**Abstract:**

A straightforward tandem column separation procedure is presented for separation of Sr, Nd, Pb, and Hf from silicate materials. It allows rapid purification, without any intervening evaporation, of these four elements of great interest in Earth science and cosmochemistry. After sample loading, the upper Sr Spec column adsorbs Sr and Pb, while the lower TODGA Spec column adsorbs Hf and Nd. Strontium-lead and hafnium-neodymium elements are then back-extracted from the Sr Spec and TODGA Spec columns, respectively. The whole separation procedure, including column setup, cleaning, and pre-conditioning, takes approximately eight hours for separating a batch of 25 samples. The proposed procedure offers significant improvement in separation efficiency of these often-used four elements, compared with conventional four columns methods. Fractions of Sr, Nd and Pb are then measured by TIMS and the Hf fraction is determined by MC-ICP-MS. The stability of this procedure was demonstrated by replicate measurements of  $^{87}\text{Sr}/^{86}\text{Sr}$ ,  $^{143}\text{Nd}/^{144}\text{Nd}$ ,  $^{176}\text{Hf}/^{177}\text{Hf}$ ,  $^{206}\text{Pb}/^{204}\text{Pb}$ ,  $^{207}\text{Pb}/^{204}\text{Pb}$  and  $^{208}\text{Pb}/^{204}\text{Pb}$  isotope ratios of eight international silicate rock reference materials, spanning a wide range of bulk compositions. The analytical results obtained in this study agree well with published data. The external reproducibility (2 RSD,  $n = 8$ ) of standard BCR-2 was  $\pm 0.0026\%$  for  $^{87}\text{Sr}/^{86}\text{Sr}$ ,  $\pm 0.0020\%$  for  $^{143}\text{Nd}/^{144}\text{Nd}$ ,  $\pm 0.0049\%$  for  $^{176}\text{Hf}/^{177}\text{Hf}$ , and  $\pm 0.026\% \sim 0.034\%$  for  $^{206}\text{Pb}/^{204}\text{Pb}$ ,  $^{207}\text{Pb}/^{204}\text{Pb}$  and  $^{208}\text{Pb}/^{204}\text{Pb}$  isotope ratios.

**Keywords:** Sr-Nd-Pb-Hf isotope; Tandem column separation; Geological samples; TIMS; MC-ICP-MS

## 1. Introduction

The combination of Sr, Nd, Pb, and Hf isotope systems provide a powerful tool to investigate differentiation and evolution of the silicate Earth and other terrestrial planets.<sup>1-3</sup> This is because the abundances of  $^{87}\text{Sr}$ ,  $^{143}\text{Nd}$ ,  $^{206}\text{Pb}$ ,  $^{207}\text{Pb}$ ,  $^{208}\text{Pb}$  and  $^{177}\text{Hf}$ , vary in natural samples as a consequence of the long-lived radioactive decay of their respective parent isotopes  $^{87}\text{Rb}$ ,  $^{147}\text{Sm}$ ,  $^{238}\text{U}$ ,  $^{235}\text{U}$ ,  $^{232}\text{Th}$  and  $^{176}\text{Lu}$ . As a result,  $^{87}\text{Sr}/^{86}\text{Sr}$ ,  $^{143}\text{Nd}/^{144}\text{Nd}$ ,  $^{206}\text{Pb}/^{204}\text{Pb}$ ,  $^{207}\text{Pb}/^{204}\text{Pb}$ ,  $^{208}\text{Pb}/^{204}\text{Pb}$  and  $^{176}\text{Hf}/^{177}\text{Hf}$  ratios in a geological sample reflect the time-integrated parent-daughter isotope ratios of its source.<sup>4-6</sup> Therefore, it is crucial to extract Sr, Nd, Pb, Hf multi-isotopic messages from the same sample aliquot.

