The conformal growth of an overlayer of  $\text{Al}_2\text{O}_3$  on a nanocrystalline  $\text{TiO}_2$  film is shown to result in a 4-fold retardation of interfacial charge recombination, and a 30% improvement in photovoltaic device efficiency.

In the last decade, dye-sensitised solar cells (DSSC) have been developed into one of the most interesting alternatives to current solar cell technology for the conversion of sunlight into electrical energy.<sup>1</sup>

A typical DSSC comprises a dye sensitised porous, nanocrystalline titanium dioxide film interpenetrated by a liquid electrolyte containing an  $\text{I}^-/\text{I}_3^-$  red/ox couple. The main charge-transfer events taking place at the  $\text{TiO}_2$ /dye/electrolyte interface are depicted in Scheme 1. Visible light is absorbed (1) by the sensitizer dye (e.g.:  $\text{RuL}_2(\text{SCN})_2$  where L is 4,4'-dicarboxy-2,2'-bipyridyl). Electron injection (2) from the excited state of the dye into the conduction band of the  $\text{TiO}_2$  is followed by the subsequent regeneration of the dye by the  $\text{I}^-/\text{I}_3^-$  red/ox couple (4).

Efficient operation of the DSSC device relies upon the minimisation of the possible recombination pathways occurring at the  $\text{TiO}_2$ /dye/electrolyte interface, allowing efficient charge transport through the  $\text{TiO}_2$  film and electrolyte and subsequent charge collection at the device contacts. There are two possible recombination losses to consider. The injected electrons may recombine either with oxidized dye molecules (3) or with the oxidised redox couple (5); the latter reaction is thought to be particularly critical to device function.

Increasingly research into DSSC is addressing the use of more sophisticated device architectures in order to reduce interfacial recombination losses. Examples include the use of composite metal oxides as the semiconductor e.g.  $\text{SnO}$ ,  $\text{ZnO}$  with different band-gaps,<sup>2</sup> the incorporation of spacer units between the oxidised dye and the  $\text{TiO}_2$  surface,<sup>4</sup> and surface passivation by electrodeposition of insulating polymers.<sup>5</sup> One particularly attractive approach involves the coating of the nanocrystalline metal oxide film with a thin overcoat of another metal oxide with a higher conduction band edge, as illustrated in Scheme 1, with the aim of increasing the physical separation of injected electrons for the oxidised dye redox couple, thereby

retarding the recombination reactions. Previous studies employing this approach have demonstrated significant improvements in DSSC device performance for  $\text{Nb}_2\text{O}_5$  coated  $\text{TiO}_2$  films and  $\text{Al}_2\text{O}_3$  coated  $\text{SnO}_2$  films.<sup>6,7</sup>

In this paper we employ transient laser spectroscopy to probe directly the retardation of interfacial charge recombination caused by coating a nanocrystalline  $\text{TiO}_2$  with an  $\text{Al}_2\text{O}_3$  overlayer. We moreover suggest the simplicity of the coating method presented, may make this approach particularly attractive for the future development of efficient DSSC.

$\text{Al}_2\text{O}_3$  coated nanocrystalline  $\text{TiO}_2$  films were prepared by the following method. An 8  $\mu\text{m}$  thick porous film of nanocrystalline, anatase  $\text{TiO}_2$  was deposited by the doctor blade technique onto fluorine doped conducting tin oxide glass (TEC8) (nanocrystal diameter  $\sim 15$  nm) as previously.<sup>8</sup> An air-stable solution of  $\text{Al}(\text{Bu}^i\text{O})_3$  (Sigma-Aldrich®, 99.9% grade, 0.15 M in isopropanol) under aerobic conditions was used to conformally coat the  $\text{TiO}_2$ . The film was exposed to water vapour for 1 min and dried at 120 °C. After this, the film was dipped in the coating solution for 15 min at 60 °C and, finally, sintered at 450 °C for 15 min in order to remove any remaining organic contaminants. HRTEM data (data to be presented elsewhere) indicate this procedure resulted in a conformal  $\text{Al}_2\text{O}_3$  overlayer with thickness of  $\sim 2$ –2.5 nm. After coating, the samples were sensitised under anhydrous conditions by a standard solution of dye  $\text{RuL}_2(\text{NCS})_2$ † overnight at room temperature, resulting in similar dye loadings for both films (see Table 1).

The influence of this coating procedure upon the kinetics of the recombination reaction (3) was determined using millisecond–microsecond transient absorption spectroscopy, monitoring the decay of photoinduced absorption of the dye cation species in the absence of a red/ox active electrolyte. Data were collected with the sensitised film covered in a 1:1 ethylene carbonate/propylene carbonate solution and glass cover slide following previously published methods.<sup>9</sup> Fig. 1 contrasts the decay kinetics plotted on a logarithmic time scale in the presence and absence of the  $\text{Al}_2\text{O}_3$  overcoat on the  $\text{TiO}_2$  film. The charge recombination kinetics exhibits the previously reported<sup>10</sup> stretched-exponential behaviour ( $\Delta\text{OD} \propto e^{-(t/\tau)^\alpha}$ ). It is apparent that the  $\text{Al}_2\text{O}_3$  overlayer results in a  $\sim 4$  fold retardation of the recombination (half times for dye cation decay of 2.0 and 0.57 ms for the coated and uncoated films, respectively), consistent with the blocking layer function of the  $\text{Al}_2\text{O}_3$  overlayer.

