## Selective photocatalytic production of CH<sub>4</sub> using Zn-based polyoxometalate as a nonconventional CO<sub>2</sub> reduction catalyst†

Nayeong Kim,<sup>ab</sup> Jung Seung Nam,<sup>cd</sup> Jinhyeong Jo,<sup>a</sup> Junmo Seong,<sup>c</sup> Hyunwoo Kim,<sup>ab</sup> Youngkook Kwon,<sup>be</sup> Myoung Soo Lah,<sup>cd</sup> Jun Hee Lee,<sup>\*a</sup> Tae-Hyuk Kwon<sup>cd</sup> and Jungki Ryu<sup>ab</sup>

**Efficient and selective production of CH<sub>4</sub> through the CO<sub>2</sub> reduction reaction (CO<sub>2</sub>RR) is a challenging task due to the high amount of energy consumption and various reaction pathways. Here, we report the synthesis of Zn-based polyoxometalate (ZnPOM) and its application in the photocatalytic CO<sub>2</sub>RR. Unlike conventional Zn-based catalysts that produce CO, ZnPOM can selectively catalyze the production of CH<sub>4</sub> in the presence of an Ir-based photosensitizer (Tlr3) through the photocatalytic CO<sub>2</sub>RR. Photophysical and computation analyses suggest that selective photocatalytic production of CH<sub>4</sub> using ZnPOM and Tlr3 can be attributed to (1) the exceptionally fast transfer of photogenerated electrons from Tlr3 to ZnPOM through the strong molecular interactions between them and (2) effective transfer of electrons from ZnPOM to \*CO intermediates due to significant hybridization of their molecular orbitals. This study provides insights into the design of novel CO<sub>2</sub>RR catalysts for CH<sub>4</sub> production beyond the limitations in conventional studies that focus on Cu-based materials.**

### New concepts

There have been fundamental limitations to the selection of elements for the design and synthesis of CO<sub>2</sub>RR catalysts. For example, metallic Zn or Zn-based materials are known as CO producing catalysts, and CH<sub>4</sub> producing catalysts have been limited to Cu-, Ru- and Ir-based materials. To the best of our knowledge, this is the first report that Zn-based materials including POMs can be used as a CH<sub>4</sub> producing catalysts. Our study suggests that the overlap between the orbitals of catalytic elements and intermediate species (e.g., Zn in ZnPOM and \*CO) plays a significant role in multistep electrochemical reactions such as the CO<sub>2</sub>RR. Conventionally, the underlying mechanism for the CO<sub>2</sub>RR has been explained mostly in terms of the binding energy between catalysts and intermediate species. This is also why there have been fundamental limitations on the selection of elements for the design and synthesis of CO<sub>2</sub>RR catalysts. In this regard, our study provides insights and broadens the material library for the design and synthesis of novel CO<sub>2</sub>RR catalysts, especially for the selective production of hydrocarbons including CH<sub>4</sub>. Considering that POMs can be considered as a 0-D nanomaterial with a well-defined structure, this study can offer a basis for understanding the structure-performance relationship of nanocatalysts.

## Introduction

The carbon dioxide (CO<sub>2</sub>) reduction reaction (CO<sub>2</sub>RR) into valuable chemicals using renewable energy resources is a promising

technology for both ensuring sustainable growth and mitigating environmental problems.<sup>1–4</sup> In principle, useful chemicals, such as carbon monoxide (CO), formic acid (HCOOH), and hydrocarbons, can be produced and consumed in a carbon-neutral manner by exploiting the CO<sub>2</sub>RR.<sup>5–7</sup> Despite recent important progress, the CO<sub>2</sub>RR is a still challenging task that consumes a large amount of energy and results in low product yield/selectivity for a specific chemical. The difficulty stems from the high stability of CO<sub>2</sub> molecules, the complexity of the CO<sub>2</sub>RR involving the transfer of multiple protons and electrons, and the presence of competing reactions.<sup>8–10</sup> These problems necessitate the development of efficient and selective catalysts for the CO<sub>2</sub>RR.<sup>11–16</sup> However, there have been fundamental limitations to the selection of elements in the design and synthesis of CO<sub>2</sub>RR catalysts (Scheme 1a). For example, most transition metals (coloured grey in Scheme 1a) favor hydrogen evolution reactions (HERs) rather than the CO<sub>2</sub>RR. Among diverse chemicals