Thermal ionization mass spectrometry (TIMS) and multiple-collector inductively coupled plasma mass spectrometry (MC-ICP-MS) give excellent accuracy and precision regarding Sr, Nd, Pb and Hf isotopic measurements.<sup>4-6</sup> Commonly, using TIMS or MC-ICP-MS, external precision of  $^{87}\text{Sr}/^{86}\text{Sr}$ ,  $^{143}\text{Nd}/^{144}\text{Nd}$ ,  $^{176}\text{Hf}/^{177}\text{Hf}$  isotope ratios are 0.002%~0.004% (2 RSD), and external precision of  $^{206}\text{Pb}/^{204}\text{Pb}$ ,  $^{207}\text{Pb}/^{204}\text{Pb}$  and  $^{208}\text{Pb}/^{204}\text{Pb}$  isotope ratios are 0.02%~0.03% (2 RSD). However, sample preparations for such high precision isotope measurements are time consuming. This is because high precision determination of Sr, Nd, Pb, and Hf isotope ratios in geological samples using TIMS or MC-ICP-MS requires a high degree of sample purification to avoid potential matrix effects as well as poly-atomic and isobaric interferences. Therefore, it is important to develop an integrated separation scheme that enables the analyst to obtain sufficiently pure fractions of Sr, Nd, Pb, and Hf from single sample dissolutions in a straightforward manner. Purification of Sr-Nd-Pb-Hf is

1  
2  
3  
4 traditionally accomplished by using a four-column chromatography after a single  
5  
6 sample digestion. Traditionally, the first column involves the separation of Pb from  
7  
8 other elements using an anion resin such as AG 1 or Dowex 1 resin<sup>24, 26, 28-31</sup>, or a  
9  
10 special resin column, such as Pb Spec<sup>23</sup> or Sr Spec resin<sup>4-6, 25, 27</sup>. The discard  
11  
12 containing most of the Sr-Nd-Hf and matrix element fractions from the first column is  
13  
14 then dried and dissolved using HCl or HNO<sub>3</sub>. Subsequently, Hf is separated from the  
15  
16 matrix solution enriched in Sr, Nd, and Hf using a second resin column, such as anion  
17  
18 resin column<sup>44</sup> or a special resin column, such as LN resin<sup>12, 35, 42</sup>, U-TEVA resin<sup>8, 34, 38,</sup>  
19  
20 <sup>41</sup>, TEVA<sup>33, 36, 37</sup> or TODGA resin<sup>40, 43, 46</sup>. The matrix solution enriched in Sr and Nd  
21  
22 from the second column is also collected. Then, Sr and rare earth elements (REEs)  
23  
24 enriched in Nd are separated from the matrix elements using a third cation exchange  
25  
26 resin (AG50W) column<sup>11-16</sup> or a tandem resin column scheme(Sr Spec + TRU Spec)<sup>19</sup>.  
27  
28 Finally, Nd is separated from other REEs using a fourth resin column, such as  
29  
30 LN(HDEHP) Spec resin<sup>7-12, 16</sup>, HEHEHP resin<sup>21</sup>, or Aminex A27 resin column<sup>15</sup>.  
31  
32 Traditional four-step separation procedures involve tedious pre-cleaning of the  
33  
34 columns and fraction evaporation and take at least four working days to complete  
35  
36 Sr-Nd-Pb-Hf sample preparation for a batch of geological samples (e.g., 20~30  
37  
38 samples). Thus, the separation efficiency of traditional methods is low and sample  
39  
40 throughput is impeded. In addition, traditional methods increase the probability of  
41  
42 contamination from cross-operation in column chemistry associated with the complex  
43  
44 operations.  
45

56 Recently, Yang<sup>17</sup> and Li<sup>18</sup> presented methods to precisely determine <sup>143</sup>Nd/<sup>144</sup>Nd  
57  
58  
59  
60

1  
2  
3  
4 isotopic ratios without separation from other REEs using MC-ICP-MS and TIMS.  
5  
6 Their methods allowed Sr-Nd-Pb-Hf isotopic determination using TIMS and  
7  
8 MC-ICP-MS so well as high-purity Sr, Pb, Hf and REEs-enriched in Nd could be  
9  
10 achieved. Based on this method, rapid chemical procedures in our previous  
11  
12 investigations were developed to separate Sr-Nd-Pb<sup>5</sup> or Sr-Nd-Hf<sup>6</sup> from a single  
13  
14 sample digest. However, analytical protocol to concomitantly separate Sr-Nd-Pb-Hf  
15  
16 fractions from a single sample digest has not been documented. More recent,  
17  
18 Pourmand<sup>46</sup> presents a rapid separation scheme for Sr-Nd-Hf purification using Sr and  
19  
20 TODGA Spec resin. The method<sup>46</sup> gives a clue to afford a possibility of separation  
21  
22 Sr-Nd-Pb-Hf from a single sample digest. In this study, we report a rapid tandem  
23  
24 column separation procedure for all four elements based on optimization of Sr Spec  
25  
26 and TODGA Spec resins.  
27  
28  
29  
30  
31  
32

