# Energy augmentation of triboelectric nanogenerators using PDMS–MWCNT composites and their applications in IoT and HMI sensing†

Shailendra Kumar,<sup>\*a</sup> Tarun Pratap Singh,<sup>b</sup> Rajesh Kumar Jha,<sup>id a</sup> Prashant Sharma,<sup>a</sup> Sumit Sinha-Ray<sup>c</sup> and Ankur Goswami<sup>id \*a</sup>

Triboelectric nanogenerators (TENGs) have become viable self-powered systems, with great potential to satisfy the increasing demand for portable and adaptable power sources. Using these systems, mechanical vibrations from the motion of vehicles, human beings, rain falls, ocean waves, and air flows can be efficiently captured. Depending on the triboelectric series, various materials have been used and explored for TENG applications. In this work, we investigated the triboelectric characteristics of spin-coated polydimethylsiloxane (PDMS) and multiwall carbon nanotube (MWCNT) composite membranes. By adding various concentrations of MWCNTs in PDMS, the charge transfer efficiency was investigated in terms of the current output. At the optimized composition of 0.05 wt% MWCNTs in PDMS, an open-circuit voltage ( $V_{oc}$ ) of 110 V and a short-circuit current ( $I_{sc}$ ) of 10  $\mu$ A were observed leading to a power density of nearly 1  $W m^{-2}$ . Additionally, this composition demonstrated outstanding long-term durability and electrical stability, facilitating energy harvesting during routine activities like jogging and walking using clothing and shoes.

## 1. Introduction

As an alternate way for powering portable gadgets, healthcare equipment, and wireless sensor systems, energy-harvesting technologies have attracted significant attention in recent years.<sup>1,2</sup> Extensive studies have been devoted to the field of wearable devices to harness energy from human motion.<sup>3–6</sup> In particular, recent years have seen a surge in the research on

Tarun Pratap Singh earned his BTech degree from the National Institute of Technology (NIT), Uttarakhand, in 2017 and completed his MTech degree at Indian Institute of Technology (IIT) Mandi in 2020. Since 2023, he has been pursuing his PhD degree at Indian Institute of Technology (IIT) Delhi, India. His research interests include triboelectric nanogenerators and fabrication of nano- and micro-fibers using techniques such as electrospinning, solution-blowing, and supersonic-blowing processes.

the use of triboelectric nanogenerators (TEGs) to convert the motions of the human body into electric energy for use in power portable devices, internet of things (IoT) gadgets and water proof textiles.<sup>7</sup> TEGs are flexible, efficient, and cost-effective energy harvesters.<sup>8,9</sup> One of the most significant obstacles that must be overcome to produce flexible energy-harvesting devices is the selection of suitable materials that can provide both flexibility and mechanical stability.<sup>10–12</sup> Additionally, the design and construction of the whole structure must be accomplished. Significant efforts have been devoted to improve the performance of flexible TEGs over the last decade, with the intention of broadening their applications. Polydimethylsiloxane (PDMS) is recognized as one of the most durable organic, nonmetallic, and flexible materials. This makes it highly suitable for use as a triboelectric material, typically classified within the series of tribo-negative materials. It features great flexibility, stretchability, and biocompatibility, which are necessary for wearable energy harvesters.<sup>12,13</sup> Furthermore, PDMS possesses very high dielectric constant characteristics, which allow it to simultaneously absorb and store the electrostatic charges that are formed during the triboelectric process. This generation of the charge because of their difference in electronegativity is referred to as the triboelectric process, which arises from the difference in electronegativity between contacting materials. It has been shown in several studies that the energy-conversion capabilities of these devices can be enhanced *via* surface modification through the process of nano-structuring, which typically involves increasing the surface area of the parent matrix of the TEGs. There have been many studies that have demonstrated an increase in the energy-conversion efficiency of PDMS-based TEGs, using several types of conductive materials.<sup>14,15</sup> Multiwall carbon nanotubes, also known as MWCNTs, are one of the most effective materials for improving the electrical characteristics of materials. The atomic structure of MWCNTs is one of a kind, and as a result, they boast outstanding mechanical strength, electrochemical stability, electrical conductivity, and

thermal resistance.<sup>16–18</sup> As a result of the incorporation of MWCNTs into PDMS, the surface charge density and ability to transfer charge can be significantly boosted, which ultimately results in enhanced performance across a variety of applications. Within the context of PDMS-based materials, this combination makes use of the remarkable properties of MWCNTs to improve the overall functioning and longevity of products.

