# Reductive cleavage of C=C bonds as a new strategy for turn-on dual fluorescence in effective sensing of H<sub>2</sub>S†

Chunfei Wang,<sup>a</sup> Xiaoxiang Cheng,<sup>a</sup> Jingyun Tan,<sup>a</sup> Zhaoyang Ding,<sup>a</sup> Wenjing Wang,<sup>b</sup> Daqiang Yuan,<sup>b</sup> Gang Li,<sup>a</sup> Hongjie Zhang<sup>\*a</sup> and Xuanjun Zhang<sup>\*a</sup>

Reductive cleavage of alkenes is rarely reported in synthetic chemistry. Here we report a unique H<sub>2</sub>S-mediated reductive cleavage of C=C bonds under mild conditions, which is a successful new strategy for the design of probes for effective sensing of H<sub>2</sub>S with turn-on dual-color fluorescence. A short series of phenothiazine ethylidene malononitrile derivatives were shown to react with H<sub>2</sub>S, via reductive cleavage of C=C bonds with intramolecular cyclization reactions to form thiophene rings. Enlightened by this new reaction mechanism, four effective probes with turn-off to turn-on fluorescence switches were successfully applied for sensing H<sub>2</sub>S, an important gaseous signalling molecule in living systems, among which PTZ-P4 exhibited two fluorescent colors after reductive cleavage. The dual-color probe was applied for imaging endogenous H<sub>2</sub>S and showed distinct differences in brightness in living *C. elegans* for wild type N2, *glp-1* (e2144) mutants (higher levels of endogenous H<sub>2</sub>S), and *cth-1* (ok3319) mutants (lower levels of endogenous H<sub>2</sub>S). The discovery of H<sub>2</sub>S-mediated reductive cleavage of C=C bonds is expected to be valuable for chemical synthesis, theoretical studies, and the design of new fluorescent H<sub>2</sub>S probes.

## Introduction

The discovery of novel reactivities with carbon-carbon double bonds (C=C) is not only useful for chemical synthesis and theoretical studies, but is also important for applications in biology, because C=C bonds are abundant in nature. As we all know, C=C bonds are fundamental structures of alkenes, where the C=C  $\pi$  bond is localized above and below the C-C  $\sigma$  bond wherein  $\pi$  electrons are relatively far away from the nuclei and are loosely bound, so that they can be easily attacked to construct a new bond.<sup>1,2</sup> Indeed, addition reactions are one of the common reactions of C=C bonds, such as reactions with HX (X = Cl, Br, I, OH, SH, RS, etc.) as described in Scheme 1a.<sup>3</sup> Additionally, C=C bonds can also be cleaved by oxidation as in the typical ozonolysis of alkenes (Scheme 1b).<sup>4</sup> However, because of their unique structure, reductive cleavage of alkenes (C<sub>sp</sub><sup>2</sup>-C<sub>sp</sub><sup>2</sup>) has rarely been reported so far.

In particular, the cleavage of C=C bonds in styrenes has been activated by a hard Lewis acid and ethanethiol.<sup>5,6</sup> In

addition, Shi and coworkers reported reductive cleavage of C<sub>sp</sub><sup>2</sup>-C<sub>sp</sub><sup>3</sup> bonds using rhodium based catalysis.<sup>7</sup> In 2014, Bogdanov *et al.* reported that C=C bonds in 1,10-disubstituted isoindigos could be reductively cleaved by aqueous hydrazine hydrate.<sup>8</sup> In this work, we discovered an interesting H<sub>2</sub>S-mediated reductive cleavage of C=C bonds under mild conditions.