33 This new method reduces the rather extensive and costly cleaning and separation  
34  
35 procedures of resin and columns without negatively affecting the data quality. This  
36  
37 method of obtaining Sr-Nd-Pb-Hf from a single dissolution thus provides the most  
38  
39 rapid and efficient separation. This method also avoids potentially sample  
40  
41 heterogeneity when the samples are scarce at a given sampling scale. To verify the  
42  
43 robustness of this tandem column separation protocol for Sr-Nd-Pb-Hf, eight certified  
44  
45 reference materials (CRMs) of silicate rocks, encompassing a wide range of matrix  
46  
47 compositions and analyte concentrations, were analyzed.

## 53 2. Experimental

### 54 2.1 Chemicals and chromatographic materials

1  
2  
3  
4 Reagents: All AR grade acids (hydrochloric acid, phosphoric acid, nitric acid,  
5  
6 hydrofluoric acid, boric acid and perchloric acid) were further purified using a  
7  
8 Savillex™ DST-1000 sub-boiling distillation system. Ultrapure water with a  
9  
10 resistivity of  $18.2 \text{ M}\Omega\cdot\text{cm}^{-1}$  was obtained from a Milli-Q Element system (Millipore,  
11  
12 USA) and used throughout this work for diluting concentrated acids. The silica-gel  
13  
14 obtained from Merck company was dispersed in Milli-Q  $\text{H}_2\text{O}$ .  
15  
16

17  
18 Sr-Nd-Pb-Hf standard solutions: A stock solution of 100 ppm Sr, Nd and Pb was  
19  
20 gravimetrically prepared to monitor the stability of the Triton Plus instrument using  
21  
22 NIST NBS-987, JNdi-1 and NIST NBS-981 reference materials. A JMC 475 Hf  
23  
24 international standard solution of 100 ppb was used to monitor the stability of the  
25  
26 Neptune Plus instrument.  
27  
28

29  
30 Re ribbons: 0.035 mm thick, 0.77 mm wide and 99.98% pure, H. Cross Company.  
31  
32

33  
34 Pb double spike: Instrumental fractionation is the major limiting factor precluding  
35  
36 accurate determination of lead isotopic ratios by TIMS. To correct accurately for  
37  
38 effects of the Pb mass fractionation,  $^{204}\text{Pb}$ -enriched and  $^{207}\text{Pb}$ -enriched spikes were  
39  
40 obtained from Oka Ridge National Laboratory, USA. The  $^{207}\text{Pb}$ - $^{204}\text{Pb}$  double spike  
41  
42 composition and the spike/sample mixing ratio were optimally determined by error  
43  
44 simulation using the method reported by Galer<sup>45</sup>. The  $^{207}\text{Pb}$ - $^{204}\text{Pb}$  double spike  
45  
46 solution was diluted with 0.5 M  $\text{HNO}_3$  to 1 ppm and calibrated using NIST NBS-981.  
47  
48

49  
50 Resin: The Sr Spec and TODGA Spec resins produced by Eichrom Technologies  
51  
52 were used for chromatographic extraction. The Sr Spec resin and was based on a  
53  
54 crown ether di-tert-butylcyclohexane-18-crown-6 in octanol,<sup>19, 27</sup> at sorbed onto an  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 inert chromatographic support (particle diameter: 100-150  $\mu\text{m}$ ). The TODGA Spec  
5  
6 resin (particle diameter: 100-150  $\mu\text{m}$ ) was based on a synthesized tridentate ligand  
7  
8 known as N, N, N'N' tetraoctyl-1, 5-diglycolamide.<sup>43</sup>

9  
10  
11 Column: The Sr Spec cation-exchange quartz glass column was 7 cm long with a  
12  
13 5 mm i.d. and 6 mL reservoir, packed with 0.4 mL of Sr Spec resin. The TODGA  
14  
15 Spec cation-exchange polypropylene column was 7 cm long with a 5 mm i.d. and 5  
16  
17 mL reservoir, packed with 0.8 mL of TODGA Spec resin.