**Scheme 1** Production of various chemicals from the CO<sub>2</sub>RR. (a) Classification of the main chemical produced by each element in the periodic table through the CO<sub>2</sub>RR: hydrogen (grey), CO (pink), formic acid (green), and hydrocarbons (purple). (b) Structure of ZnPOM and its application as a CO<sub>2</sub>RR catalyst for the selective production of CH<sub>4</sub>.

from the CO<sub>2</sub>RR, the production of hydrocarbons requires the formation of multiple stable intermediate states and the incorporation of more electrons and protons than other CO<sub>2</sub>RR products. For example, eight electrons and protons are required to produce CH<sub>4</sub>, whereas only two are required to produce CO or HCOOH. As a result, only a few elements, such as Cu,<sup>17</sup> Ru,<sup>18</sup> and Ir,<sup>19</sup> are available for the design of the CO<sub>2</sub>RR catalysts for CH<sub>4</sub> production (purple), whereas more diverse elements are available for CO (pink) and HCOOH (green). In this regard, the development of CO<sub>2</sub>RR catalysts for CH<sub>4</sub> production has been mostly focused on Cu-based materials due to their low cost.<sup>20–22</sup>

On the other hand, polyoxometalates (POMs) are considered promising electrocatalysts due to their molecular nature with uniform active sites, structural diversity, and rich electrochemistry.<sup>23</sup> In particular, sandwich-type POMs have been demonstrated as efficient and robust multi-electron transfer catalysts because they can stably embed various transition metal ions between metal oxide clusters.<sup>24,25</sup> For example, it is reported that POMs can serve as homogeneous water splitting catalysts: POMs with Co- and Ru-based active sites for oxygen evolution reactions<sup>26,27</sup> and POMs with Mn-, Ni-, and Cu-based ones for the HER.<sup>28–30</sup> In addition, POMs can rapidly scavenge photogenerated charge carriers from light harvesting materials through strong electrostatic interactions and allow effective photochemical water splitting.<sup>31–34</sup> Despite such unique and promising features, POMs have rarely been studied as CO<sub>2</sub>RR catalysts; even POMs with a Cu-based active site were only tested for the HER.<sup>30</sup> Among the reported POMs for the CO<sub>2</sub>RR, only a few POMs, which have highly complicated structures and are thus very difficult to synthesize, allow CH<sub>4</sub> production while most POMs can catalyse CO production more efficiently than CH<sub>4</sub>.<sup>35–37</sup>

In this study, we first report the synthesis of a simple Zn-based POM (ZnPOM) and its application in a selective photochemical CO<sub>2</sub>RR to CH<sub>4</sub>. ZnPOM was readily prepared under mild conditions and its molecular structure was investigated using

X-ray diffraction (XRD), X-ray photoelectron spectroscopy (XPS), and extended X-ray absorption fine structure (EXAFS) analyses. ZnPOM showed catalytic activity for the CO<sub>2</sub>RR and allowed highly selective CH<sub>4</sub> production under visible light irradiation in the presence of Ir-based photosensitizers (TlIr3). The selectivity against CH<sub>4</sub> was 97.8% when ZnPOM was used as a CO<sub>2</sub>RR catalyst (Scheme 1b). Static and time-resolved photoluminescence analyses revealed that photoexcited electrons of TlIr3 photosensitizers rapidly transfer to ZnPOM. Density of states (DOS) calculations showed that ZnPOM can have strong electronic interactions with a bound CO intermediate (\*CO) due to the significant overlap of the d-orbital of Zn in ZnPOM and the p-orbital of C in \*CO, while metallic Zn cannot due to having no overlap. This explains how Zn—known as a CO-producing catalyst<sup>38,39</sup>—in ZnPOM can lead to selective production of CH<sub>4</sub>. This study provides insights for more flexible design and synthesis of CO<sub>2</sub>RR catalysts, especially for CH<sub>4</sub> production.

