We developed supramolecular hyaluronate (HA) hydrogels to encapsulate genetically engineered mesenchymal stem cells (MSCs) for the treatment of limb ischemia. *In vivo* angiogenic factors could be produced stably by the bioengineered MSCs (BMSCs) within the supramolecular hydrogels showing effective vascular repair and enhanced blood perfusion.

Clinical limb ischemia (CLI) is the severe manifestation of peripheral arterial disease, which is one of the most common diseases in the population over 70 years old, up to 20%.<sup>1</sup> Especially for 30% of the patients who suffer from CLI, amputation is the only remaining method, because the conventional treatments such as medication, endovascular therapy and arterial surgery are not very helpful.<sup>2</sup> Revascularization is necessary to restore the damaged tissue without amputation. Revascularization is a sequential and sophisticated process related to various signaling molecules participating in matrix reconstruction, migration and assembly.<sup>3</sup> To accelerate the revascularization in ischemic areas, therapeutic treatment aims to deliver concentrated angiogenic factors locally, such as vascular endothelial growth factor A (VEGF-A) and hepatocyte growth factor (HGF). VEGF-A is a well-known angiogenic factor, participating in the early stage of vessel sprouting. HGF is also one of the representative angiogenic factors. HGF is involved in mitogenesis, migration of epithelial cells, as well as their 3-dimensional organization and generation of new blood capillaries.<sup>4</sup> Neovascularization is known to be synergistically promoted by the combined delivery of HGF and VEGF-A, because their signaling pathways are co-regulated during cellular migration and endothelial morphogenesis.<sup>5</sup>

With the progress of tissue engineering technology, therapeutic neovascularization has been investigated with 3 different strategies for the efficient angiogenic factor delivery.<sup>6</sup> First, angiogenic factors have been directly delivered to contribute to the formation of blood vessels. However, there have been few clinical trials for the direct protein delivery, since their activities cannot be maintained for a sufficient time to regenerate blood vessels.<sup>6</sup> Second, gene therapy has been investigated for the manipulation of host chromosomes by gene delivery with viral or non-viral vectors including adeno-associated virus, lenti-virus and synthetic polymer vesicles.<sup>7</sup> This can raise the angiogenic protein concentration efficiently, but the relevant clinical applications have been limited for limb ischemic diseases.<sup>8</sup> As is well known, there is a considerable risk of an adverse immune response and the overexpression of certain angiogenic factors causing a carcinogenic environment.<sup>7,9</sup>

Lastly, cell therapy has been performed using stem/progenitor cells which can differentiate into vasculature or secrete angiogenic factors.<sup>10</sup> Cell therapy has attracted a great attention defining individual stem/progenitor cells involved in the revascularization processes.<sup>11</sup> Although a few examples with substantial improvement have been reported for the clinical trial of cell therapy,<sup>12</sup> rapid clearance and low viability are significant challenges for the success of cell therapy.

Recently, therapeutic cells are genetically modified for the controlled delivery of angiogenic factors to overcome both the low efficiency of direct protein delivery and the risk of viral-mediated gene delivery. However, rapid clearance and low survival rate of therapeutic cells are still technical hurdles for further development. Diverse studies have been actively conducted to develop various scaffolds to increase the cell survival rate and prevent the rapid clearance of therapeutic cells.<sup>13</sup> As an artificial extracellular matrix

(ECM), hydrogels have been developed to support cells providing a biocompatible environment similar with living tissues in the body.

In this work, we hypothesized that the co-delivery of VEGF-A and HGF released by bioengineered mesenchymal stem cells (BMSCs) might be one of the best approaches for neo-vascularization in ischemic diseases. BMSCs might maintain high expression levels of HGF and VEGF-A within the artificial ECM of hydrogels. A variety of supramolecular hydrogels have been developed using a strong host-guest combination of cucurbituril.<sup>14,15</sup> We previously designed a novel system for long-term and safe delivery of therapeutic proteins by the BMSCs encapsulated in supramolecular hyaluronate (HA) hydrogels.<sup>16,17</sup> Supramolecular HA hydrogels can localize and protect genetically modified MSCs from the host immune systems.<sup>18</sup> In addition, supramolecular hydrogels can be injected without toxic chemical reaction due to the fast crosslinking by the strong host-guest interaction between cucurbit[6]uril (CB[6]) and diaminoethane (DAH) attached to the HA backbone.<sup>15</sup> We assessed the therapeutic efficacy of BMSCs releasing both HGF and VEGF-A in supramolecular hydrogels by laser Doppler imaging (LDI).

