## Transition-metal-catalyzed auxiliary-assisted C–H functionalization using vinylcyclopropanes and cyclopropanols

Shubhajit Basak,  Tripti Paul,  Santu Mandal,  Madhab Barman, Maniya V Nanjgowda  and Tharmalingam Punniyamurthy \*

Transition-metal-catalyzed chelation-assisted C–H functionalization exploiting small strained rings has surfaced as an appealing strategy, offering a robust platform for the construction of complex molecules in a step- and atom-economic fashion. In this vein, three-membered rings, viz. vinylcyclopropanes (VCPs) and cyclopropanols, have emerged as staple coupling partners due to their inherent ring strain. Moreover, their strain release serves as a potent driving force, unlocking new possibilities in molecular engineering via sequential C–H functionalization and ring scission. Recently, significant progress has been made in this emerging domain employing the aforementioned rings. This review article focuses on directing group (DG)-assisted C–H functionalization adopting VCPs and cyclopropanols as potential coupling partners until November 2024. The advancements are organized based on the type of functionalizations achieved.

### 1. Introduction

The emergence of DG-assisted C–H functionalization utilizing transition-metal (TM) catalysis has garnered significant attention due to the rapid construction of C–C/C–heteroatom bonds in a predictable way.<sup>1</sup> Moreover, the omnipresence of C–C bonds as pivotal structural constituents in organic molecules underscores the importance of their formation and cleavage in synthetic chemistry.<sup>2</sup> In this paradigm, selective C–C cleavage

has led to a leading-edge synthetic method for the construction of structurally complex organic molecules. However, the lack of bond polarization and high bond strength make C–C activation a formidable challenge. Along this line, tremendous efforts have thus been devoted to enabling TM-catalyzed selective C–C bond cleavage.<sup>3</sup> A useful approach involves the employment of strained small-ring systems as versatile synthons.<sup>4</sup> The strain-release energy associated with their cleavage serves as a substantial driving force, rendering them ideal scaffolds for TM-catalyzed C–C activation. In particular, three or four-membered rings manifest as a suitable candidate as the thermodynamic barrier for C–C bond scission is compensated by their inherent strain

Fig. 1 Reactivity profile of VCP and cyclopropanol with C–H substrates under TM-catalysis.

(Fig. 1A). Belonging to the class of three-membered rings, VCPs and cyclopropanols can function as versatile building blocks for the synthetic elaboration of organic scaffolds.<sup>5</sup> In addition, the facile ring opening of VCP may involve  $\beta$ -carbon elimination to

execute C–C bond cleavage, whereas ring-opening of cyclopropanol forms an organometallic  $\gamma$ -oxo alkyl-metal intermediate, leading to C–C bond formation (Fig. 1B).

Furthermore, due to the enhanced reactivity of small rings, they are susceptible to rapid decomposition, homocoupling or attack by available nucleophiles. Consequently, the prudent choice of TM-catalysts and appropriate C–H substrates is crucial for an impactful transformation. In this context, an assortment of TM-catalysts and substrates tailored with DGs are adopted for harnessing the reactivity of these rings. In addition, the installation of DGs or pre-existing directing functionality in a substrate is paramount to define the reaction pathway, offering advanced regiocontrol. Frequently implemented DGs include *N*-containing functionalities due to their strong chelating ability and the formation of thermodynamically stable cyclometalated intermediates. However, recent years have witnessed tremendous attention to the utilization of weak-chelating DGs,<sup>6</sup> resulting in a less stable metallacycle, thus increasing the propensity to react with the strained rings. From this viewpoint, the compatibility among DG-tethered substrates, ring systems and metal-catalysts requires a comprehensive assessment.

In pursuit of addressing the persistent synthetic obstacle, the integration of C–H functionalization and C–C cleavage in a

Tharmalingam Punniyamurthy is Professor of Organic Chemistry at the Indian Institute of Technology Guwahati. His research interests include the site-selective C–H functionalization and expansion of strained ring systems for the construction of heterocyclic scaffolds. He is a fellow of the Indian Academy of Sciences, the National Academy of Sciences, India, the Indian National Science Academy and the Royal Society of Chemistry, and a recipient of a CRSI Silver Medal and J C Bose National Fellowship.