## Results and discussion

We synthesized ZnPOM with a molecular formula of [Zn<sub>4</sub>(PW<sub>9</sub>O<sub>34</sub>)<sub>2</sub>]<sup>10-</sup> for the CO<sub>2</sub>RR. There are a family of sandwich-type phosphotungstate POMs ([M(II)<sub>4</sub>(PW<sub>9</sub>O<sub>34</sub>)<sub>2</sub>]<sup>10-</sup>) embedded with various transition metal ions [M(II)=Co<sup>2+</sup>, Ni<sup>2+</sup>, Mn<sup>2+</sup>, Cu<sup>2+</sup>] (MPOM). However, to the best of our knowledge, there is no report on the synthesis of sandwich-type POMs with Zn ions. Conventionally, Zn- and Cu-based materials are known to produce CO and hydrocarbons, respectively, upon the CO<sub>2</sub>RR. Thus, we prepared ZnPOM and CuPOM and compared their catalytic activity for the CO<sub>2</sub>RR (Scheme 1b). It is expected that ZnPOM can be prepared by the same method for the synthesis of CuPOM, which was reported by Hill *et al.*,<sup>30</sup> due to the similarity between Zn and Cu ions in terms of valence charge and ionic radius (74 and 73 pm, respectively).

First, we investigated the properties and molecular structure of ZnPOM by using various characterization methods. The as-prepared ZnPOM was completely dissolved in an aqueous solution (Fig. S1, ESI†). According to dynamic light scattering and zeta potential (Fig. 1a) analyses, the average diameter and zeta potential of ZnPOM were 0.83 nm and -26.13 mV, respectively. These results are consistent with those of other sandwich-type POMs<sup>29</sup> and confirm the molecular nature of ZnPOM rather than the particulate counterpart. XPS analysis confirmed the presence of Zn, W, K, and O atoms of ZnPOM (Fig. S2, ESI†). However, P was not identified possibly due to its relatively low content. Fourier-transform infrared (FT-IR) spectroscopy also showed peaks corresponding to P–O and W–O bands of sandwich-type POMs (Fig. S3, ESI†).<sup>30</sup> To investigate the molecular structure of ZnPOM, we obtained crystallographic data using single crystal XRD after the crystallization of supersaturated ZnPOM from hot water (Table S1, ESI†). As expected, the crystal structure and atomic arrangement of ZnPOM (K<sub>10</sub>[Zn<sub>4</sub>(H<sub>2</sub>O)<sub>2</sub>(PW<sub>9</sub>O<sub>34</sub>)<sub>2</sub>]<sub>·</sub>24H<sub>2</sub>O) were almost identical to those of CuPOM, except for the types of transition metal ions embedded in metal-oxo clusters (*i.e.*, Zn<sup>2+</sup> *vs.* Cu<sup>2+</sup>). The simulated XRD pattern from the single crystal XRD analysis well matched the measured

**Fig. 1** Characterization of ZnPOM. (a) Dynamic light scattering (left) and zeta potential (right) analyses of ZnPOM. (b) Simulated and measured XRD patterns of ZnPOM. (d) A graphical illustration showing the molecular structure of ZnPOM and coordination environment of  $Zn^{2+}$  ions in ZnPOM.

powder XRD pattern (Fig. 1b). ZnPOM was further characterized by EXAFS analysis to check the coordination environment of Zn ions in ZnPOM (Fig. 1c and d, ESI<sup>†</sup>). The distances between  $Zn^{2+}$  and the nearest neighbouring elements in ZnPOM were 1.5 (Zn–O), 2.88 (Zn–W1), and 3.37 Å (Zn–W2), which were similar to those in CuPOM, respectively (Fig. S4, ESI<sup>†</sup>). All these results confirmed the successful synthesis of molecular CuPOM by the same method as that of ZnPOM. High purity of the synthesized ZnPOM (>99.9%) was confirmed by  $^{31}P$  NMR (Fig. S5, ESI<sup>†</sup>).