To achieve the high crosslinking density and facile synthesis, we carried out mono-functionalization of CB[6], which is a big challenge for various biomedical applications<sup>19,20</sup> (Fig. 1A). Despite the great effort to introduce functional moieties on CB[6],<sup>21</sup> mono-amination of CB[6] is still difficult and complicated.<sup>22,23</sup> We previously reported the method to synthesize CB[6]-HA derivative *via* Michael addition between thiol (SH) modified HA and mono-allyloxy CB[6]. However, there were unreacted thiol groups on HA backbone, resulting in self-crosslinking by disulfide bonding.<sup>24,25</sup> Thus, direct functionalization of CB[6] was needed to avoid side-reaction by the reactive SH group.

First, mono-allyloxy CB[6] was synthesized as previously reported elsewhere.<sup>24,25</sup> To introduce amine groups to mono-allyloxy CB[6], cysteamine was conjugated in the presence of reducing tris(2-carboxyethyl)phosphine (TCEP) and potassium persulfate ( $K_2S_2O_8$ ) as an initiator. The product, mono-aminated CB[6] (mCB[6]) was purified by washing with methanol and acetone sequentially.

In this reaction, TCEP was essential to prevent the formation of the inclusion between mCB[6] and cysteamine. Since cysteamine, a disulfide form of cysteamine, interacts more strongly with the guest-molecule of CB[6] than DAH, CB[6] cannot make the host-guest interaction with DAH for the inclusion formation. After reaction at 70 °C for 24 h, we could confirm mCB[6] was successfully synthesized and the inclusion of cysteamine in mCB[6] was inhibited in the presence of TCEP (Fig. 2A and S1†). The <sup>1</sup>H NMR spectrum showed the characteristic peaks of amine-arms ( $-OCH_2CH_2CH_2-S-CH_2CH_2-NH_2$ ) at  $\delta$  3.1, 2.77, 2.63, 2.22 (Fig. 2A).

Despite the presence of mono-, di-amine and tri-functionalized CB[6] detected in MALDI-TOF MS spectroscopy (Fig. S1†), the majority of the compounds was found to be mono-amine functionalized CB[6], as shown by <sup>1</sup>H NMR (Fig. 2A). Then, we synthesized mCB[6]-HA conjugate by using

Fig. 1 Schematic illustration for (A) sequential synthesis of mCB[6]-HA using mono-amine CB[6] and the preparation of mCB[6]/DAH hydrogels, and (B) *in vivo* tests using BMSCs with the analysis by LDI to investigate ischemic limb reperfusion. Black arrows indicate the ligation point for hind limb surgery.