Fig. 2 General outline of C-H functionalizations with VCPs and cyclopropanols.

unified tandem process employing strained rings furnishes a potential approach to access complex molecular architectures.<sup>7</sup> From this perspective, the catalytic ring scission of VCPs and cyclopropanols for DG-assisted C-H functionalization has gained considerable interest. Alongside, the seminal studies by the research groups of Ackermann, Glorius, Gooßen, Li, Shi and many others have occupied a prominent position in the archives of synthetic chemistry. Recently, our group has made a significant contribution to this emerging area utilizing the aforementioned moieties. Given the importance and surge in demand, a current update on directed C-H functionalization exploiting the ring cleavage of VCPs and cyclopropanols would thus be valuable. This article attempts to collate the chronological developments in TM-catalyzed chelation-assisted C-H functionalization with VCPs and cyclopropanols until November 2024. The advances presented are categorized based on the types of transformations, such as allylation, alkenylation, alkylation and annulation (Fig. 2). The reactivity pattern of the associated subunits, key mechanistic underpinnings and important synthetic diversifications in a few instances are addressed. However, the Lewis acid-catalyzed ring opening or cycloaddition reactions of these are well documented,<sup>5</sup> and hence not covered here.

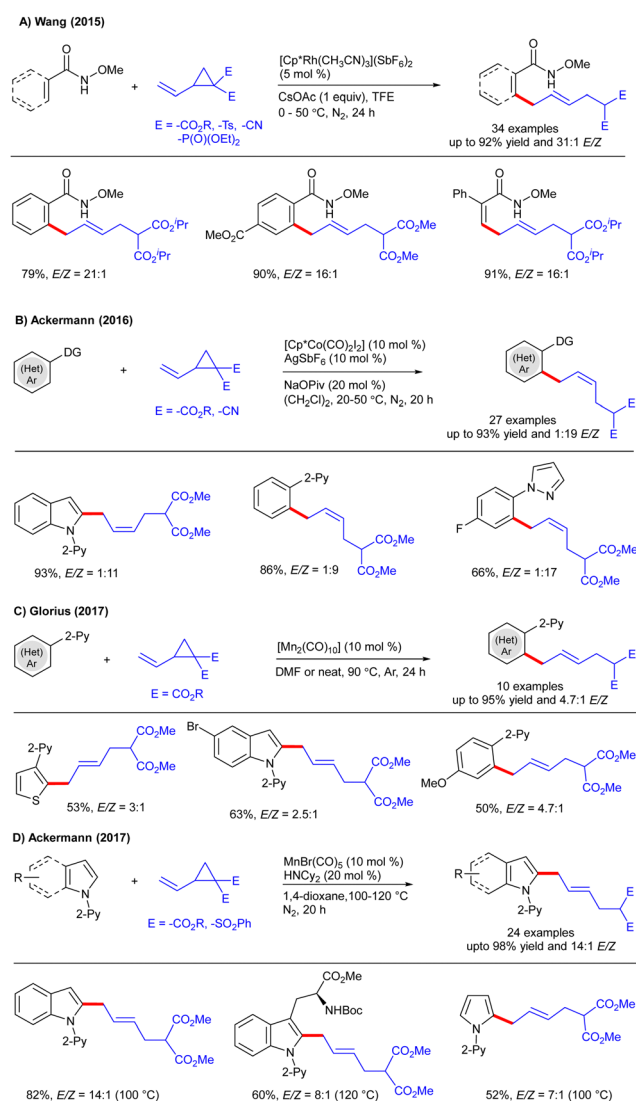

## 2. Reactions using vinylcyclopropanes

Readily accessible VCP, due to its tailor-made nature with a strained cyclopropane ring and a conjugated vinyl group, has garnered tremendous attention in organic synthesis.<sup>5c-e</sup> The inherent ring strain ( $\sim 28$  kcal mol<sup>-1</sup>) makes it highly susceptible to ring opening *via* C-C bond cleavage mediated by Lewis acids, radical pathways and TM-catalysis.<sup>5g</sup> From the perspective of step- and atom-economy, TM-catalyzed tandem C-H/C-C functionalization offers a highly efficient strategy to access diverse scaffolds with significant applications in medicinal and material science.<sup>7</sup> In this context, VCP serves as a promising coupling partner facilitating the synthesis of allyl surrogates or carbocyclic scaffolds that are challenging to produce through conventional methods. This section explores the advancements achieved through C-H functionalization utilizing VCPs.

### 2.1. Allylation

The significance of allylated derivatives in natural products and medicinal compounds has made the allylation strategy a key area of scholarly interest. Alkenes are widely utilized as

coupling partners in TM-catalyzed C-H allylation.<sup>8</sup> Recently, direct allylation through the synergistic activation of C-H and C-C bonds in a single step has gained significant attention, employing VCPs as a coupling partner. In 2015, Wang and co-workers realized a Rh(III)-catalyzed C-H allylation of *N*-methoxy benzamides using VCPs (Scheme 1A).<sup>9</sup> The reaction exhibits good compatibility with aliphatic alkenyl C-H functionalization and the sterically bulky substituents of the ester group of VCP gave better *E/Z*-selectivity. Subsequently, an elegant approach was demonstrated by the Ackermann group utilizing cost-effective Co(III)-catalysis for strong chelation-assisted indole and arene C-H allylation with VCPs (Scheme 1B).<sup>10</sup> The reaction selectively yielded the thermodynamically less stable *Z*-alkenes under mild reaction conditions. The origin of the *Z*-selectivity using Co-catalysis has been supported by the DFT studies, which implied that the key C-C cleavage of VCP is the diastereoselectivity-determining step, whose energetic span is less for the formation of the *Z*-diastereomer compared to that of the *E*-diastereomer.