18  
19  
20 Rock standard samples: Rock powders of CRMs were obtained from the United States  
21  
22 Geological Survey (USGS) and the Geological Survey of Japan (GSJ). These CRMs  
23  
24 included USGS BCR-2 (basalt), BHVO-2(basalt), BIR-1(basalt) and AGV-2(andesite)  
25  
26 GSJ JG-1a (granite), JA-3 (andesite), JB-2 (basalt) and JB-3 (basalt).

27  
28  
29 Labware: The labware used included 15 and 7 mL PFA Teflon vials with screw top  
30  
31 lids (Savillex Corporation, USA). These vials were used for sample digestion,  
32  
33 solution collection, and evaporation. These vials were cleaned prior to use with a  
34  
35 degreasing agent followed by sequential washing with AR grade  $\text{HNO}_3$ , HCl, and  
36  
37 ultra-pure Milli-Q  $\text{H}_2\text{O}$ .  
38  
39  
40  
41  
42  
43  
44  
45

## 46 **2.2. Sample digestion**

47  
48  
49 To achieve excellent Sr-Nd-Pb-Hf blank levels, all chemistry was performed  
50  
51 inside better than Class 100 chemical workstations located inside a suite of Class  
52  
53 1000 over-pressured clean rooms. Approximately 120~130 mg of rock powder  
54  
55 materials were weighed into a steel-jacketed acid-washed high-pressure PTFE  
56  
57  
58  
59  
60

1  
2  
3  
4 bombs.<sup>6</sup> The samples were dissolved on a hotplate at 190 °C using an acid mixture of  
5  
6 3 mL of 29 M HF, 0.3 mL of 14 M HNO<sub>3</sub> and 0.3 mL of HClO<sub>4</sub> for 4 days. The  
7  
8 dissolved sample solution was then evaporated to dryness and treated overnight with 2  
9  
10 mL of 6 M HCl and 1mL of saturated (~0.46 M) H<sub>3</sub>BO<sub>3</sub> solution at ca. 120 °C on a  
11  
12 hotplate. After the H<sub>3</sub>BO<sub>3</sub> dissolution step, the fluoride gels formed during  
13  
14 decomposition of mafic and ultra-mafic rocks were completely dissolved. 1mL of 6M  
15  
16 HCl was then added to the residues and evaporated to dryness. When cool, the  
17  
18 residues were dissolved in 1.0 mL of 3.5 M HNO<sub>3</sub> + 0.23 M H<sub>3</sub>BO<sub>3</sub> mixture. The  
19  
20 capsule was then sealed and placed on a 120 °C hot plate overnight prior to chemical  
21  
22 separation.  
23  
24  
25  
26  
27  
28  
29  
30

## 31 2.2. Column chemistry

32  
33 Each sample solution was loaded into the Sr Spec resin and TODGA Spec resin  
34  
35 columns arranged in tandem (Fig 1 and Table 1). Before sample loading, the tandem  
36  
37 column was pre-washed in turn with 10 mL of 7 M HNO<sub>3</sub>, 5 mL of H<sub>2</sub>O, and 5 mL of  
38  
39 3.5 M HNO<sub>3</sub>+0.23 M H<sub>3</sub>BO<sub>3</sub> mixture. As shown in Table 1, after complete draining of  
40  
41 the sample solution(1 mL), tandem Sr and TODGA Spec columns were rinsed four  
42  
43 times with 0.5 mL of 3.5 M HNO<sub>3</sub>. At this stage, most Rb, K, Na, Al, Ti, Fe, Mg  
44  
45 (>98%) and Ba (>98%) passed through both the Sr and TODGA Spec columns. Sr  
46  
47 and Pb were strongly retained into the Sr Spec column, and the REEs enriched in Nd  
48  
49 and Hf were strongly retained into the TODGA Spec column. The TODGA Spec  
50  
51 column absorbed significant matrix element (Ca), whereas only minor matrix  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 elements (Ba and Fe) and minor Rb were retained into the Sr Spec column. Then, the  
5  
6 two columns were decoupled and further processed separately (Table 1 and Fig. 1).  
7