MWCNTs have emerged as potential conductive materials for improving the performance output of triboelectric nanogenerators (TEGs). Recently, Salaudin *et al.* proposed a TENG utilizing MXene-integrated eco-flex composites encased in fabric, with MXene functioning as the tribo-negative layer. The device attained a maximum output power of 3.69 mW at an input impedance of 4.5 M $\Omega$ , with an applied force of 8 N and a frequency of 4.5 Hz.<sup>19</sup> In a similar way, Yang *et al.* engineered a flexible hybrid nanogenerator that integrated piezoelectric and triboelectric elements in an Al/PVDF/Cu-PDMS/ITO/PET configuration, achieving a peak current of 20  $\mu$ A, voltage of 88 V, and power output of 98  $\mu$ W.<sup>20</sup> Zhu *et al.* examined PDMS-Ag nanocomposites, yielding an output voltage of 33.6 V, current of 4.5  $\mu$ A, and power density of 162 mW m<sup>-2</sup> at a pressure of 53.57 kPa.<sup>21</sup> In a separate investigation, Hajra *et al.* presented a ZIF-67-based TENG for autonomous robotic object identification, attaining a peak output voltage of 118 V, short-circuit current of 1.7  $\mu$ A, and power density of 0.15 W m<sup>-2</sup>.<sup>22</sup>

The innovation in the present work is the creation of a high-performance, flexible TENG utilizing a PDMS–MWCNT composite membrane, optimized by meticulous regulation of the MWCNT composition. The incorporation of 0.050 wt% MWCNTs into the PDMS matrix significantly enhanced the triboelectric performance of the TENG, resulting in a power density of 0.97 W m<sup>-2</sup>, output voltage of 110 V, and current of 10  $\mu$ A, while also demonstrating exceptional durability over 10 000 operating cycles. The effective incorporation of the TENG into wearable devices for energy harvesting from human motion was demonstrated, underscoring its potential for prac-

tical use in self-powered sensing technologies. This scalable manufacturing approach distinguishes itself from prior research by providing a dependable, robust, and efficient solution for wearable energy harvesting. Additionally, to replicate authentic motion events, we created and evaluated a wearable prototype.

## 2. Results and discussion

### 2.1. Optimization and characterization of TENG

**2.1.1 Structural phase and morphological analysis of the fillers.** Structural characterization of the synthesized PDMS-MWCNT composite membrane was carried out by XRD, as shown in Fig. 1(a). The XRD pattern of the PDMS material displayed a peak at a  $2\theta$  angle of  $11.80^\circ$ .<sup>23,24</sup> Upon incorporating the MWCNTs into PDMS, the XRD pattern of the MWCNT phase aligned with the JCPDS card no. 54-0964. A distinct and well-defined peak corresponding to the C layer could be seen in the XRD pattern of the MWCNTs at a  $2\theta$  angle of  $26^\circ$ , aligned along the preferred direction of the (002) plane.<sup>25</sup> Additionally, the XRD peaks of PDMS decreased in intensity after incorporating the MWCNTs into the composite membrane. Next, the chemical bond and structure of the composite membrane were investigated using FTIR. When the sample was exposed to infrared light, it showed clear peaks, indicating the presence of several chemical connections. Fig. 1(b) shows a prominent peak could be observed at  $784.08\text{ cm}^{-1}$ , which was related to the oscillatory movement of  $\text{Si}(\text{CH}_3)_2$ . The existence of Si-C bonds in the PDMS-MWCNT composite membrane was confirmed by the peak at  $843.8\text{ cm}^{-1}$ . The detection of Si-O-Si stretching in PDMS was identified by a complex signal seen at  $1004.2\text{ cm}^{-1}$ . The occurrence of a peak at  $1256.08\text{ cm}^{-1}$  indicated the existence of a vibration related to the distortion of the  $-\text{CH}_3$  group in PDMS. Moreover, a conspicuous peak at  $2962.02\text{ cm}^{-1}$  could be observed, suggesting the presence of MWCNTs. Next, the Raman spectra of PDMS and the composite membrane were recorded using a 532 nm laser source with a power output of 0.28 mW, as seen in