Scheme 1 Metal-catalyzed C-H allylation of (hetero)arenes with VCPs.

Scheme 2 C7-allylation of indolines under Rh(III)-catalysis.

This might be attributed to shorter Co–C bonds, leading to more compact organometallic species. Notably, the sterically hindered pivalate additive was essential for the reaction.

Later, the Glorius group reported the economically viable Mn(I)-catalyzed 2-pyridyl-directed C–H allylation of (hetero)arenes using VCPs with excellent *E/Z*-selectivities (Scheme 1C).<sup>11</sup> Interestingly, the methodology showed remarkable efficiency under silver and solvent free conditions, exhibiting excellent functional group tolerance. At the same time, the Ackermann group accomplished 2-pyridyl-assisted *E*-selective C–H allylation of (hetero)arenes with VCPs utilizing MnBr(CO)<sub>5</sub> as the catalyst (Scheme 1D).<sup>12</sup> The DFT study revealed that London dispersion interactions play a significant role in stabilizing the (*E*)-transition-state. Moreover, the allylation strategy was well suited for the late-stage modification of amino-acids. Furthermore, Zhu and Song groups reported a Rh(III)-catalyzed C7–H allylation of indolines with VCPs (Scheme 2).<sup>13</sup> A wide range of substrates were amenable to provide the allylated products in high yields with good functional group compatibility.

Scheme 3 Metal-catalyzed *ortho*-allylation of (hetero)arenes.

In 2019, Gooßen and co-workers developed the Ru-catalyzed *ortho*-C–H allylation of aromatic acids with VCPs (Scheme 3A).<sup>14</sup> A broad spectrum of allylarenes was synthesized in high yields and stereoselectivities. In addition, the allylation can be combined with follow-up steps to enable the synthesis of functionalized coumarins. In the same year, Yoshino and Matsunaga demonstrated the Co-catalyzed C–H allylation of NH-free benzimidates using VCPs under mild reaction conditions (Scheme 3B).<sup>15</sup> The key features include *Z*-selective C–H allylation with an unaltered imidate group, which enables a second C–H functionalization and cyclization, leading to important heterocycles. Later, the Song and Zhu groups updated the allylation strategy enhancing its synthetic value with a focus on green and sustainable principles. This work featured a solvent-free microwave-assisted direct C7-allylation of indolines with VCPs at room temperature (Scheme 4A).<sup>16</sup> A wide range of substrates were tolerated to afford the allylated indolines in high yields and *E/Z*-selectivities. The scope of the procedure was extended for the allylation of tetrahydroisoquinolines. Meanwhile, the same group reported bisallylation using imidazopyridines as intrinsic DGs with VCPs (Scheme 4B).<sup>17</sup> The reaction proceeds with a five-membered ruthenacycle, which furnished a mono-allylated metal complex *via* C–H/C–C functionalization with one molecule of VCP. The mono-allylated intermediate undergoes a 2<sup>nd</sup> C–H functionalization through a rollover mechanism, leading to bis-allylation with another molecule of VCP.

Scheme 4 (A) Microwave-assisted CH-allylation of indolines and tetrahydroisoquinolines. (B) Bis-allylation strategy under Ru(II)-catalysis.

In the ensuing year, the Shi group described an enantioselective synthesis of axially chiral biaryls with VCPs under Pd(II)-catalysis (Scheme 5).<sup>18</sup> The ligand acts as a transient DG, governing the stereochemistry of the product by making an enantioenriched palladacycle **A** via C–H activation. The coordination and insertion of VCP gives **B** that undergoes C–C cleavage and protonolysis to produce the allylation product **C**. The latter was subjected to RANEY<sup>®</sup>-Ni/H<sub>2</sub> reduction to give the desired product in moderate to high yields. The synthetic utility was shown by gram-scale synthesis and further synthetic transformations to access various axially chiral biaryls with up to >99% ee. Soon after, the Zhang and Shi groups documented the Co(III)-catalyzed C–H allylation of ferrocenes with VCPs using thioamide as the DG (Scheme 6).<sup>19</sup> The reaction showed good Z-selectivity when stirred with 10 mol % of [Cp\*Co(CO)I<sub>2</sub>] and 20 mol % of AgSbF<sub>6</sub> in CH<sub>2</sub>Cl<sub>2</sub> at 100 °C for 24 h. The Z-selectivity might be due to the geometric orientation of the intermediate during the key C–C cleavage of VCP under Co-catalysis.<sup>10</sup>