Next, physicochemical properties of ZnPOM were investigated for the CO<sub>2</sub>RR. First, cyclic voltammetry (CV) of ZnPOM was conducted in 0.1 M KHCO<sub>3</sub> saturated with Ar or CO<sub>2</sub> gas (Fig. 2a). For both cases, there was rapid increase of current density without saturation at highly negative potentials possibly due to the HER. However, there was a pair of redox peaks at around  $-0.5$  V vs. a reversible hydrogen electrode (RHE;  $-0.9$  V vs. standard hydrogen electrode [SHE]) only when CO<sub>2</sub> was purged, suggesting a possibility of ZnPOM as a CO<sub>2</sub>RR catalyst. Encouraged by these results, we carried out photochemical CO<sub>2</sub>RR using ZnPOM in the presence of Ir-based photosensitizers (TlIr3) because ZnPOM has no or a negligible absorbance in the visible light region (Fig. 2b and Fig. S6, ESI<sup>†</sup>). TlIr3 was chosen as a photosensitizer because it has sufficiently high reducing power for the CO<sub>2</sub>RR with the lowest unoccupied and highest occupied molecular orbital (LUMO and HOMO) levels of  $-3.08$  and  $-5.62$  eV vs. vacuum ( $-1.36$  and  $1.18$  V vs. SHE), respectively.<sup>40</sup> TlIr3 had strong absorption in the UV and visible light region up to 500 nm. Interestingly, the absorbance of TlIr3 with ZnPOM was significantly higher than their respective absorbance and arithmetic sum (Fig. 2b), suggesting strong molecular interactions between positively charged TlIr3 and negatively charged ZnPOM. The

**Fig. 2** Photochemical CO<sub>2</sub>RR using ZnPOM as a catalyst and TlIr3 as a photosensitizer. (a) CV analysis of ZnPOM in 0.1 M KHCO<sub>3</sub> saturated with Ar or CO<sub>2</sub> gas. (b) UV/visible absorbance spectra of each component and both in 0.1 M KHCO<sub>3</sub>. (c) Production and (d) selectivity of various chemicals upon photochemical CO<sub>2</sub>RR using 30  $\mu$ M ZnPOM, 0.1 mM TlIr3, and 0.05 M Na<sub>2</sub>SO<sub>3</sub> under visible light irradiation. The selectivity of each product was calculated after 6 h of photochemical CO<sub>2</sub>RR by considering the number of electrons required to produce each.

wavelength-dependent apparent quantum yield of our photocatalytic CH<sub>4</sub> production system showed the maximum efficiency at 400 nm and was in accordance with the absorbance spectra (Fig. S7, ESI<sup>†</sup>). CV analysis showed that TlIr3 has no activity towards the CO<sub>2</sub>RR and can strongly interact with ZnPOM, as can be expected from the increase of current density of the redox pair at around  $-0.5$  V vs. RHE in the presence of both (Fig. S8, ESI<sup>†</sup>). On the other hand, CuPOM had not only a negligible absorbance in the visible light region but also weak interactions with TlIr3 in terms of absorbance (Fig. S9, ESI<sup>†</sup>).

Photochemical reactions were conducted using ZnPOM (or CuPOM) to check its activity as a CO<sub>2</sub>RR catalyst without any external bias. TlIr3 and Na<sub>2</sub>SO<sub>3</sub> were used as a photosensitizer and a sacrificial electron donor, respectively. Under the optimum conditions with TlIr3 at 0.1 mM, ZnPOM at 30  $\mu$ M, and Na<sub>2</sub>SO<sub>3</sub> at 50 mM, only CH<sub>4</sub> was selectively produced with negligible or erroneous amounts of H<sub>2</sub> and CO (Fig. S10, ESI<sup>†</sup>). Under continuous visible light irradiation, the amount of CH<sub>4</sub> linearly increased and reached 4.16  $\mu$ mol per unit mass of ZnPOM after 6 h (Fig. 2c). There were no other liquid products. Although the CH<sub>4</sub> production yield of this study is not record-high, it was comparable to those in previous reports on the photocatalytic CO<sub>2</sub>RR (Table S2, ESI<sup>†</sup>). The product selectivity of ZnPOM towards a certain chemical (A) was calculated using the following equation that considers the number of electrons ( $n$ ) required to make each product (Fig. 2d):

$$\text{Selectivity (\%)} \text{ for } A = \frac{\text{mole of } A \times n}{(\text{mole of CH}_4 \times 8) + (\text{mole of CO} \times 2) + (\text{mole of H}_2 \times 2)}$$