Fig. 1(c) and in the zoomed-in view in Fig. 1(d). The Raman spectrum of the pure PDMS sample exhibited distinct peaks at specific wavenumbers:  $491.56\text{ cm}^{-1}$  for Si-O-Si symmetric stretching,  $615.48\text{ cm}^{-1}$  for Si-C symmetric stretching,  $709.85\text{ cm}^{-1}$  for Si- $\text{CH}_3$  symmetric rocking,  $1258.92\text{ cm}^{-1}$  for  $\text{CH}_3$  symmetric bending,  $1414.57\text{ cm}^{-1}$  for  $\text{CH}_3$  asymmetric bending,  $2901.85\text{ cm}^{-1}$  for  $\text{CH}_3$  symmetric stretching, and  $2966.21\text{ cm}^{-1}$  for  $\text{CH}_3$  asymmetric stretching.<sup>26</sup> Upon the addition of MWCNTs to the PDMS matrix, similar peaks were seen, but with reduced intensity compared to in the pure PDMS. Furthermore, an additional peak at  $1584.32\text{ cm}^{-1}$  was observed, which could presumably be attributed to the presence of  $\text{sp}^2$  hybridized C=C bonds or the elongation of aromatic rings.<sup>27</sup>

The morphology of the PDMS-MWCNT composite membranes was investigated by SEM imaging, as shown in Fig. 2. The SEM micrographs showed a homogeneous dispersion of MWCNT nanofillers inside the PDMS matrix, indicating that the nanotubes were successfully incorporated into the polymer framework.

**2.1.2. Triboelectric output performance.** The effective area of the contact surfaces and the choice of contact materials are known to significantly affect the output characteristics of a TENG. To evaluate the triboelectric performance, an in-house triboelectric test setup was used here that was specifically designed for operation in the contact-separation (CS) mode.<sup>28</sup> The triboelectric output performance was determined by contact electrification and electrostatic induction. A theoretical model of the contact separation mode TENG (CS-TENG) is illustrated in Fig. 3. This model can be conceptualized as two films with opposing triboelectric properties, each having electrodes attached to their back sides.

The output open-circuit voltage and short-circuit current were calculated using the parallel capacitor model, represented by the “ $V - Q - x$ ” equation.<sup>29,30</sup>

$$V_{\text{output}} = -\frac{Q}{S\epsilon_0} \left( \frac{d_1}{\epsilon_{r1}} + x(t) \right) + \frac{\sigma_{\text{T}} x(t)}{\epsilon_0} \quad (1)$$

**Fig. 2** SEM images of (a) pristine PDMS and (b) 0.05 wt.% MWCNT-doped PDMS.

**Fig. 3** Contact-separation mode TENG: (a) structural design of the device and (b) theoretical model.

In open-circuit conditions  $Q = 0$ , then

$$V_{oc} = \frac{S\sigma_T}{C_{air}} = \frac{\sigma_T x(t)}{\epsilon_0} \quad (2)$$

In short-circuit condition when the output voltage is zero

$$Q_{sc} = \frac{S\sigma_T}{C_{air}C_{total}} = \frac{S\sigma_T x(t)}{d_0 + x(t)} \quad (3)$$

$$I_{sc} = \frac{dQ_{sc}}{dt} = \frac{S\sigma_T d_0 v(t)}{(d_0 + x(t))} \cdot \frac{1}{(d_0 + x(t))} \quad (4)$$

where  $Q$  is the transferred free charge,  $S$  is the contact area,  $d_1$  is the tribolayer thickness,  $\epsilon_{r1}$  is the relative permittivity of the tribolayers,  $\epsilon_0$  is the air permittivity,  $x(t)$  is the separation distance,  $v(t)$  is the vibrational speed, and  $\sigma_T$  is the tribocharge density.

The electrical performances of the TENGs were evaluated by measuring the open-circuit voltage ( $V_{oc}$ ) and short-circuit current ( $I_{sc}$ ) at a frequency of 4.4 Hz, as shown in Fig. 4. The triboelectric output was measured using metal electrodes (copper and aluminium) in contact with the MWCNT-doped PDMS composite membrane. As shown in ESI Table S1 and

Fig. S1,<sup>†</sup> the output performance of the copper and aluminium electrodes was comparable. Thus, copper was chosen as the electrode material for all the further triboelectric performance testing. The top electrode and friction layer had a contact surface dimensions of  $20 \times 20 \text{ mm}^2$ , separated by 6 mm. The output performance was investigated at different wt% of MWCNTs (0.025, 0.050, 0.075, and 0.10 wt%) in the PDMS matrix. The corresponding open-circuit voltage (Fig. 4(a–e)) and short-circuit current (Fig. 4(f–j)) values were recorded as follows: 54, 84, 110, 70, and 62 V, and 5.0, 5.8, 10.0, 6.6, and  $5.8 \mu\text{A}$ , respectively. The highest  $V_{oc}$  ( $\sim 110 \text{ V}$ ) and  $I_{sc}$  ( $\sim 10.0 \mu\text{A}$ ) were achieved at 0.050 wt% MWCNT doping, attributed to the optimized distribution of MWCNTs within the PDMS matrix at this concentration, which facilitated efficient charge transfer. The decrease in  $V_{oc}$  and  $I_{sc}$  were observed at wt% greater than 0.075 wt% due to exceeding the percolation threshold; whereby, beyond the percolation limit, the composite membranes started losing their properties.<sup>31</sup> Notably, the TENG with 0.050 wt% MWCNTs exhibited nearly double the output voltage and current compared to the TENG fabricated with PDMS alone.