Later, Li and co-workers developed a switchable C- and N-allylation with chemo- and site-selectivities using *N*-nitroso anilines (Scheme 7A).<sup>20</sup> The C–H allylation was compatible with a diverse array of substrates under Rh(III)-catalysis. Furthermore, the Kapur group demonstrated an allylation under Ru-catalysis to afford anilines with excellent *E/Z*-selectivities (Scheme 7B).<sup>21</sup> Most of the

Scheme 7 Directed *ortho*-C–H-allylation of arenes.

anilines and VCPs responded well with good functional group tolerance. The authors noted that Cu(OAc)<sub>2</sub>·H<sub>2</sub>O and Cs<sub>2</sub>CO<sub>3</sub> were crucial, as their absence led to significantly lower yields.

Recently, our group developed distal C8–H allylation of quinoline *N*-oxides using VCPs under Rh(III)-catalysis at ambient temperature (Scheme 8).<sup>22</sup> The reaction features broad

Scheme 5 Pd(II)-catalyzed enantioselective functionalization of biaryls.

Scheme 6 Co(III)-catalyzed C–H-allylation of ferrocene.

Scheme 8 C8–H allylation of quinolines using an *N*-oxide DG.

substrate scope with excellent *E/Z*-selectivities. In this reaction,  $[\text{Cp}^*\text{RhCl}_2]_2$  with  $\text{AgBF}_4$  and  $\text{NaOPiv}$  generates active  $\text{Rh}(\text{III})$ -species **A**, which activates the C8–H bond of the substrate and produces **B**. Co-ordination and migratory insertion of VCP resulted in a seven-membered metallacycle **D**. Energetically favoured  $\beta$ -carbon elimination *via* C–C bond cleavage and protodemetalation yielded the target product.  $\text{Ag}(\text{I})$  oxidizes  $\text{Rh}(\text{I})$  species **F** to regenerate the active  $\text{Rh}(\text{III})$ -species and complete the catalytic cycle. In continuation of our previous interest and due to the prevalence of allyl arenes in numerous natural products and pharmaceuticals, we reported sulfoxonium ylide-directed  $\text{Co}(\text{III})$ -catalyzed C–H allylation of (hetero)arenes (Scheme 9).<sup>23</sup> In the post-synthetic modifications, sulfoxonium ylide DG was seamlessly converted into various derivatives as illustrated. Furthermore, the ubiquity of the allylated indole moiety in numerous drug molecules motivated the development of an efficient methodology for weak chelation-assisted distal C4–H allylation of indoles under redox-neutral ruthenium(II) catalysis, using VCPs (Scheme 10).<sup>24</sup> The reaction proceeds with active  $[\text{Ru}]$ -complex **A**, which eventually activates the C4–H bond of the indole substrate to produce the ruthenacycle **B**. Co-ordination of VCP followed by 1,2-migratory insertion may lead to the formation of **D**. Chelation with the ester functionality assists  $\beta$ -carbon elimination to furnish **E**. Finally, protodemetalation leads to product formation and regenerates the active catalyst **A**. The regioselectivity, substrate scope and *E/Z*-selectivities are the key features. Moreover, the procedure was extended to benzothiophene, tetrahydroquinoline, carbazole,  $\alpha$ -tetralone and indoline moieties for selective allylation.

Later, the Baidya group reported an amine directed *ortho*-C–H functionalization of 2-aminobiaryls with VCPs under high-valent Co-catalysis, enabling regio- and stereo-selective allylation (Scheme 11).<sup>25</sup> The innate nucleophilic reactivity of an amine group makes their use as a DG synthetically challenging. The authors have shown the mechanistic experiments and DFT calculations to unravel the reaction pathway. Initially, the  $\text{Co}(\text{III})$  species **A** undergoes *ortho*-C–H activation with aniline *via* BIES

Scheme 10 Redox-neutral acyl DG-assisted C4–H allylation of indoles.

(base-assisted internal electrophilic type substitution) to afford the four-membered cobaltacycle **B**. Chelation with VCP affords **C**, which undergoes migratory insertion to provide **D**. The C–C cleavage of **D** gives **E** that undergoes protodemetalation to give the allylation product and the active catalyst **A** to complete the catalytic cycle. The late-stage modifications of the products lead to valuable benzoisoxazoles and dihydrophenanthridines. Recently, the Jeganmohan group demonstrated the palladium-catalyzed regioselective allylation of unactivated alkenes with VCPs (Scheme 12).<sup>26</sup> The reaction aided by weak-coordinating native amide DG was well tolerated over a broad range of substrates with excellent  $\beta$ -selectivity. In addition, secondary amides are proved to be more reactive than primary amides. In contrast to conventional VCP allylation, the mechanism differs significantly as explained by the authors. First, the  $\text{Pd}(\text{0})$ -complex **A** with  $(\text{EtO})_2\text{MeSiH}$  generates **B** that undergoes elimination of  $(\text{OEt})_2\text{MeSi}(\text{OAc})$  using  $\text{AcOH}$  to yield the cationic  $(\text{N,N})\text{Pd-H}$  species **C**. Chelation of the amide gives **D** that leads to hydride transfer to furnish **E**, which undergoes  $\beta$ -hydride elimination to afford the isomerized alkene **F**. Hydride transfer produces the palladacycle **G**, which leads to chelation with VCP to yield  $\eta^1$ -palladium species **I**. Reductive elimination provides the target product and the  $\text{Pd}(\text{0})$ -complex to complete the catalytic cycle. Regioselectivity in direct C(alkenyl)–H functionalization remains challenging due to the presence of