where  $n$  is 2 for  $\text{H}_2$  and  $\text{CO}$ , and 8 for  $\text{CH}_4$ . Surprisingly, the selectivity of ZnPOM against  $\text{CH}_4$  was 97.8% whereas those against  $\text{CO}$  and  $\text{H}_2$  were only 3.0 and 2.3%, respectively. The stability of ZnPOM was studied by a recycling test (Fig. S11, ESI<sup>†</sup>). There was no noticeable decrease of  $\text{CH}_4$  production yield until the third cycle. Because Ir is also known to generate  $\text{CH}_4$ ,<sup>19</sup> we carried out photochemical CO2RR reactions without ZnPOM. TIr3 alone showed no activity for the CO2RR and led to the production of hydrogen only (Fig. S12, ESI<sup>†</sup>). For comparison, CuPOM, CoPOM, and NiPOM were also tested for photochemical CO2RR under the same conditions (Fig. S13 and S14, ESI<sup>†</sup>). Although CuPOM also allowed the production of  $\text{CH}_4$ , it was much less efficient than ZnPOM in terms of productivity (0.42 vs. 4.16  $\mu\text{mol g}^{-1}$  for 6 h) and selectivity (69.5 vs. 97.8%). However, CoPOM<sup>26</sup> and NiPOM<sup>29</sup> exhibited poor performance for the CO2RR, as expected from the previous reports about their application in oxygen and hydrogen evolution reactions, respectively. As shown in the absorbance measurement above, ZnPOM (Fig. 2b) showed stronger electrostatic interactions with TIr3 than CuPOM (Fig. S9, ESI<sup>†</sup>). This partly explains why ZnPOM exhibited a higher activity than CuPOM for photocatalytic CO2RR to  $\text{CH}_4$ . Taken together, these results indicate that ZnPOM acts as an electrocatalyst for  $\text{CH}_4$  production. These are very interesting results in the sense that metallic Zn and Cu are known to produce CO and hydrocarbons upon the CO2RR, respectively.

Static and dynamic photoluminescence quenching analyses were performed to confirm the electron transfer pathway in our photocatalytic system. Strong photoluminescence of TIr3 in the range of 500–700 nm was dramatically quenched as the concentration of ZnPOM increased (Fig. 3a). Photoluminescence of TIr3 disappeared immediately after the addition of ZnPOM, which can be observed even by the naked eye. Because the LUMO level of TIr3 (−0.8 V vs. RHE) is more negative than that of ZnPOM (−0.6 V vs. RHE), one can expect that photoexcited electrons from TIr3 can be transferred to ZnPOM, resulting in photoluminescence quenching (Fig. S8b and c, ESI<sup>†</sup>). To quantify the charge transfer dynamics, the photoluminescence lifetime of TIr3 was recorded in the absence and presence of an electron donor ( $\text{Na}_2\text{SO}_3$ ) or ZnPOM (Fig. 3b). The photoluminescence lifetime of TIr3 dramatically decreased from 820 to 64 ns after the addition of ZnPOM, which well agrees with the static photoluminescence quenching results. In contrast, there was little change in the lifetime after the addition of  $\text{Na}_2\text{SO}_3$ , which rules out the reductive quenching pathway of TIr3. Thus, we can conclude that the main charge transfer pathway in this catalytic network follows the oxidative quenching pathway (Fig. 3c). Based on the ratio between the photoluminescence of TIr3 without ( $I_0$ ) and with ZnPOM ( $I$ ), the bimolecular rate constant ( $K_{\text{SV}}$ ) was calculated from the Stern–Volmer equation (Fig. S15, ESI<sup>†</sup>).  $K_{\text{SV}}$  for TIr3 and ZnPOM was  $1.76 \times 10^{11} \text{ M}^{-1} \text{ s}^{-1}$ , which is remarkably fast compared to those in previously reported catalytic systems (Table S3, ESI<sup>†</sup>).