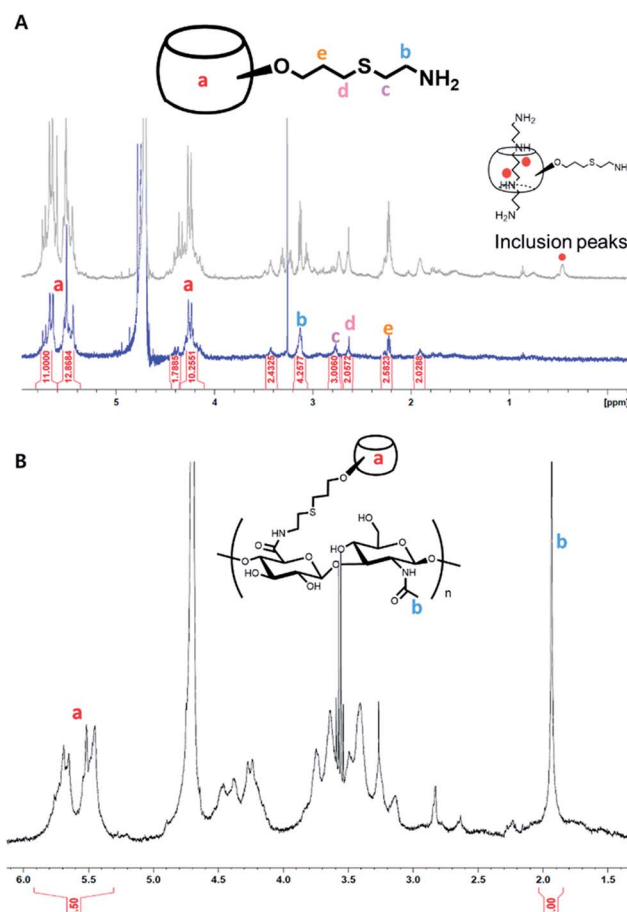

Fig. 2 <sup>1</sup>H NMR analysis for (A) mCB[6], the formation of its inclusion with spermine, and (B) mCB[6]-HA.

the simple EDC chemistry. There was no unreacted group in the final product. Moreover, the substitution rate was incredibly enhanced up to 28% (Fig. 2B). DAH-HA conjugates, a counterpart to mCB[6]-HA, were synthesized and characterized as we described elsewhere.<sup>26</sup> According to the MTT assay (Fig. S2†), the hydrogel precursors of mCB[6]-HA and DAH-HA showed little cytotoxicity at the synthetic concentrations of the hydrogel below 3 wt/v%.

The simple mixing of mCB[6]-HA and DAH-HA resulted in the rapid formation of mCB[6]/DAH-HA hydrogels within 30 s. We have synthesized hydrogels using mCB[6]-HA with a substitution ratio of 7.1% and 21.5%, and confirmed *in vitro* degradation with and without hyaluronidase for 2 weeks (Fig. S3†). As a result, the highly substituted hydrogel (21.5%) degraded by *ca.* 40% for 2 weeks, whereas the low substituted hydrogel (7.1%) was decomposed by *ca.* 70% in the presence of hyaluronidase. The both groups showed little degradation (less than 10%) in the absence of hyaluronidase. In our previous study,<sup>24</sup> because 7% substituted hydrogels degraded slowly in mice for up to 3 months, the 21.5% substituted mCB[6]/DAH-HA hydrogels will remain for more than 3 months.

We used human-derived umbilical cord MSCs, which were kindly provided from Genexine Co. after genetic modification to express angiogenic factors such as HGF and VEGF-A using adenoviral vectors (Fig. 3A). MSCs expressing VEGF-A (BMSCs/VEGF-A) and/or HGF (BMSCs/HGF) were added to the mCB[6]-HA precursor solutions, and then mixed with the DAH-HA precursor solution. The self-assembly of CB[6] and DAH resulted in the immediate hydrogel formation encapsulating BMSCs homogeneously (Fig. 1B). To confirm *in vitro* gene expression of BMSCs with and without the mCB[6]/DAH-HA hydrogels,

BMSC/VEGF-A and BMSC/HGF were cultured in the hydrogel and the expression level of VEGF-A and HGF was analysed by ELISA for 15 days (Fig. 3B and C). As compared with the control group, the expression of VEGF-A and HGF was not so much different for the first and fourth days, but the difference became significant after a week. At day 15, while the expression level of the control group was reduced to less than one third, that of the hydrogel group was maintained at the same level with the initial level.

The animal model of hind limb ischemia was prepared by excision and ligation of superficial femoral artery using 6 to 8 week old BALB/c mice anesthetized with 5% isoflurane (Fig. 1B). After 24 h post-surgery, we subcutaneously injected various samples of only medium (G1),  $5 \times 10^5$  BMSCs/HGF in 100  $\mu$ L of medium (G2), the precursor solutions of matrixen (G3) and mCB[6]/DAH-HA hydrogels (G4). The blood perfusion of the ligated and the control limb was measured and compared by laser Doppler imaging (LDI; Perimed, North Royalton, Ohio) at the predetermined days (day 0, 2, 10 and 24) post-therapy. The

(B) VEGF-A expression levels and (C) HGF expression levels of BMSCs ( $1 \times 10^5$  cells per mL) without and with the mCB[6]/DAH-HA hydrogels on PET membrane transwell inserts (mesh size = 8  $\mu$ m) for specified periods over 2 weeks (mean  $\pm$  SD,  $n = 3$ ,  $*P < 0.0001$ ).