As is well known, H<sub>2</sub>S with sulfur at the lowest valence is an excellent reductant and nucleophile, found predominantly as HS<sup>-</sup> at physiological pH and therefore displaying higher nucleophilicity compared with many other thiols in cells. Consequently, addition reactions have been a commonly used strategy for developing fluorescent H<sub>2</sub>S probes in recent years. Highlighting the popularity and influence of this reaction mechanism, many fluorescent probes were well designed with rapid and specific responses to H<sub>2</sub>S by disrupting the conjugated  $\pi$ -system of C=C bonds with addition reactions.<sup>9-13</sup> In addition, aryl nitro groups could be cleaved by thiolysis, triggering the fluorescence turn-on for the detection of H<sub>2</sub>S or H<sub>n</sub>S<sub>n</sub>.<sup>14-17</sup> In the current work, we report our finding of H<sub>2</sub>S-mediated reductive cleavage of C=C bonds under mild conditions (Scheme 1c), anticipated to be a new strategy for devising fluorescent H<sub>2</sub>S probes. Concomitant with this has been the development of a dual-color fluorescent H<sub>2</sub>S probe, which was successfully applied to monitor endogenous H<sub>2</sub>S *in vivo*.

surprising that the C17–C18 double bond in **PTZ-P1** was reductively cleaved and the pyridine moiety was cut off from the main structure, which was consistent with the NMR and MS analysis (Fig. 2a and b).

Three more derivatives, **PTZ-P2**, **PTZ-P3**, and **PTZ-P4**, were then designed and synthesized. For **PTZ-P3**, **BODIPY** was introduced for its good photostability, narrow emission, and high fluorescence quantum yield. In **PTZ-P4**, a red emitting

## Results and discussion

### Design, synthesis and characterizations

Phenothiazine (PTZ), having a non-planar butterfly conformation, provides strong fluorescence, and has been used as an electron donor in photoelectric materials with a variety of applications.<sup>18–22</sup> We found that phenothiazine ethylidene malononitrile derivatives, **PTZ-P1**, **PTZ-P2**, **PTZ-P3** and **PTZ-P4**, could effectively react with H<sub>2</sub>S *via* reductive cleavage of C=C bonds to yield a new fluorescent compound **PTZCNSF**.

Firstly, we use **PTZ-P1** as an example to discuss this novel reaction. PTZ is a strong electron donor whereas the dicyano group is a strong electron acceptor. The strong intramolecular charge transfer (ICT) in **PTZ-P1** gave rise to fluorescence quenching. Upon reacting with H<sub>2</sub>S, **PTZ-P1** exhibited turn-on fluorescence with high selectivity and sensitivity.

To dissect the reaction mechanism, **PTZ-P1** was used to react with NaHS and the green fluorescent product, **PTZCNSF**, was successfully isolated. The NMR results of **PTZCNSF** (Fig. S25 and S26†) demonstrated the disappearance of the pyridine moiety and single crystal X-ray analysis was further used to confirm the structure. Single crystals of **PTZ-P1** and **PTZCNSF** for X-ray diffraction were obtained by slow evaporation of dichloromethane solutions, and ORTEP drawings are depicted in Fig. 1. During the transformation from **PTZ-P1** to **PTZCNSF**, C13, C14, C16 and C17 were connected by S2 from H<sub>2</sub>S *via* an intramolecular cyclization reaction to yield **PTZCNSF**. It is

**Fig. 2** MS data of PTZ-P1, PTZCNSF, and the red emitting products of PTZ-P4 after the reaction with H<sub>2</sub>S.

fluorophore (**BOBPY**) was chosen to conjugate with phenothiazine ethylidene malononitrile. **BOBPY** and derivatives were first developed by Jiao and coworkers,<sup>23</sup> and they are a kind of N<sub>2</sub>O-type benzopyrromethene boron complex, wherein axial positions are substituted by corresponding boronic acids. We chose **BOBPY** here because of its excellent stability and high fluorescence quantum yield in different media. We hypothesized that both green and red emitting fluorophores will be released after reductive cleavage, and these could be used as dual-color fluorescent probes for sensing H<sub>2</sub>S.