DOS calculations from density functional theory were carried out to unveil the molecular mechanism for the selective production of  $\text{CH}_4$  by ZnPOM. Because metallic Zn and Zn-based materials are known to produce CO,<sup>41,42</sup> we compared the DOS

Fig. 3 Photophysical analysis of photocatalytic CO2RR systems. (a) Static photoluminescence spectra of TIr3 (50  $\mu\text{M}$ ) without (blue line) and with ZnPOM at different concentration ratios of TIr3 and ZnPOM. (b) Time-correlated single-photon counting for lifetime measurements of TIr3 without and with POM or sacrificial electron donor (E.D.)  $\text{Na}_2\text{SO}_3$ . (c) A suggested mechanistic pathway for the photocatalytic CO2RR to  $\text{CH}_4$  using ZnPOM and TIr3.

of Zn ions in ZnPOM with that of metallic Zn. In addition, one of the most important factors determining the products of the CO2RR is electronic interactions between catalysts and intermediate states.<sup>21,43</sup> In particular,  $^*\text{CO}$  is an important intermediate for the production of  $\text{CH}_4$ . Our calculations showed that the DOS of the Zn atom (d-orbital) in ZnPOM significantly overlaps with that of the C atom (p-orbital) in  $^*\text{CO}$  (Fig. 4a). In contrast, the DOS of the metallic Zn does not overlap with that of the C atom (p-orbital) in  $^*\text{CO}$  (Fig. 4b). Thus, one can expect that the strong electronic hybridization between ZnPOM and the  $^*\text{CO}$  intermediate allows the facile transfer of electrons for further reactions of  $^*\text{CO}$  to  $\text{CH}_4$ . To investigate the reaction mechanism more in detail, the binding energy between the key intermediate  $^*\text{CO}$  and POMs was calculated (Fig. 4c). The binding energies of CuPOM, ZnPOM, and CoPOM were  $-0.48$ ,  $-0.24$ , and  $+0.57$  eV, respectively. Our results are consistent with the previous report on the relationship between the  $^*\text{CO}$  binding energy and product selectivity in the CO2RR.<sup>1</sup> While CuPOM strongly binds to  $^*\text{CO}$  led to competition between the HER and CO2RR, CoPOM, which cannot easily bind with  $^*\text{CO}$ , has poor activity for the CO2RR (Fig. S14, ESI<sup>†</sup>). In contrast, ZnPOM binding neither too strongly nor too weakly with  $^*\text{CO}$  is advantageous for the selective production of  $\text{CH}_4$ .

In this study, we first report the synthesis of ZnPOM as a CO2RR catalyst for the selective production of  $\text{CH}_4$  upon

**Fig. 4** DFT calculations of density of states and \*CO binding energy of the respective materials. (a) The calculated DOS of the p-orbital of C in \*CO and d-orbital of Zn in ZnPOM. (b) The calculated DOS of the p-orbital of C in \*CO and d-orbital of Zn in metallic Zn. The insets show preferred products from the CO2RR by each catalyst (*i.e.*, ZnPOM and Zn). photocatalytic CO2RR. Conventionally, metallic Zn or Zn-based materials are known as CO producing catalysts, and CH<sub>4</sub> producing catalysts have been limited to Cu-based materials. Although the efficiency of our catalyst should be further improved for practical application, this is the first report that Zn-based POMs can be used as a CH<sub>4</sub> production catalyst. In this regard, this study provides insights and broadens the material library for the synthesis of novel CO2RR catalysts, especially for the selective production of hydrocarbons including CH<sub>4</sub>. Our analyses based on the absorbance and photoluminescence measurements suggest that strong molecular interactions exist between ZnPOM and TiIr3. Different CO2RR activity of Zn—known to produce CO—and ZnPOM was also investigated with DOS calculations, which show significant overlap between the d-orbital of Zn<sup>2+</sup> in ZnPOM and the p-orbital of C in \*CO. Considering that \*CO is an important intermediate for the production of CH<sub>4</sub> and sandwich-type POMs can facilitate multiple electron transfer,<sup>27</sup> these results explain why ZnPOM can selectively produce CH<sub>4</sub> upon photochemical CO2RR.