The recombination data shown in Fig. 1 are consistent with a reasonably homogeneous  $\text{Al}_2\text{O}_3$  overlayer thickness. An inhomogeneous overcoat would be expected to result in more

**Scheme 1** Illustration of the interfacial charge-transfer processes occurring at the nanostructured  $\text{TiO}_2$ /dye/electrolyte interface of DSSC. Also shown is the  $\text{Al}_2\text{O}_3$  blocking layer as developed in this paper.

**Table 1** Comparison of the performance parameters of the cells based on  $\text{Al}_2\text{O}_3/\text{TiO}_2$  and  $\text{TiO}_2$  films

|                                        | $V_{\text{OC}}/\text{mV}$ | $J_{\text{SC}}/\text{mA}$ | FF (%) | $\eta$ (%) |
|----------------------------------------|---------------------------|---------------------------|--------|------------|
| $\text{Al}_2\text{O}_3/\text{TiO}_2^a$ | 750                       | 10.9                      | 65     | 5          |
| $\text{TiO}_2^b$                       | 705                       | 8.1                       | 55     | 3.8        |

<sup>a</sup> Absorbance of dye-coated film was 2.28. <sup>b</sup> Absorbance of dye-coated film was 2.30 measured at 550 nm.

**Fig. 1** Transient absorption data probing the decay of photoinduced dye cation absorption (excitation 625 nm, probe 800 nm) at room temperature for (a) an  $\text{Al}_2\text{O}_3/\text{TiO}_2/\text{RuL}_2(\text{NCS})_2$  film and (b) a  $\text{TiO}_2/\text{RuL}_2(\text{NCS})_2$  film. The decay dynamics are assigned to the recombination reaction (3) in Scheme 1.

dispersive (*i.e.* more stretched) recombination kinetics, whereas we observe the coating actually results in less dispersive kinetics (as will be discussed in more detail elsewhere). We furthermore note that coated films exhibited a similar initial signal amplitude to the uncoated films, indicative of similar electron injection yields for both films. This observation is consistent with previous studies<sup>11</sup> of uncoated films which have reported that the rate of the electron injection reaction (2) is  $>10^3$  greater than the excited state decay reaction (6), indicating the injection yield would be insensitive to a four-fold reduction in the rate of electron injection.

The influence of the  $\text{Al}_2\text{O}_3$  overlayer on photovoltaic performance was investigated by the fabrication of a 1  $\text{cm}^2$  'sandwich' DSSC.† Photoelectrochemical measurements were performed according to reported procedures.

Fig. 2 illustrates the photocurrent–voltage curves for cells with and without blocking-layer of  $\text{Al}_2\text{O}_3$ . Open circuit voltage

**Fig. 2** Photocurrent–voltage curves of DSSC with (a) and without (b) the incorporation of an  $\text{Al}_2\text{O}_3$  overlayer under AM 1.5 irradiation. The inset illustrates the dark current in both samples.

( $V_{\text{OC}}$ ), short circuit photocurrent density ( $J_{\text{SC}}$ ), fill factor (FF), and photoenergy conversion efficiency ( $\eta$ ) of the cells are listed in Table 1. We conclude that the  $\text{Al}_2\text{O}_3$  overlay results in a significant improvement in  $V_{\text{OC}}$ ,  $I_{\text{SC}}$  and FF, with an overall 30% improvement in device performance. The improvement in cell voltage is of particular relevance. It should be noted that the control (no overlayer) cells employed in these studies were optimised for compatibility with transient spectroscopy rather than device efficiency. As shown elsewhere, further improvements in device performance should be obtained by the use of scattering metal oxide films, reflective counter electrodes, and reduction in series resistance losses from the electrodes and electrolyte.

The dark current data in Fig. 2 (see insert) indicates that the  $\text{Al}_2\text{O}_3$  overlayer reduces the dark current arising from the recombination reaction (5) in Scheme 1. This is consistent with the observed 45 mV increase in  $V_{\text{OC}}$  of the device under illumination and provides further support for the blocking layer function of the  $\text{Al}_2\text{O}_3$  overlayer. In addition we find this overlayer results in a significant increase in  $I_{\text{SC}}$ , as has been previously reported for  $\text{Nb}_2\text{O}_5$  overlayers.<sup>6</sup> This observation may in part be attributed to an increase in the yield of electron injection, as we discuss above. It may also arise from other factors such as an improvement in electron transport through the metal oxide, as has previously been discussed in relation to  $\text{TiCl}_4$  treatments of such films.<sup>12</sup>

In conclusion we have demonstrated a simple method for the fabrication of conformal  $\text{Al}_2\text{O}_3$  overlayer on nanocrystalline  $\text{TiO}_2$  films, have demonstrated that this overlayer results in a retardation of the kinetics of charge recombination to dye cations (reaction (3)) and a reduction in the dark current (reaction (5)), resulting in 30% overall improvement in device performance under solar illumination.

We gratefully acknowledge the support of the EPSRC and the European Union (Nanomax, NNE5-2001-00192) in funding this research.