Scheme 9 Sulfoxonium ylide directed *ortho*-C–H allylation.

**Scheme 14** Synthesis of C2-substituted indoles *via* annulative coupling with VCPs.

as a by-product. The protocol shows excellent compatibility with various functional groups and late-stage derivatization of commercial drugs. The proposed mechanism begins with reversible C-H activation to generate rhodacycle **A**, double bond chelation of VCP followed by migratory insertion into the Rh-C bond generates **B**. The latter undergoes rearrangement to form **C**, which evolves into a Rh  $\alpha$ -oxo carbene **D** with the liberation of DMSO. The  $\beta$ -carbon elimination of **D** leads to **E** that undergoes intramolecular cyclopropanation to yield fused **F** (path a), which upon protodemetalation delivers the target product. An alternative pathway (path b) involves reductive migratory insertion forming **G**, followed by nucleophilic attack of the  $\alpha$ -carbon to the proximal carbon, giving the target product. Furthermore, our group reported ligand-promoted Pd(n)-catalyzed C(sp<sup>3</sup>)-H/C-C functionalization of

**Scheme 15** Rh-catalyzed sulfoxonium-ylide directed C-H/C-C functionalization with VCPs.

**Scheme 16** Pd-catalyzed sulfonamide directed C(sp<sup>3</sup>)-H/C-C functionalization with VCPs.

aliphatic amides with VCPs to produce functionalized  $\gamma$ -lactams (Scheme 16).<sup>31</sup> VCP displayed unusual reactivity, favouring alkenylation followed by cyclization instead of the formation of the open chain allyl product. The protocol showcased a wide substrate scope with exclusive (*E*)-selectivity and post-synthetic utilities. Notably, monodentate sulfonyl-based protecting groups (Ns, Mbs, Bs) proved effective, while bidentate DGs failed to give the desired outcome. Alkyl pyridine (**L**) promotes the catalytic activity through coordination with palladium, which activates the  $\beta$ -C(sp<sup>3</sup>)-H bond leading to the formation of five-membered palladium intermediate **A**. Alkene coordination, followed by migratory insertion generates **B**, which undergoes  $\beta$ -hydride and reductive elimination to give intermediate **D**. The latter undergoes aminopalladation and C-C cleavage of cyclopropane, giving rise to **G** that leads to protodemetalation to afford the target product.

### 3. Reactions using cyclopropanols

The constrained cyclic framework cyclopropanol, which can be readily synthesized *via* Kulinkovich or Simmons-Smith

cyclopropanation, is an adaptable three-carbon synthon in synthetic chemist's toolbox due to its strain energy and primed reactivity.<sup>5a,b</sup> Cyclopropanol generates metal-homoenolates or  $\beta$ -keto alkyl radicals under TM-catalysis, enabling it to act as either a nucleophile or an electrophile, depending on the reaction context.<sup>5f</sup> This remarkable versatility renders cyclopropanol a unique and indispensable resource in modern organic synthesis. Although numerous strategies involving cyclopropanol have been developed, the integration of C–H functionalization with the ring-opening of cyclopropanol remains a burgeoning area of research. Moreover, the single-step incorporation of a three-carbon unit is often essential for the diversification of biologically potent molecules. This section delves into the specific outcomes of C–H functionalization with cyclopropanols.

### 3.1. Alkylation

TM-catalyzed site-selective C–H alkylation with cyclopropanols set out a way upfront to complex organic molecule synthesis, because it introduces a  $\beta$ -keto alkyl/aryl group that can act as an effective synthetic handle for further useful manipulation. In 2016, Li and co-workers employed cyclopropanols in the Rh-catalyzed oxidative alkylation of arenes *via* tandem C–H/C–C functionalization (Scheme 17A).<sup>32</sup> Both oxime ether and 2-pyrimidyl served as effective DGs for the alkylation providing the products with exclusive site-selectivity. This methodology was further applied for C(sp<sup>3</sup>)–H alkylation of 8-methyl quinoline affording the  $\gamma$ -aryl

Scheme 17 Rh-catalyzed coupling of (hetero)arenes with cyclopropanols.