8  
9 Firstly, Sr and Pb fraction was stripped from the Sr Spec column. The Sr Spec  
10  
11 column was washed with 3 mL of 3.5 M HNO<sub>3</sub>. Minor matrix elements and all Rb  
12  
13 were removed during this step. Minor Sr (~ 8.1 %) was also washed out in this step.  
14  
15 Then, the Sr fraction, containing ~ 89.8 % of Sr, was stripped with 5.5 mL of 0.05 M  
16  
17 HNO<sub>3</sub>. Finally, most Pb (~93.4 %) fraction was then stripped with 2 mL of 8 M HCl.  
18  
19

20  
21 Secondly, we stripped Hf and Nd fraction from the TODGA Spec column. Minor  
22  
23 residual matrix ( $\leq 2$  %) elements (Mg, Na, Fe, Ti, K, Al) and significant amounts of Ca  
24  
25 (~33 %) were removed with 20 mL of 3.5 M HNO<sub>3</sub>. Then, the remaining Ca (~39 %)  
26  
27 was completely washed with 10 mL of 12 M HCl. The Hf fraction, containing ~ 97.3 %  
28  
29 of Hf, is stripped with 25 mL of 3.5 M HNO<sub>3</sub> + 1 M HF mixture. Finally, the LREEs  
30  
31 containing the Nd fraction (~98.2 %) was stripped with 10 mL of 0.4 M HCl. All Yb,  
32  
33 Lu and other HREEs were washed out with 10 mL of 0.04 M HCl.  
34  
35  
36  
37

38  
39 To eliminate potential interference from minor organic materials in the Sr Spec and  
40  
41 TODGA Spec columns that affect the TIMS measurements,<sup>5, 27</sup> the Sr fraction, the  
42  
43 LREEs fraction-enriched in Nd, the Hf fraction, and the Pb fraction were first  
44  
45 evaporated to dryness, and then digested using 0.3 ml of 14 M HNO<sub>3</sub> on a 180°C  
46  
47 hotplate for 1.5 hours in closed PFA vials. Finally, the digested Sr-Nd-Pb fractions  
48  
49 were dried at approximately 150°C again prior to TIMS measurements. The Hf  
50  
51 fraction was evaporated to dryness on a hotplate at 120°C, taken up in 0.1 mL of 0.5  
52  
53 M HF + 0.8 mL of 3.5 M HNO<sub>3</sub>, and then was ready for MC-ICP-MS analysis. The  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 complete separation procedure, including pre-cleaning of the columns, took  
5  
6 approximately 8 hours for 25 samples or approximately 75 % less time compared with  
7  
8 conventional four-step column chemistry.  
9

### 10 11 12 13 14 **2.3 Thermal ionization mass spectrometry for Sr, Nd and Pb isotopic analysis**

15  
16 Sr, Nd and Pb isotopic compositions were measured using a Triton Plus  
17  
18 (ThermoFisher) at the Institute of Geology and Geophysics, Chinese Academy of  
19  
20 Sciences (IGGCAS) in Beijing. All Sr, Nd and Pb data were acquired by static  
21  
22 multi-collection with the collector array illustrated in Table 2. To eliminate all gain  
23  
24 calibration errors, amplifier gains were calibrated at the start of each day. Before the  
25  
26 commencement of the analysis, a peak-center routine was run, and then, the baseline  
27  
28 was measured. Single Re filament geometry was used to obtain  $\text{Sr}^+$  and  $\text{Pb}^+$  ion beams.  
29  
30 Double Re filament geometry was employed to obtain the  $\text{Nd}^+$  ion beam. Each run  
31  
32 consisted of 140~180 cycles that were divided into 7~9 blocks. Detail sample loading  
33  
34 and TIMS measurement conditions for Sr, Nd and Pb isotope ratios were reported in  
35  
36 our previous investigations.<sup>5,6</sup> The  $^{87}\text{Sr}/^{86}\text{Sr}$  and  $^{143}\text{Nd}/^{144}\text{Nd}$  ratios were normalized  
37  
38 using  $^{88}\text{Sr}/^{86}\text{Sr} = 8.375209$  and  $^{146}\text{Nd}/^{144}\text{Nd} = 0.7219$  for mass bias correction using  
39  
40 the exponential law. Standards NBS-987, NBS-981 and JNdi-1 were analyzed during  
41  
42 the sample measurement period to monitor instrument status. The NBS-987 standard  
43  
44 gave a mean  $^{87}\text{Sr}/^{86}\text{Sr}$  of  $0.710245 \pm 11(2 \text{ SD}, n = 5)$ , and the JNdi-1 standard gave a  
45  
46 mean  $^{143}\text{Nd}/^{144}\text{Nd}$  of  $0.512109 \pm 8(2 \text{ SD}, n = 5)$ . The NBS-981 standard gave a mean  
47  
48  $^{206}\text{Pb}/^{204}\text{Pb}$  of  $16.934 \pm 0.003$ ,  $^{207}\text{Pb}/^{204}\text{Pb}$  of  $15.484 \pm 0.003$ ,  $^{207}\text{Pb}/^{206}\text{Pb}$  of  $0.9144 \pm$