Detailed synthetic procedures are elucidated in the ESI.† Products and intermediates were fully characterized using <sup>1</sup>H NMR, <sup>13</sup>C NMR, HRMS and MALDI-TOF spectra (Fig. S8–S24, S27–S29†). All four derivatives could effectively react with H<sub>2</sub>S *via* reductive cleavage of C=C bonds to produce **PTZCNSF**. However, pure single samples of the other part were difficult to isolate, because of the high reactivity of the –CH<sub>2</sub> moiety after reductive cleavage. Fortunately, the MALDI-TOF data of **PTZ-P4** revealed that the –CH<sub>2</sub> moiety could form R–CH<sub>3</sub> monomers and dimers (Fig. 2c) under these reductive conditions. Although the exact reaction pathway is still under investigation, MS, NMR, and single-crystal X-ray analysis undoubtedly confirmed this H<sub>2</sub>S-mediated reductive cleavage of C=C bonds.

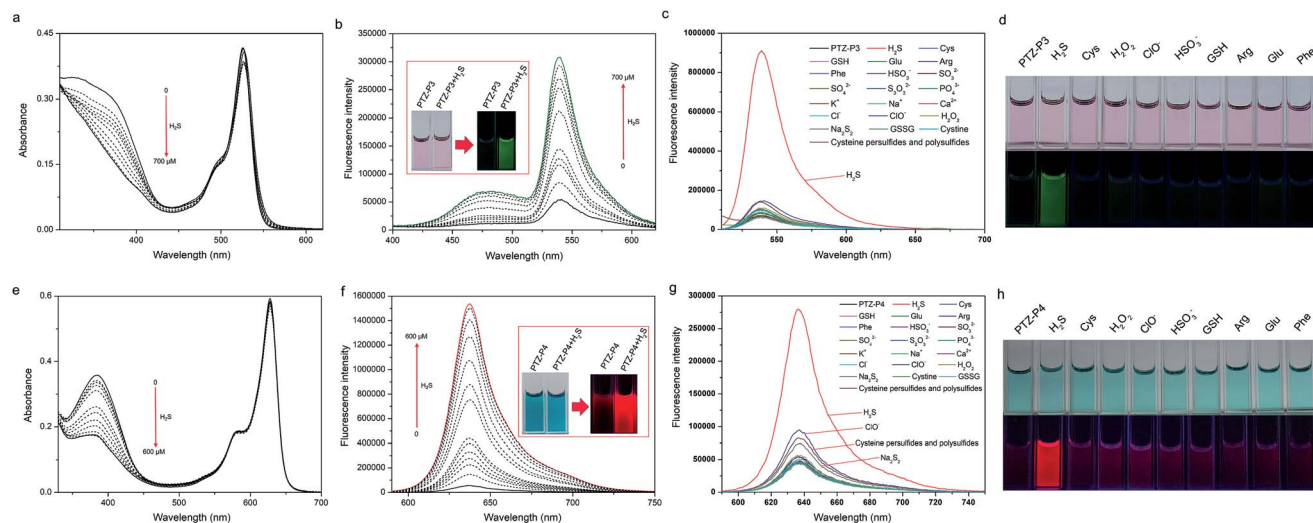

### Absorption and fluorescence response of probes to H<sub>2</sub>S

With these probes in hand, their responses to H<sub>2</sub>S were studied. Initially, the absorption spectra of **PTZ-P1** upon addition of H<sub>2</sub>S were assessed in PBS buffer (pH = 7.4)/DMSO (1/2, 2% v/v PEG 400) using aqueous NaHS as the H<sub>2</sub>S source. As depicted in

Fig. S5a†, **PTZ-P1** showed a main absorption peak at 330 nm along with a weak-intensity ICT band at around 500 nm. The absorption intensity decreased upon the gradual addition of H<sub>2</sub>S (0–800 μM). However, **PTZ-P1** showed a turn-on fluorescence response at 488 nm with a 25-fold enhancement (Fig. S5b†). The absorption and fluorescence of **PTZ-P2** responding to H<sub>2</sub>S were similar to those of **PTZ-P1** (Fig. S6†). However, the increase of the fluorescence intensity was lower (only a 5-fold increase), which may be attributed to the stronger electron withdrawing strength of the dipyrindyl moiety compared with the pyridyl group.