Scheme 18 Pd-catalyzed atroposelective C–H/C–C functionalization with cyclopropanols.

ketones. Concurrently, the authors came up with 2-pyrimidyl DG assisted regioselective alkylation of (hetero)arenes using cyclopropanols (Scheme 17B).<sup>33</sup> A wide variety of heteroarenes, including indolines, carbazoles, thiophene and pyrroles were effective substrates, providing significant yields of the alkylated products.

Later, a site-selective alkylation of 2-arylquinazolin-4(3H)-one was reported by Peng and co-workers (Scheme 17C).<sup>34</sup> This methodology was amenable to a variety of functional groups like alkyl, alkoxy and halogen as well as heteroarenes. However, electron withdrawing substituents on the arylquinazolin-4(3H)-ones provided lower yield. Soon after, an elegant work in this area was disclosed by Shi and co-workers (Scheme 18).<sup>18</sup> They used cyclopropanols for the synthesis of axially chiral biaryls *via* enantioselective tandem C–H/C–C functionalization. The authors suggested that due to the competitive  $\beta$ -hydride elimination and protodemetalation under Pd-catalysis, both alkylation and alkenylation were observed. The key to the success of the procedure was represented by the access of a broad range of axially chiral biaryls in synthetically convenient yields and high enantiopurity. In the same year, the Liu and Liu groups developed the Rh-catalyzed oxidative alkylation of *N*-aryl-7-azaindoles with regioselectivity and functional group compatibility (Scheme 19).<sup>35</sup> In addition, the method proved its potential applicability by transforming the  $\beta$ -aryl ketones into 7-azaindole containing  $\pi$ -extended poly-heterocycles.

Recently, we accomplished a weak acyl chelation-guided indole C4–H alkylation with cyclopropanols utilizing Rh-catalysis (Scheme 20).<sup>36</sup> A wide range of substituted indoles and cyclopropanols were evaluated to check the practicality.

Scheme 19 Rh-catalyzed alkylation of *N*-aryl-7-azaindoles with cyclopropanols.

**Scheme 20** Rh-catalyzed C4-selective alkylation of indoles with cyclopropanols.

The procedure showed potential amenability to other carbonyl DG-tethered (hetero)aryl substrates, *e.g.* benzo[*b*]thiophene, indoline and tetrahydroquinoline. To shed light on the reaction pathway, H/D-scrambling experiments were conducted either in the presence or absence of cyclopropanol, which resulted in 12% and 27% deuterium incorporation at the C4-site, respectively. Based on the detailed mechanistic studies, a plausible catalytic cycle was depicted, in which the active Rh-catalyst **A** activates the C4-H bond to furnish rhodacycle **B**, which undergoes ligand exchange with cyclopropanol to give **C**. Subsequent  $\beta$ -carbon and  $\beta$ -hydride elimination leads to the formation of **E**, which undergoes aryl insertion into the double bond, furnishing eight-membered rhodacycle **F**. The latter upon protodemetalation produces the alkylated product and Rh(I)-species, which is oxidized to the active catalyst **A** by Cu(II), completing the catalytic cycle. Furthermore, the Anbarasan group reported the Rh-catalyzed C2-H alkylation of indole with cyclopropanols using an *N,N*-

**Scheme 21** Metal-catalyzed regioselective alkylation with cyclopropanols.

dialkylcarbamoyl group as the traceless DG (Scheme 21A).<sup>37</sup> Moreover, pyrrolo[1,2-*a*]indole can be obtained from the alkylated product through a reduction followed by cyclization. Concurrently, they utilized Co-catalysis for the C2-H alkylation of *N*-pyridylindoles *via* the ring scission of cyclopropanols (Scheme 21A).<sup>38</sup> The use of AgSbF<sub>6</sub> and Cu(OAc)<sub>2</sub>·H<sub>2</sub>O is essential, as they play a key role in synthesizing active catalysts for C-H functionalization. The ketone functionality in the alkyl moiety facilitates the formation of tetrahydrocyclopenta-*[b]*-indole and C2-allylated indole, reflecting the synthetic versatility of the procedure. Later, the authors showed the Rh-catalyzed *ortho*-alkylation of *N*-(hetero)aryl pyrazoles with cyclopropanols (Scheme 21B).<sup>39</sup> This method enables nonsymmetrical dialkylation, showcasing the practicality of the strategy.

Our group exploited cyclopropanols for the Co-catalyzed C8-H alkylation of quinolines using *N*-oxide as a weak chelating DG

**Scheme 22** Co-catalyzed C8-selective alkylation of quinolines with cyclopropanols.

Scheme 23 Ru- and Rh-catalyzed alkylation with cyclopropanols.

(Scheme 22).<sup>40</sup> This protocol was suited for a wide range of quinolines and cyclopropanols to afford the alkylated products.