9

#### 10 11 12 13 14 **2.4 MC-ICP-MS for Hf isotopic analysis**

15  
16 Hf isotopic ratios were measured using a Thermo Scientific Neptune Plus  
17  
18 MC-ICP-MS at the IGGCAS. Analyses were performed in the static mode and cup  
19  
20 configurations were shown in Table 2. Typical operating parameters for Hf  
21  
22 measurement using Neptune Plus were reported by Yang et al.<sup>12, 44</sup> Each run consisted  
23  
24 of a baseline measurement and collections of 96~108 cycles that were divided into  
25  
26 8~9 blocks. The integration time was 4 s, and the typical time of one measurement  
27  
28 was ~ 11 min. Isobaric interferences of  $^{176}\text{Yb}$  and  $^{176}\text{Lu}$  on  $^{176}\text{Hf}$  were monitored by  
29  
30  $^{172}\text{Yb}$ ,  $^{173}\text{Yb}$ , and  $^{175}\text{Lu}$ . The effects of these interferences were corrected on-line  
31  
32 using the following values for the stable ratios:  $^{176}\text{Yb}/^{173}\text{Yb} = 0.79323$  and  $^{176}\text{Lu}/^{175}\text{Lu}$   
33  
34  $= 0.026528$ . After column chemistry, Lu/Hf and Yb/Hf ratios were generally  $\leq 1 \times 10^{-5}$   
35  
36 in natural silicate samples, showing no significant difference in ratios before and after  
37  
38 interference correction. After subtraction of the isobaric interferences, the  $^{176}\text{Hf}/^{177}\text{Hf}$   
39  
40 ratio was normalized to  $^{179}\text{Hf}/^{177}\text{Hf} = 0.7325$  for mass bias correction using the  
41  
42 exponential law. To examine the accuracy of Hf measurement by MC-ICP-MS,  
43  
44 samples presented here were interspersed with analyses of the JMC-475 Hf standard.  
45  
46 In this study, 100 ppb of JMC-475 yielded a value of  $0.282149 \pm 14$  (2 SD,  $n = 4$ ),  
47  
48 which was slightly lower than the recommended the well-accepted JMC-475 value of  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

0.282160. Hence, all measured  $^{176}\text{Hf}/^{177}\text{Hf}$  ratios of silicate samples were normalized to the well-accepted JMC-475 value of 0.282160.<sup>9, 12, 36, 41, 44</sup>

### 3. Results and discussion

#### 3.1 Separation protocol using tandem columns

To avoid matrix and isobaric interference effects, efficient chemical separation of Sr, Nd, Pb, and Hf from silicate samples is required. Previous studies<sup>25, 27</sup> have revealed that the Sr Spec resin is an excellent resin for separating Sr and Pb from rock matrix solution. In relatively strong concentrations ( $\geq 3\text{M}$ ) of  $\text{HNO}_3$  acid,<sup>4, 19, 27</sup> Sr and Pb are retained in Sr Spec resin and few matrix elements are retained. Similarly, the selectivity of TODGA spec resin<sup>40, 43</sup> allows the efficient separation of Hf, LREEs, and HREEs from complex rock matrixes using  $\text{HNO}_3$  or  $\text{HCl}$ . In different concentrations of  $\text{HNO}_3$  or  $\text{HCl}$  acid, Ca, Fe, Ti, LREEs, HREEs, and Hf are variably retained in TODGA Spec resin.<sup>43</sup> Hence, it is possible to separate Sr, Nd, Pb, and Hf fractions from silicate matrix solution in sequence using the tandem columns separation procedure, as long as further optimization of both Sr Spec and TODGA Spec resins is undertaken as described below.