Subsequently, spectra titration experiments were performed to further investigate the response of **PTZ-P3** towards H<sub>2</sub>S. The characteristic absorption peaks at 330 nm decreased upon gradual addition of H<sub>2</sub>S (0–700 μM), whereas the peaks at 525 nm did not change much (Fig. 3a). The decrease of the absorption peak at 330 nm revealed the reductive cleavage of **PTZ-P3** induced by H<sub>2</sub>S, and was consistent with those of **PTZ-P1** and **PTZ-P2**. As shown in Fig. 3b, very weak emission of **PTZ-P3** (10 μM) was displayed in PBS buffer (pH = 7.4)/DMSO (1/2, 2% v/v PEG 400) without H<sub>2</sub>S because of the strong ICT, but the emissions at 480 nm and 540 nm were both remarkably increased upon gradual addition of H<sub>2</sub>S (0–700 μM). The enhanced emission at 480 nm was caused by **PTZCNSF** after reductive cleavage, which was consistent with those of **PTZ-P1** and **PTZ-P2**. However, heightening emission at 540 nm was related to the **BODIPY** moiety being released from **PTZ-P3**.

In the presence of H<sub>2</sub>S, the ethylenic bond was reductively cleaved, so that optical properties of **PTZ-P4** were observed both

**Fig. 3** (a and b) Absorption and fluorescence spectra of **PTZ-P3** (10 μM) in PBS buffer (pH = 7.4)/DMSO (1/2, 2% v/v PEG 400) with the addition of H<sub>2</sub>S (0–700 μM),  $\lambda_{\text{ex}}$  = 330 nm. Inset in (b): photoimages of **PTZ-P3** with and without H<sub>2</sub>S under daylight (left) and an ultraviolet lamp (365 nm; right). (c) The fluorescence spectra of **PTZ-P3** (10 μM) in the presence of H<sub>2</sub>S (0.5 mM), Na<sub>2</sub>S<sub>2</sub> (0.2 mM), cysteine persulfides and polysulfides (0.2 mM) and other analytes (0.5 mM) in PBS buffer (pH = 7.4)/DMSO (1/2, 2% v/v PEG 400), excitation: 500 nm. (d) Photoimages of **PTZ-P3** with H<sub>2</sub>S (0.5 mM) and other analytes under daylight (above) and an ultraviolet lamp (365 nm, below). (e and f) Absorption and fluorescence spectra of **PTZ-P4** (10 μM) in PBS buffer (pH = 7.4)/DMSO (1/2, 2% v/v PEG 400) with the addition of H<sub>2</sub>S (0–600 μM),  $\lambda_{\text{ex}}$  = 580 nm. Inset in (f): photoimages of **PTZ-P4** with and without H<sub>2</sub>S under daylight (left) and an ultraviolet lamp (365 nm; right). (g) The fluorescence spectra of **PTZ-P4** (10 μM) in the presence of H<sub>2</sub>S (0.5 mM), Na<sub>2</sub>S<sub>2</sub> (0.2 mM), cysteine persulfides and polysulfides (0.2 mM) and other analytes (0.5 mM) in PBS buffer (pH = 7.4)/DMSO (1/2, 2% v/v PEG 400), excitation: 580 nm. (h) Photoimages of **PTZ-P4** with H<sub>2</sub>S (0.5 mM) and other analytes under daylight (above) and an ultraviolet lamp (365 nm, below).

from **PTZCNSF** and **BOBPY**. Bearing this point in mind, the responses of absorption and fluorescence of **PTZ-P4** to  $\text{H}_2\text{S}$  were studied by gradual addition of NaHS solution into a PBS buffer (pH = 7.4)/DMSO (1/2, 2% v/v PEG 400) solution containing 10  $\mu\text{M}$  probe. As illustrated in Fig. 3e, the absorption peaks of **PTZ-P4** at 384 nm were exhibited as decreasing, while the absorption peaks at 628 nm displayed almost no change after gradually adding  $\text{H}_2\text{S}$  (0–600  $\mu\text{M}$ ). As expected, the fluorescence spectra were consistent with **PTZ-P1** in the green region, but the red fluorescence was so strong that the weak green fluorescence was covered with the insignificant ratio-metric change. As shown in Fig. 3f, the emission intensity at 638 nm ( $\lambda_{\text{ex}}$  = 580 nm) increased about 30-fold for **PTZ-P4** upon addition of 600  $\mu\text{M}$   $\text{H}_2\text{S}$ .