Fig. 4 Open-circuit voltage ( $V_{oc}$ ) (a–e) and short-circuit current ( $I_{sc}$ ) (f–j) of different weight percentages of MWCNT-doped PDMS.

We further investigated the output performance of the 0.050 wt% MWCNT-doped PDMS at varying distances between the two triboelectric layers, ranging from 2 to 10 mm, as illustrated in Fig. 5. The highest  $V_{oc}$  and  $I_{sc}$  outputs were observed at a separation distance of 6 mm, as depicted in Fig. 5(a) and (d). Additionally, we studied the effect of different external pressures, ranging from 1 to 20 N. The voltage output reached a maximum of 110 V, while the current peaked at 10  $\mu$ A at an applied force of 15 N, as shown in Fig. 5(b) and (e). Furthermore, we optimized the rotational velocity of the linear motor at four speeds: 20.93, 41.87, 62.8, and 83.73  $\text{rad s}^{-1}$ . The maximum  $V_{oc}$  and  $I_{sc}$  were achieved at a rotational velocity of 62.8  $\text{rad s}^{-1}$ , as illustrated in Fig. 5(c) and (f). Over a frequency range of 1.8 to 4.4 Hz, the open-circuit voltage ( $V_{oc}$ ) and short-circuit current ( $I_{sc}$ ) were recorded in the same way. A  $V_{oc}$  of 55 V and  $I_{sc}$  of 5.5  $\mu$ A seen in the TENG at lower frequencies, while at higher frequencies, these went up to 110 V and 10.0  $\mu$ A, respectively. The related data and graphs can be found in the ESI, in Table S2 and Fig. S2, S3.†

To assess the energy-harvesting capability of the CS-TENG, the relationship between the output voltage ( $V$ ) and load resistance ( $R$ ) was measured, and the power density (P.D) was calculated using the formula  $P.D = V^2/R \cdot A$ , where  $A$  is the device area, as depicted in Fig. 6(a). The P.D was determined at a 6 mm separation between the triboelectric layers and an applied frequency of 4.4 Hz under varying external loads. The output voltage exhibited a steady increase with increasing  $R$  across the entire range. Correspondingly, the power density initially rose with the increasing  $R$ , reaching peak values of 0.2  $\text{W m}^{-2}$  for pure PDMS and 0.98  $\text{W m}^{-2}$  for PDMS containing 0.050 wt% MWCNTs, both at an optimal resistance of 5  $\text{M}\Omega$ . The impedance of the device was further investigated by analyzing the relationship between the voltage, current, and external load, yielding a value of 5  $\text{M}\Omega$ , as shown in Fig. 6(b). The aging effect on the TENG samples was investigated by measuring the output performance parameters weekly for 10 weeks, as illustrated in Fig. 6(c). A gradual decrease of up to 4% of

output was observed after seven weeks. A maximum loss of 20% of the  $V_{oc}$  was noticed after 10 weeks. The device output voltage was recorded across various humidity levels (ranging from 20% to 70%) and over different time intervals (up to 10 weeks) to assess the TENG's long-term stability, as shown in Fig. 6(d). Notably, the TENG generated a voltage of 110 V at 20% humidity, but the device's response significantly declined with increasing humidity. At 70% humidity, the TENG's voltage dropped to 95 V. Generally, higher relative humidity exacerbates the dissipation of triboelectric charges on the friction layers, leading to a general decrease in the output of the TENG. Further, we examined the impact of external forces and constant frequency on its output performance. Additionally, a durability test involving 10 000 cycles was conducted, and the results are presented in Fig. 6(e). Remarkably, there was no degradation in the output response over the entire 10 000 cycles, affirming the robustness of the fabricated TENG. This stability was particularly evident when operating at significantly lower frequencies, with minimal influence of the frequency variations. The obtained output parameters were compared with the existing available PDMS-based TENGs, as shown in Table 1.