Moreover, the potent synthetic ability of the method was exemplified by late-stage modification of natural products and drug molecules. The directing auxiliary could easily be removed by the treatment of  $\text{PhB(OH)}_2$ . Furthermore, when the target product was treated with  $\text{TMSCN}$ , a C2-cyanated quinoline derivative was realized. In the same year, the Ru-catalyzed, Cu-mediated C(3)/C(4)-alkylation of *N*-pyridylisoquinolones was detailed by the Kapur group (Scheme 23A).<sup>41</sup> Electron withdrawing groups facilitated the C3-alkylation, while electron donating ones eased C4-alkylated product formation. A detailed mechanistic study along with DFT studies revealed the co-existence of the intermediates, such as homoenolate and  $\beta$ -keto alkyl radical species, which are implicated in the formation of C3- and C4-products, respectively. Furthermore, Volla and co-workers illustrated Rh-catalyzed aldehydic and aryl C–H alkylation with cyclopropanols (Scheme 23B).<sup>42</sup> The utility of the method was highlighted by post-synthetic transformation of the products into valuable heterocycles, including pyrrole, pyridazine and indole derivatives.

### 3.2. Alkenylation

C–H alkenylation utilizing TM-catalysis has attracted immense attention in recent times because of the ability for efficient downstream transformations. In this context, the Hurski group reported Pd-catalyzed removable 2-(neopentylsulfinyl)-aniline assisted arene C–H alkenylation using cyclopropanol as a vinyl ketone surrogate (Scheme 24).<sup>43</sup> This methodology was compatible with various functional groups, such as alcohol and nitroaromatics.

More recently, our group accomplished biorelevant intrinsic DG-assisted arene C–H alkenylation with cyclopropanol under

Scheme 24 Pd-catalyzed C–H alkenylation of arylacetamides with cyclopropanols.

Ru-catalysis (Scheme 25).<sup>44</sup> A diverse array of  $\alpha,\beta$ -unsaturated ketone functionalities were successfully introduced using DGs like  $\beta$ -,  $\gamma$ - and  $\epsilon$ -lactams, isoindolinone, pyridone and morpholinone. Scale-up synthesis and divergent transformations from the alkenylated product demonstrated its profound synthetic potential. A mechanistic blueprint was proposed, where the reaction commenced with the formation of an active Ru-catalyst **A**, followed by reversible C–H activation leading to the formation of six-membered ruthenacycle **B**. Ligand exchange with cyclopropanol and  $\beta$ -carbon elimination gives **D**. Furthermore,  $\beta$ -hydride elimination and aryl insertion into the double bond of **E** affords **F** that undergoes  $\beta$ -hydride elimination to furnish the target product and Ru(0)-species, which is oxidized by Cu(II) to regenerate the active catalyst.

Scheme 25 Ru-catalyzed arene C–H alkenylation with cyclopropanols.

## 3.3. Annulation

C–H functionalization/annulation under TM-catalysis offers a powerful and modular approach for constructing decorated heterocycles that are omnipresent in natural products and pharmaceuticals. In this regard, cyclopropanol has emerged as an effective and prominent coupling partner. In 2017, the Li group disclosed the Rh(III)-catalyzed annulation of imidamides with cyclopropanols for the construction of 2-substituted quinoline heterocycles (Scheme 26A).<sup>45</sup> Interestingly, cyclopropanol served as the C3-synthon in annulation and afforded ample substrate scope *via* sequential C–H/C–C functionalization and C–C/C–N bond formation. The role of Cu(OAc)<sub>2</sub> as an oxidant is crucial for annulation, while Fe(III) salt facilitates electron transfer during the oxidation process. Later, the Liu and Liu groups reported the synthesis of C3-substituted isoindolinones *via* the Rh(III)-catalyzed cyclization of oxazolines (Scheme 26B).<sup>46</sup> The bifunctional nucleophilic oxazoline-directed cyclization entailed the cleavage of three chemical bonds and allowed the formation of C–C, C–N and C–O bonds in a single step. Of note, the ring opening of oxazolines *via* nucleophilic attack by acetate enabled an efficient route to synthesize substituted isoindolin-1-ones. An array of oxazolines and cyclopropanols reacted smoothly, but the reaction conditions were ineffective for relatively bulky 1,2-disubstituted