## Conclusions

To summarize, we first report the synthesis of ZnPOM and introduce a photochemical CO2RR system using ZnPOM as a CO2RR catalyst and TiIr3 as a photosensitizer. According to the absorbance and quenching analyses, strong molecular interactions occurred between ZnPOM and TiIr3, resulting in an exceptionally high bimolecular rate constant and rapid transfer of photoexcited electrons from TiIr3 to ZnPOM. According to density functional theory calculations, ZnPOM can have electronic interactions with \*CO due to the significant overlap of the DOS between Zn ions in ZnPOM and C in \*CO. As a result, ZnPOM can selectively produce CH<sub>4</sub> upon the photochemical CO2RR. Our results provide insights for the synthesis of cheap and efficient CO2RR catalysts using ZnPOM, especially for CH<sub>4</sub> production.

## Experimental

### Materials

ZnCl<sub>2</sub> and KCl were purchased from Alfa Aesar (USA). Na<sub>2</sub>WO<sub>4</sub>·2H<sub>2</sub>O, acetic acid, and Na<sub>2</sub>SO<sub>3</sub> were obtained from Sigma-Aldrich (USA). Na<sub>2</sub>HPO<sub>4</sub> was purchased from VWR Life Science.

### Synthesis of [PW<sub>9</sub>O<sub>34</sub>]<sup>9-</sup>

Na<sub>2</sub>WO<sub>4</sub>·2H<sub>2</sub>O (120 g) was dissolved in 150 mL of deionized water. Then, 8.17 g of Na<sub>2</sub>HPO<sub>4</sub> and 22 mL of acetic acid were added into the Na<sub>2</sub>WO<sub>4</sub> solution. After 1 min, a white precipitate of [PW<sub>9</sub>O<sub>34</sub>]<sup>9-</sup> was formed, collected by vacuum filtration, and heated at 140 °C for 6 h in air.

### Synthesis of K<sub>10</sub>[Zn<sub>4</sub>(H<sub>2</sub>O)<sub>2</sub>(PW<sub>9</sub>O<sub>34</sub>)<sub>2</sub>]·24H<sub>2</sub>O

ZnCl<sub>2</sub>·2H<sub>2</sub>O (0.99 g) was dissolved in 12 mL of deionized water. Then, 5.1 g of [PW<sub>9</sub>O<sub>34</sub>]<sup>9-</sup> was added into the ZnCl<sub>2</sub> solution and stirred for 10 min. After adding 1 g of KCl, a white precipitate of K<sub>10</sub>[Zn<sub>4</sub>(H<sub>2</sub>O)<sub>2</sub>(PW<sub>9</sub>O<sub>34</sub>)<sub>2</sub>]·24H<sub>2</sub>O formed and was collected by vacuum filtration.

### Synthesis of TiIr3

TiIr<sub>3</sub> was prepared according to a previously reported paper.<sup>40</sup> Briefly, IrCl<sub>3</sub>·H<sub>2</sub>O (298 mg, 1.00 mmol) and 2-phenylquinaline (431 mg, 2.10 mmol) were dissolved in a mixture of 2-methoxyethanol and H<sub>2</sub>O (3:1, v/v%) and refluxed for 24 h. After cooling to room temperature, distilled water was poured to form reddish brown precipitates. The precipitates were filtered and washed with distilled water, *n*-hexane, and cooled ether, respectively. The crude product of di- $\mu$ -chlorotetrakis[2-(2-quinolinyl-*N*)phenyl-C] diiridium(III) was acquired and used without any further purification (401 mg, 63.0%). Di- $\mu$ -chlorotetrakis[2-(2-quinolinyl-*N*)phenyl-C]diiridium(III) (150 mg, 0.123 mmol) and 2,2'-bipyridine (39 mg, 0.25 mmol) were dissolved in a mixture of dichloromethane and methanol (1:1, v/v%), refluxed overnight, concentrated *in vacuo*, and then re-dissolved in ethanol. Undissolved solid was filtered out and filtrate was concentrated *in vacuo* again. The orange product of TiIr<sub>3</sub> was obtained after the precipitation process with methylene chloride and *n*-hexane (137 mg, 70.2%).