Furthermore, the accumulated surface charge of the pure PDMS and 0.050 wt% MWCNTs was calculated using the following equation:<sup>35</sup>

Accumulated charge during one half of the AC cycle: integrates over half a cycle from  $t = 0$  to  $t = T/2$

$$Q_{\text{half}} = \int_0^{T/2} I_{\text{max}} \sin(\omega t) dt \quad (5)$$

Substitute  $\omega = 2\pi f$

$$Q_{\text{half}} = \frac{I_{\text{max}}}{2\pi f} [-\cos(2\pi f t)]_0^{T/2} \quad (6)$$

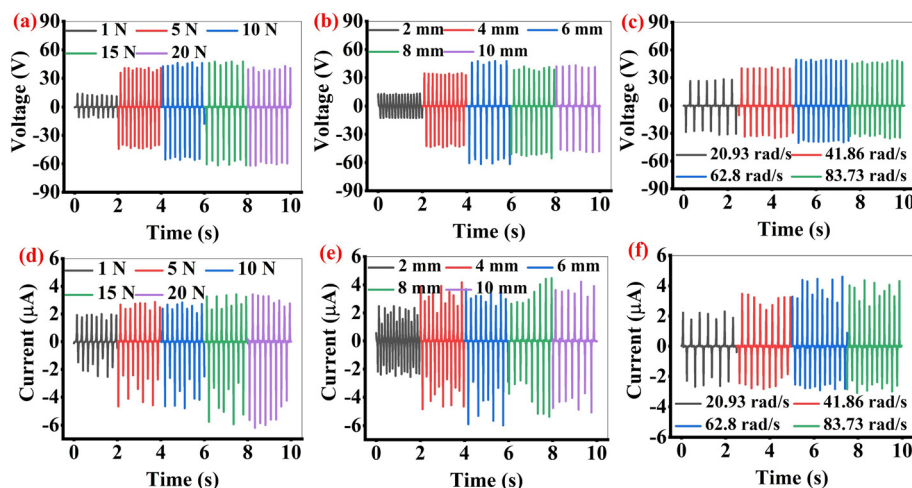

Fig. 5  $V_{oc}$  and  $I_{sc}$  at different applied forces (a and d), different separation distances (b and e), and different angular velocities (c and f).

**Fig. 6** (a) Power density at different load resistances for all the composite membranes, (b) impedance of PDMS–MWCNT (0.050 wt%), (c) durability test of PDMS–MWCNT (0.050 wt%) over 10 weeks, (d) effect of humidity on the output voltage, and (e) durability test for 10 000 cycles.

**Table 1** Performance parameters (area, voltage, current, impedance, and average power density) of selected examples of triboelectric materials based on PDMS composite membranes

Material	Area (cm <sup>2</sup> )	Voltage (V)	Current (μA)	Impedence (MΩ)	Average power density (W m <sup>-2</sup> )	Ref.
PDMS/BaTiO <sub>3</sub>	100	2500	150	5	1.2	32
PDMS/CNT	6	77.8	25.7	3	3.3	12
PDMS/SrBaTiO <sub>3</sub>	90	280	8.5	100	4.4	33
PVDF/3D ZnO	6	17	2.5	—	—	34
Teflon-PDMS/ZIF-67	—	118	1.7	50	0.15	22
Al/PVDF/Cu-PDMS/ITO/PET	—	88	20	4.5	—	20
PDMS/AGs nanowires	20	33.6	4.5	8.6	0.23	21
PDMS/MWCNT	4	110	10	5	0.98	<b>This work</b>

$$Q_{\text{half}} = \frac{I_{\text{max}}}{2\pi f} [-(-1 + 1)] = \frac{2I_{\text{max}}}{2\pi f} = \frac{I_{\text{max}}}{\pi f} \quad (7)$$

For PDMS

$$Q_{\text{full}} = \frac{2I_{\text{max}} \times T}{\pi} = \frac{2 \times 4.5 \times 10^{-6} \times 0.02}{3.14} = 0.05 \mu\text{C}$$

For 0.050 wt% MWCNTs

$$Q_{\text{full}} = \frac{2I_{\text{max}} \times T}{\pi} = \frac{2 \times 10 \times 10^{-6} \times 0.04}{3.14} = 0.25 \mu\text{C}$$

The 0.050 wt% MWCNTs showed the maximum accumulated charge and charge density of 0.25 μC and 637 μC m<sup>-2</sup> in one complete alternating cycle. The overall performance of the proposed device was assessed by calculating the figure of merit (FOM). This parameter, influenced by the surface properties of the materials, was evaluated for both the device (FOM<sub>device</sub>) and the material (FOM<sub>material</sub>). The calculations were carried out for pure PDMS and PDMS incorporating 0.05 wt% MWCNTs using the following expressions (8)–(13).