### Selectivity of **PTZ-P3** and **PTZ-P4** to $\text{H}_2\text{S}$

The selectivity of the **PTZ-P3** and **PTZ-P4** towards  $\text{H}_2\text{S}$  was further identified. **PTZ-P3** and **PTZ-P4** (10  $\mu\text{M}$ ) were both treated respectively with various biologically relevant analytes in PBS buffer (pH = 7.4)/DMSO (1 : 2, 2% v/v PEG 400) for 10 min. As shown in Fig. 3c, d, g and h, the turn-on fluorescent responses of **PTZ-P3** and **PTZ-P4** are highly selective for  $\text{H}_2\text{S}$  versus biologically relevant thiols, reactive oxygen species (ROS) such as  $\text{H}_2\text{O}_2$  and  $\text{ClO}^-$ , ions including  $\text{K}^+$ ,  $\text{Na}^+$ ,  $\text{Ca}^{2+}$ ,  $\text{HSO}_3^-$ ,  $\text{SO}_3^{2-}$ ,  $\text{SO}_4^{2-}$  and  $\text{S}_2\text{O}_3^{2-}$ , and so on. Cysteine, cystine, glutathione,  $\text{Na}_2\text{S}_2$ , and cysteine persulfides and polysulfides<sup>24</sup> induced very little increase of fluorescence intensity. Therefore, both **PTZ-P3** and **PTZ-P4** showed high selectivity for  $\text{H}_2\text{S}$ .

### Imaging exogenous $\text{H}_2\text{S}$ in living cells

After developing these probes based on the novel reductive cleavage of  $\text{C}=\text{C}$  bonds, we explored the applications of **PTZ-P4** in monitoring  $\text{H}_2\text{S}$  under physiological conditions. The cytotoxicity of **PTZ-P4** was evaluated in HeLa cells using a MTT assay.

As described in Fig. S7†, **PTZ-P4** exhibited relatively low toxicity towards HeLa cells with good viability. Putting **PTZ-P4** into practice, exogenous  $\text{H}_2\text{S}$  was detected in living HeLa cells. Firstly, HeLa cells were exposed to 20  $\mu\text{M}$  **PTZ-P4** for 5 h, then NaHS solution was used as the exogenous  $\text{H}_2\text{S}$  source at 100  $\mu\text{M}$ , incubating with cells for another 3 h. Compared with cells treated with only **PTZ-P4**, there was obvious green and red fluorescence in cells treated with both  $\text{H}_2\text{S}$  and **PTZ-P4** (Fig. 4).

### Imaging endogenous $\text{H}_2\text{S}$ in living *C. elegans*

Endogenous  $\text{H}_2\text{S}$  mainly originates from sulfur-containing amino acids metabolized by at least three enzymes: cystathionine  $\beta$ -synthase (CBS), cystathionine  $\gamma$ -lyase (CSE) and 3-mercaptopyruvate sulfur transferase (3-MST).<sup>25</sup> *C. elegans* is an excellent *in vivo* model system for monitoring physiological  $\text{H}_2\text{S}$  with clear molecular mechanisms of  $\text{H}_2\text{S}$  action.<sup>26,27</sup> Specifically, it has been shown that the germline-deficient *glp-1* (e2144) mutants displayed increasing production of endogenous  $\text{H}_2\text{S}$ , while the deletion mutation in *cth-1*, the gene encoding the  $\text{H}_2\text{S}$  synthesizing enzyme cystathionine  $\gamma$ -lyase, resulted in down-regulated  $\text{H}_2\text{S}$  levels.<sup>27–30</sup> To further understand the features of

Fig. 4 Confocal images of exogenous  $\text{H}_2\text{S}$  in HeLa cells without (top) and with (bottom) 100  $\mu\text{M}$   $\text{H}_2\text{S}$  in the presence of 20  $\mu\text{M}$  **PTZ-P4**. Scale bar: 20  $\mu\text{m}$ .