Fig. 4 Laser Doppler imaging (LDI) analysis for the blood reperfusion of BALB/c ischemic limb model mice after injection of BMSCs/HGF in various carriers. (A) Representative LDI images for peripheral blood flow in groups of mice that received media only (G1), BMSC/HGF in media (G2), in matrixen (G3), and in CB[6]/DAH-HA hydrogel (G4) at day 0, 2, 10, 18 and 24. The color-coded image shows the blood flow distribution. The low or no perfusion is shown in blue and the highest perfusion is shown in red. (B) The quantitative analysis of blood flow in hind limbs expressed as the perfusion ratio of ischemic hind limb to the untreated opposite limb ( $n = 5$ ,  $**P < 0.01$  vs. the control of G1). (C) The number of animals categorized in 3 groups as fully recovered, necrotized and amputated limbs at day 24 post-injection.

group treated with BMSCs/HGF encapsulated in mCB[6]/DAH-HA hydrogels showed higher blood perfusion than other groups (Fig. 4A and B). Most of the limbs were amputated in the control group, but only one limb was necrotized in the group of eMSCs/HGF within mCB[6]/DAH-HA hydrogels (Fig. 4C).

Based on these results, we assessed the combination effect of HGF and VEGF-A for ischemic limb reperfusion after subcutaneous injection of intact MSCs (G1), BMSCs/VEGF-A (G2), BMSCs/HGF (G3), and BMSCs/VEGF-A + HGF (G4) mixed with 100  $\mu$ L of the precursor solution of mCB[6]/DAH-HA, respectively. The total population of cells in the hydrogels was  $5 \times 10^5$  per heads. As shown in Fig. 5, VEGF-A and HGF produced by BMSCs helped the recovery of blood perfusion in the ischemic mice. The blood perfusion after treatment with BMSCs/VEGF-A or BMSCs/HGF was recovered more significantly than that of the intact MSCs. The best therapeutic effect was observed in the combination group of BMSCs/VEGF-A + HGF (Fig. 5A and B). After 28 days post-injection, all the limbs were fully recovered in every mouse except one mouse with gangrenous toe (Fig. 5C).

All animal experiments were performed in accordance with the National Institutes of Health Guide for the Care and Use of Experimental Animals and approved by the Institutional Animal Care and Use Committee of the Pohang University of Science and Technology.

The biological half-life of VEGF-A and HGF in the body is less than 50 min and 3 min, respectively.<sup>27</sup> Despite the short half-life, the massive administration of VEGF-A can cause the catastrophic blood vessel formation at the undesirable site. In addition, c-Met, the receptor of HGF, is implicated in the oncogenesis, which can be activated by the overexpressed HGF.<sup>28</sup> Thus, it is crucial to deliver an adequate level of angiogenic factors consistently for the angiogenic therapy. Our BMSCs/VEGF-A + HGF encapsulated in CB[6]/DAH-HA hydrogels might help to maintain the concentration of angiogenic factors continuously for the treatment of ischemia.

## Conclusions

We developed a new ischemic therapy system to deliver angiogenic factors for long-term neovascularization using HGF and VEGF-A expressing BMSCs encapsulated in supramolecular mCB[6]/DAH-HA hydrogels. The BMSCs in the supramolecular HA hydrogels continuously expressed both VEGF-A and HGF, and released the angiogenic factors for a long-term period. The laser Doppler imaging clearly visualized the effective vascular repair and the enhanced blood perfusion in hind-limb ischemia model mice. Our angiogenic factor producing system using BMSCs in the CB[6]/DAH-HA hydrogels might be a promising candidate for various neovascularization therapies.