## Elemental and structural characterization

The elemental composition of ZnPOM was characterized by K-alpha X-ray photoelectron spectroscopy (XPS) (Thermo Fisher Scientific, USA). FT-IR spectra were measured on a Varian 670-IR (Agilent Technologies, USA) using KBr pellets. UV/visible absorbance of each material was confirmed with a V-730 UV-Visible spectrophotometer (JASCO, Japan). For X-ray diffraction (XRD) analysis, microcrystals of ZnPOM were obtained by crystallization in the supersaturated solution. Single-crystal and powder XRD data were collected by an R-AXIS RAPID II (Rigaku, Japan) and a powder XRD D2 PHASER (Bruker, USA), respectively. Extended X-ray absorption fine structure (EXAFS) analysis was performed at the beamline 6D of the Pohang Light Source in the Pohang Accelerator Laboratory in Korea. The ZnPOM particle size was analysed with a Zeta sizer (Malvern, England).  $^{31}\text{P}$  NMR spectra were collected by an AVANCE III HD (Bruker, USA).

## Electrochemical and photochemical characterization

Cyclic voltammetry (CV) was carried out with a WMOG1000 multichannel potentiostat (WonA Tech CO. Ltd, Korea) in a three-electrode configuration: a working electrode, glassy carbon; a reference electrode, Ag/AgCl; a counter electrode, fluorine-doped tin oxide coated with 100 nm thick Pt; electrolyte, 0.1 M  $\text{KHCO}_3$  (pH 7.0) saturated with Ar or  $\text{CO}_2$  gas; and scan rate, 10 mV s $^{-1}$ . For the optimal photochemical CO2RR, 4 mL of a 0.1 M  $\text{KHCO}_3$  solution with 30  $\mu\text{M}$  ZnPOM, 0.1 mM Ir-complex, and 0.05 M  $\text{Na}_2\text{SO}_3$  in 0.1 M  $\text{KHCO}_3$  was used in a 10 mL vial. Gas products were collected from a sealed reaction vessel using an air-tight syringe (1 mL) and analysed with a GC-2010 plus gas chromatograph (Shimadzu Co., Japan) equipped with an FID and MICROPACKED ST column (Shinwa Chemical Industries Ltd, Japan). Product yields were calculated by dividing the amount of products by the amount of catalyst. Liquid products were measured using a Water 2410 HPLC (Waters, USA). A 300 W Xe lamp equipped with a 400 nm cut-on filter (100 mW cm $^{-2}$ ) was used as a light source.

## Photoluminescence quenching analysis

TIr3 (50  $\mu\text{M}$ ) was mixed with POM at molar ratios of 1:0, 1:0.1, 1:0.5, and 1:1 in distilled water. The photoluminescence intensity of the prepared solutions was recorded with a FLS920 (Edinburgh Instruments, UK) and a PC1 (ISS, USA). Bimolecular rate constant (KSV) from photoluminescence quenching was calculated through Stern–Volmer plot by maximum photoluminescence intensity for each mixture ratio.

## Time-correlated single photon counting for lifetime measurements

The photoluminescence lifetime of TIr3 was recorded with and without potential quenchers (e.g., ZnPOM or  $\text{Na}_2\text{SO}_3$ ) using a FluoTime300 time-correlated single photon counting setup (TCSPC) (PicoQuant, Berlin, Germany). A LDH-D-C-450 pulsed diode laser coupled with a PDL 820 laser diode driver (<70 ps pulse width and 196 kHz–40 MHz repetition rate) was used as a photoexcitation source. The time-resolved exciton decay was measured with a PicoHarp 300E TCSPC module and a PMA-C

182-N-M photomultiplier tube. Fitting was carried out using FluoFit software to calculate the corresponding photoluminescence lifetimes.

## Density functional theory calculations

The Vienna Ab initio Simulation Package (VASP)<sup>44</sup> was used to calculate relaxed structures and density of states. The generalized gradient approximation (GGA) method was adopted to describe the exchange correlation functional. The pseudopotentials generated under the projector-augmented wave (PAW) method<sup>45</sup> were used and the energy cutoff for the plane wave basis set was set to 500 eV. The force criterion for optimizing the atomic positions was  $5 \times 10^{-3}$  eV Å $^{-1}$ .

## Conflicts of interest

There are no conflicts to declare.