**PTZ-P4**, *in vivo* imaging was employed to visualize endogenous  $\text{H}_2\text{S}$  in *C. elegans*. Concentrations of **PTZ-P4** and time periods used for feeding were titrated to ensure enough **PTZ-P4** absorption and metabolism without significant biotoxicity (data not shown). In living *C. elegans*, **PTZ-P4** should be absorbed, distributed, metabolized and excreted, and so 200  $\mu\text{M}$  **PTZ-P4** was used to make sure that there was enough **PTZ-P4** in *C. elegans* for *in vivo* imaging. As a representative example shown in Fig. 5a, both green and red fluorescence were observed in wild-type N2 worms after being fed with 200  $\mu\text{M}$  **PTZ-P4** for 48 h. Additionally,  $\text{H}_2\text{S}$  was mainly accumulated in intestinal cells, predominantly in the cytoplasm, and in apical membranes as well (Fig. 5a and data not shown).

Fig. 5 (a) Confocal images captured the  $\text{H}_2\text{S}$  distribution in wild type N2 with 200  $\mu\text{M}$  **PTZ-P4**; the scale bar was 25  $\mu\text{m}$ . (b) Fluorescence images of endogenous  $\text{H}_2\text{S}$  in wild type N2, germline-deficient *glp-1* (e2144) mutants and *cth-1* (ok3319) mutants incubated with 200  $\mu\text{M}$  **PTZ-P4**. Normal, elevated and reduced endogenous  $\text{H}_2\text{S}$  levels are shown from left to right; the scale bar was 200  $\mu\text{m}$ . (c) Fluorescence intensities were measured along a line crossing the anterior of the intestine.

Consistent with changes of H<sub>2</sub>S levels in different strains, the red fluorescence intensity of *glp-1* (*e2144*) mutants was obviously stronger than that in wild-type N2 worms, while *cth-1* (*ok3319*) mutants exhibited notably weaker red fluorescence compared with wild-type N2 worms (Fig. 5b and c). This result suggested that red fluorescence signals could be clearly captured with significant changes and successfully reflected different H<sub>2</sub>S levels under different physiological conditions. Of note, differences in green fluorescence among different strains were also detected, albeit to a less appreciable level (Fig. 5c), due to the weak absorbance of **PTZCNSF** at 405 nm (the excitation wavelength of the fluorescence microscope). Altogether, these results provided compelling evidence that **PTZ-P4** is highly sensitive and selective with dual fluorescent colors to detect endogenous H<sub>2</sub>S in living systems and can be used as a potential probe for *in vivo* imaging of endogenous H<sub>2</sub>S.

A significant bottleneck in detecting H<sub>2</sub>S is the effective imaging of endogenous H<sub>2</sub>S *in vivo*, a problem that restrains the biological applications. In the current study, the dual-color fluorescent probe **PTZ-P4** showed high selectivity for H<sub>2</sub>S versus cysteine or glutathione. It also demonstrated a good response concurrently with the application in different strains of *C. elegans*, showing distinct differences in brightness for wild type N2, *glp-1* (*e2144*) and *cth-1* (*ok3319*) mutants.

## Conclusions

In summary, we have discovered H<sub>2</sub>S-mediated reductive cleavage of C=C bonds under mild conditions, which was successful as a new strategy to design fluorescent probes for effective detecting of H<sub>2</sub>S. Of these probes, **PTZ-P4** displayed dual-color turn-on fluorescence upon *in vivo* sensing of endogenous H<sub>2</sub>S in different strains of *C. elegans*, showing distinct differences in brightness for wild type N2, *glp-1* (*e2144*) and *cth-1* (*ok3319*) mutants. As far as we know, this is the first report that H<sub>2</sub>S can reductively cleave C=C bonds under mild conditions. As C=C bonds are actively involved in various organic reactions, the discovery of this reductive cleavage of C=C is anticipated to be valuable not only for the development of C=C bonds in synthetic chemistry and theoretical studies, but also for the design of new fluorescent H<sub>2</sub>S probes for bioimaging and sensing applications.