$$\text{FOM}_{\text{device}} = 0.064 \times \frac{\sigma_{\text{T}}^2 V_{\text{m}}}{\epsilon_0} \quad (8)$$

$$\text{FOM}_{\text{material}} = \frac{\sigma_{\text{T}}^2}{\epsilon_0} \quad (9)$$

$$\eta = \frac{E_{\text{output}}}{E_{\text{input}}} \quad (10)$$

$$E_{\text{output}} = \text{power} \times \text{time} \quad (11)$$

$$E_{\text{input}} = \text{force} \times \text{gap between the two plates}, \quad (12)$$

$$V_{\text{m}} = \omega_{\text{r}} \cdot \frac{X_{\text{max}}}{\pi} \quad (13)$$

where  $\epsilon_0$  represents the permittivity of a vacuum,  $\sigma_{\text{T}}$  is the surface charge density, and  $V_{\text{m}}$  is the velocity of the contact-separation impact motion. In this expression,  $X_{\text{max}} = 6$  mm was the maximum gap between the two materials, and  $\omega_{\text{r}} = 2\pi f$ .<sup>36</sup> The FOM<sub>device</sub> and FOM<sub>material</sub> values of the proposed pure PDMS and 0.05 wt% MWCNTs were 0.97 W m<sup>-2</sup>, 1.7 kJ m<sup>-3</sup>, and 70 W m<sup>-2</sup>, 45 kJ m<sup>-3</sup> and the efficiency was 1.0%, respectively.

## 2.2. Biomechanical energy-harvesting applications

Human body motion, typically characterized by low frequencies, can be effectively harvested by CS-TENGs and stored for

**Fig. 7** Applications of TENG devices. (a) Schematic of a TENG used for charging a stopwatch, (b) demonstration of a capacitor charging using a TENG, (c) architectural design of a TENG integrated into a shoe for wearable applications, and (d) output voltage performance under different motion conditions, including walking, jogging, and running.

later use. To illustrate this capability, common forms of bio-mechanical energy, such as hand tapping, walking, and running, were employed as examples. The circuit configuration is depicted in Fig. 7(a), where the output of the CS-TENG was connected to one terminal of a full-wave rectifier circuit, while the other terminal was left floating. The rectified output was then utilized to operate a stopwatch powered by the TENG. In Fig. 7(b), it can be seen that the rectified output was also connected to various capacitors, ranging from 1.0 to 10.0  $\mu\text{F}$ , for charging purposes. These capacitors can subsequently power electronic devices. A 1  $\mu\text{F}$  capacitor was charged to 4.2 V within 120 s, causing a group of LEDs to illuminate, as shown in figure and Video S1.<sup>†</sup> Furthermore, the TENG device was integrated into a shoe and tested under different human motion conditions, such as walking, jogging, and running.

The device generated output voltages of 5, 10, and 20 V, respectively, for these activities, as shown in Fig. 6(c) and (d).

The TENG device was employed to trigger an action—specifically, toggling an LED, as shown in Fig. 8(a). When subjected to an applied force, the TENG device generated voltage spikes, each comprising a positive voltage peak followed by a negative one. The amplitude of these spikes varied depending on the magnitude of the applied force. To ensure compatibility with the microcontroller's logic level, the voltage spikes were processed through a full-wave rectifier, which converted all the negative voltage peaks into positive ones to produce a uni-directional voltage signal, as illustrated in Fig. 8(b) and (d).

A forward-biased LED was then used to clip the maximum voltage to 2.2 V, protecting the microcontroller from excessive voltage levels. The microcontroller continuously monitored the

**Fig. 8** Further applications of the TENG. (a) Action trigger mechanism illustrated with an LED response, (b) representation of a TENG device along with its circuit schematic, (c) visual depiction of the sensing device setup, and (d) demonstration of the response mechanism based on the applied logic.

rectified and clipped voltage *via* its analog-to-digital converter (ADC). When the input voltage exceeded the threshold of 2.0 V, the microcontroller toggled the state of an external LED connected through a current-limiting resistor. An LED could then be controlled by an HMI system to switch on and off.<sup>37</sup> This configuration enabled reliable detection and response to the force-induced voltage spikes generated by the TENG device. A visual depiction of the sensing device setup is shown in Fig. 8(c) and Video S2.† This demonstration showcased the potential of the TENG as a self-powered sensor in the HMI system.

