalloenzymes, see: (c) F. H. Vaillancourt, J. Yin and C. T. Walsh, Proc. Natl. Acad. Sci. U. S. A., 2005, 102, 10111.