cyclopropanols as well as less strained cyclobutanol and cyclopentanol. Mechanistically, the catalytic cycle begins with the active catalyst **A**, which undergoes oxazolonyl-assisted C–H bond activation to afford five membered rhodacycle **B**. Migratory insertion of the *in situ* formed enone into an aryl–Rh bond afforded **C** that undergoes β-hydride elimination to furnish **D** together with a Rh(I) species. Intramolecular aza-Michael addition of **D** forms oxazolinium salt **E**, which upon attack by acetate furnishes the product and the active catalyst is regenerated using a Cu(II) oxidant. In addition, the Yu group reported the fabrication of isoindolin-1-ones *via* C–H/N–H functionalization and [4+1] annulation of *N*-(quinolin-8-yl)benzamide with cyclopropanols under Co(II)-catalysis (Scheme 27A).<sup>47</sup> The method offers utilization of the earth-abundant Co(OAc)<sub>2</sub>·H<sub>2</sub>O as the catalyst along with Ag<sub>2</sub>CO<sub>3</sub> and TEMPO as the oxidants. Among various DGs screened, 8-aminoquinoline was superior to other *N,N*- and *N,O*-bidentate chelations. Meanwhile, the Huang and Yang groups showed the Rh-catalyzed C–H/C–C functionalization/cyclization of carboxylic acid with cyclopropanols to afford 3-substituted phthalides and α,β-butenolides (Scheme 27B).<sup>48</sup> Remarkably, this catalytic method displays the synthesis of bioactive compounds bearing 3-substituted phthalide scaffolds. Later, the Guan and Wu groups disclosed a coupling of benzamides with cyclopropanols under Ir(III)-catalysis using KOAc as an additive (Scheme 27C).<sup>49</sup>

Scheme 26 Rh-catalyzed annulative coupling with cyclopropanols.

Scheme 27 Metal-catalyzed C–H functionalization/annulation with cyclopropanols.

Scheme 28 Rh-catalyzed cascade annulation *via* C–H/C–C functionalization.

Solvent screening revealed that the protic solvents such as MeOH were the optimal choice due to their better solubility for KOAc compared to aprotic solvents. The reaction showcased broad substrate scope *via* C–H functionalization and annulation, where cyclopropanol served as a one-carbon partner for intermolecular annulation. In 2022, the Liu and Liu groups introduced a three-component synthetic strategy to access structurally diverse benzofuran-3(2*H*)-ones *via* sequential C–H/C–C functionalization and annulation of salicylaldehyde, cyclopropanol and alcohols under Rh(III)-catalysis (Scheme 28A).<sup>50</sup> The choice of solvent, such as MeOH, was vital. In addition, control experiments suggest that the *ortho*-hydroxy group plays a pivotal role for initial aldehyde C–H bond functionalization. Recently, the Ling, Chen and Yao groups described the Rh-catalyzed cyclization of substituted pyrazoles with cyclopropanols to form pyrazolo[5,1-*a*]isoindoles (Scheme 28B).<sup>51</sup> A variety of substituted pyrazoles and cyclopropanols were coupled smoothly. Moreover, the protocol enables late-stage functionalization of biologically important compounds. In 2024, the Zhang and Fan groups reported the synthesis of indane fused bicyclic pyrazolidinones through a one-pot reaction of aryl azomethine imines with cyclopropanols under Rh-catalysis (Scheme 28C).<sup>52</sup> The reaction was well tolerated with phenyl azomethine imines and cyclopropanols. Mechanistically, the reaction proceeds *via* C–H/C–C functionalization, where cyclopropanol showed multiple roles by acting as an alkylating agent as well

as a masked nucleophile and electrophile for the fabrication of both indanes and bicyclic pyrazolidinones.

## 4. Conclusion and outlook

Over the preceding decades, directed C–H functionalization under TM-catalysis has evolved into a linchpin strategy for enhancing molecular intricacy. Recently, in view of step-/atom-economy, sequential C–H and C–C functionalization continues to expand the synthetic toolkit for constructing C–C and C–heteroatom bonds. Towards this goal, small ring systems (three- or four-membered) can serve as a cornerstone due to their high reactivity pertaining to strain relief. Being a congener within the three-membered carbocycles, VCPs and cyclopropanols are proven to be promising synthetic precursors that can undergo C–C cleavage *en route* to important molecular frameworks. A breakthrough has been achieved in the chelation-assisted concomitant C–H and C–C functionalization implementing both the mentioned rings. This article aims to cover the recent findings, including our contributions to DG guided C–H functionalization employing VCPs and cyclopropanols to date. Despite the commendable progress, there is still a synthetic void that requires improvement by introducing either a precisely DG-tailored substrate or efficient and economically viable catalytic system. In this scenario, the traceless/transient DG- or template-assisted strategies would be instrumental in achieving proximal or distal C–H functionalization with the aforementioned rings. Furthermore, the more inert C(sp<sup>3</sup>)-H functionalization leveraging VCPs and cyclopropanols in the presence of effective chiral ligands could contribute to the exploration of enantioselective transformations. In addition, the utilization of more abundant metal catalysts in combination with electro- and photo-catalysis may exhibit excellent potential for fostering practical and sustainable developments in this direction. We anticipate that this feature article will provide a valuable resource to the synthetic front for future aspiration in this burgeoning field.