### 3. Conclusions

To summarise, we developed a composite PDMS-MWCNT-based TENG that demonstrated improved triboelectric characteristics. By integrating 0.025, 0.050, 0.075, and 0.10 wt% of MWCNTs into the PDMS matrix, several different composite PDMS-MWCNT membranes were created. The composition that included 0.050 wt% of MWCNTs demonstrated the most impressive performance among the five TENG samples. It was able to achieve a maximum power density of  $0.97 \text{ W m}^{-2}$ ,  $I_{\text{sc}}$  of  $10.0 \mu\text{A}$ , and  $V_{\text{oc}}$  of 110 V. It was found that the better charge transfer that was made possible by the MWCNTs acting as a conductive filler was responsible for the increased triboelectric output. In addition, the TENG demonstrated remarkable stability, maintaining a consistent performance over 10 000 cycles. The fabricated TENG was integrated with the human body to harvest output voltage signals generated during various human motions, demonstrating its potential for signal-sensing applications under applied forces.

## 4. Materials and methods

### 4.1. Synthesis of the nanocomposite films

The nanocomposite films were fabricated by combining PDMS (Sylgard 184) acquired from Jain Chemicals with MWCNTs with an outer diameter ranging from 20 to 30 nm, procured from Nano Shel, Inc., India.

### 4.2. Synthesis of the pure PDMS film

A PDMS film was developed by combining the elastomer and curing agent in a 1 : 10 weight ratio. After physically combining the components for 10 min, the mixture underwent sonication for 20 min to remove any air bubbles. Subsequently, it was poured into a hollow that had been created on a sheet covered with copper. It was then evenly distributed using a spin coater. The film underwent thermal treatment on a hot plate at a temperature of 100 °C for 2 h and then underwent post-treatment at room temperature for 6 h.

### 4.3. Synthesis of the MWCNT-PDMS composite film

The PDMS-MWCNT membrane was fabricated by dispersing MWCNTs in a chloroform solution. In the process of creating the PDMS-MWCNT composite, MWCNTs were first dissolved in 10 mL of chloroform at a concentration of  $0.5 \text{ mg mL}^{-1}$ .

Following vacuum desiccation, the chloroform was allowed to evaporate at room temperature. Sonication was used for 20 min to volatilize the chloroform. The PDMS base was then mixed with the PDMS curing agent at a weight ratio of 10 : 1. To get rid of any air bubbles, the PDMS mixture was sonicated for a further 20 min. Following that, it was poured into a hollow mould made on a copper-coated sheet and left to cure for 2 h at 100 °C on a hot plate.

### 4.4. Fabrication of the CS-TENG

The fabrication process of the CS-TENG is illustrated in Fig. 8. Initially, a copper-clad sheet with an area of  $16 \text{ cm}^2$  was cleaned using acetone and ethanol to remove any dust particles from its surface. The cleaned sheet was then placed on a spin coater, vented, and rotated at a speed of 200 rpm for 120 s. A prepared MWCNT-PDMS composite solution was carefully dropped onto the surface of the copper-clad sheet. Once the solution was uniformly dispersed across the surface, the sheet was removed from the spin coater and dried on a hot plate at 80 °C for 2 h. After drying, the sample was cut into smaller pieces with an area of  $4 \text{ cm}^2$  as shown in Fig. 9. For CS-TENG operation, two surfaces are required to facilitate contact electrification. Therefore, two materials were selected: the composite film, which served as the negative triboelectric material, and copper, chosen as the positive material based on the triboelectric series. Copper was selected as the electrode material in the PDMS-MAX phase-based TENG, even though it is slightly less negative than aluminium in the triboelectric series. While aluminium could potentially offer higher triboelectric output due to its greater polarity difference with PDMS, copper presents several advantages that make it more suitable for practical applications.<sup>38</sup> For instance, it offers excellent electrical conductivity, better resistance to oxidation, and enhanced chemical stability, which are critical for maintaining consistent performance over time. Additionally, copper provides stronger adhesion to both PDMS and MAX phase materials, improving the mechanical robustness and durability of the device under repeated use. Further, the oxidation potential of copper and aluminium are  $-0.34$  and  $-1.66 \text{ V}$ , respectively, indicating that aluminium has a higher tendency of getting oxidized than copper, which would not be good for the electrode over a long lifetime. These factors make copper a more reliable and efficient choice for flexible and wearable triboelectric nanogenerators. A conductive layer was established by connecting a jumper wire at the interface at the positive and negative triboelectric layers. Finally, the device was connected to a measuring instrument *via* two wire terminals to evaluate its output performance.

### 4.5. Working mechanism of the TENG

The working mechanism of the CS-TENG is illustrated in Fig. 10. In state 1, the triboelectric layers are not in touch, resulting in no transmission of charge across the two electrodes. By the triboelectric effect, charge transfer occurs between one layer and another layer in state 2, provided that an external load is applied to the system. With the removal of the external load, the triboelectric materials begin to separate from one another, which results in a

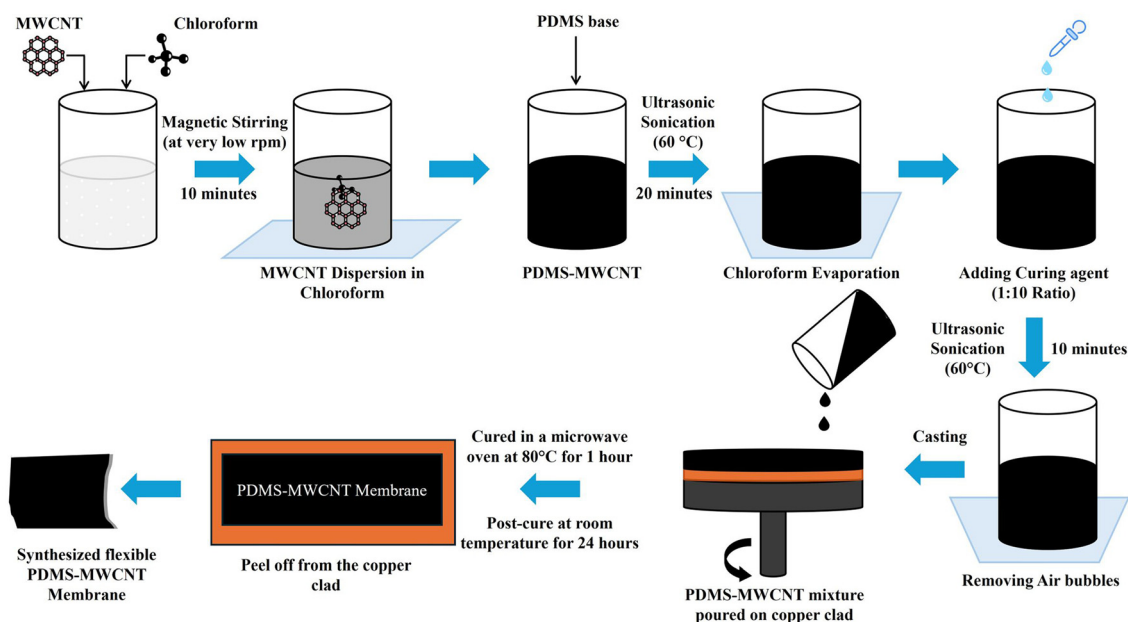

Fig. 9 Fabrication procedure for the flexible PDMS-MWCNT composite membrane.

Fig. 10 Distribution of the transient charge in each tribological layer in a sequential manner, along with the operating principle of the device.

distribution of the electrical equilibrium. Additionally, as both materials begin to separate from one another, the output voltage tends to grow. By restoring the composite polymer to its original form whenever both components are completely separated from one another, we can achieve the highest possible output voltage, as seen in state 4. When we apply the external load once again, the voltage tends to decrease, as shown in state 5. Between the triboelectric layers, this method consistently displays an alternating current (AC) electrical output.<sup>24</sup>

#### 4.6. Characterizations details

The structural properties of the synthesized materials were determined by X-ray diffraction (XRD), utilizing a Rigaku X-ray diffractometer and Cu K $\alpha$  radiation ( $\lambda = 1.54 \text{ \AA}$ ) in the angular range of  $10^\circ$ – $70^\circ$  at a scanning rate of  $3^\circ \text{ min}^{-1}$ . A Raman spec-

trum was produced using a Wi Tech alpha 300R confocal Raman microscope, a laser with a wavelength of 532 nm, an integration time of 10, and a  $100\times$  objective. The PDMS membrane and the PDMS-MWCNT composite membrane were examined using Fourier transform infrared spectroscopy (FTIR). The scanning was carried out with the assistance of a VERTEX 80v instrument (Bruker, Germany) that was fitted with a horizontal attenuated total reflectance (ATR) assessor. The scanning was carried out at room temperature in the wave-number range of  $3500$ – $300 \text{ cm}^{-1}$ .

#### Data availability

The data that support the findings of this study are available within the article and its ESI.†

## Conflicts of interest

The authors have no conflicts to disclose.

## Acknowledgements

The authors express their gratitude to the National Research Facility and Central Research Facility at the Indian Institute of Technology Delhi for the XRD measurement. This research was funded by SERB-DST, CRG (CRG/2023/006778), FIST (SR/FST/ET-I/2020/628), SEED Grant, FIRP, and MFIRP grant from IIT Delhi. The experiment was conducted in the Advanced Electronics Materials and Systems (AEMS) laboratory, Department of Materials Science and Engineering, IIT Delhi.