To obtain strong absorption of Hf in TODGA Spec resin, TODGA Spec resin is commonly preconditioned<sup>40</sup> using a mixture of  $\text{HNO}_3 + \text{H}_3\text{BO}_3$ . To obtain the best yield of Sr and Pb, previous investigations have documented that the Sr and Pb can be strongly retained in Sr Spec resin in pure  $\text{HNO}_3$  acid media rather than the mixture of  $\text{HNO}_3 + \text{H}_3\text{BO}_3$ . Thus, the question whether or not the Sr and Pb can be also strongly

1  
2  
3 retained in the Sr Spec resin in the mixture of  $\text{HNO}_3 + \text{H}_3\text{BO}_3$  media is unclear. To  
4  
5 directly address this issue, 100 mg of BCR-2 in 1 mL of mixture of 3.5M  $\text{HNO}_3 +$   
6  
7 0.23M  $\text{H}_3\text{BO}_3$  was loaded into the Sr Spec resin column and all fractions from the  
8  
9 loading sample and the washing columns were collected. Before back-extracted Sr  
10  
11 and Pb fractions, only ~10 % of Sr and ~7 % of Pb were lost. Thus, in contrast to pure  
12  
13  $\text{HNO}_3$  acid media, the yield of Sr using a mixture of 3.5M  $\text{HNO}_3 + 0.23\text{M H}_3\text{BO}_3$   
14  
15 loading seems slightly low. Considering conventional silicate sample digestion size ( $\geq$ )  
16  
17 100 mg), it is easy to obtain a sufficient sample size ( $\geq 50$  ng) of Sr and Pb for TIMS  
18  
19 measurements. Hence, a slightly low yield of Sr is acceptable for TIMS  
20  
21 measurements.  
22  
23  
24  
25  
26  
27

28  
29 The order of the resin setup is a crucial consideration. It is similar to the scheme  
30  
31 presented by Pourmand<sup>46</sup> which is devised to purify Sr-Nd-Hf. Pourmand<sup>46</sup> employs a  
32  
33 special vacuum box equipped with a pneumatic pressure regulator to perform  
34  
35 Sr-Nd-Hf chemical separation and give a quick eluting speed. In our case, it is no  
36  
37 need to prepare a special vacuum box because the eluting speed in our column with a  
38  
39 5mm internal diameter is quick and all operations are convenient. As shown in  
40  
41 Figure 1, our columns containing 0.40 mL of Sr Spec and 0.80 mL of TODGA Spec  
42  
43 resins were used as the top and bottom layers, respectively. By reversing the setup  
44  
45 order of the Sr Spec and TODGA Spec resins, Pb passed through the TODGA Spec  
46  
47 resin and was retained into the Sr Spec resin column. However, Sr and Ca are first  
48  
49 absorbed on the TODGA Spec resin. In order to wash out Sr from the TODGA Spec  
50  
51 resin, at least, 10 mL of high concentration ( $\geq 10$  M) of  $\text{HNO}_3$  should be employed.  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 Then, Sr is retained into the Sr Spec resin. However, some matrix elements (Ca, Fe)  
5  
6 are also gradually washed out from TODGA Spec resin and absorbed into the Sr Spec  
7  
8 resin. In order to obtain high purity Sr and Pb, more HNO<sub>3</sub> acid should be used to  
9  
10 eliminate these matrix element effects. Hence, an imperfect column setup will result  
11  
12 in a long chemical procedure for Sr and Pb separation and rising procedure blanks of  
13  
14 Sr and Pb.  
15  
16

17  
18 The concentration of HNO<sub>3</sub> is crucial as the main eluting reagent. Strong HNO<sub>3</sub>  
19  
20 acid is necessary to strongly retain Sr-Pb on the Sr Spec resin, and Hf-Nd on the  
21  
22 TODGA Spec resin. Hence, using strong HNO<sub>3</sub> acid as the loading and rinsing  
23  
24 reagent is crucial to obtain a high yield of Sr, Nd, Pb and Hf. However, strong HNO<sub>3</sub>  
25  
26 acid hamper the rinsing of Ti and Fe from the TODGA Spec resin due to the fact that  
27  
28 the distribution coefficient ( $K_d$ ) value of Ti and Fe is significant elevated with  
29  
30 increasing concentration of HNO<sub>3</sub>.<sup>43</sup> Hence, to quickly wash out Ti and Fe from  
31  
32 TODGA Spec resin, several HNO<sub>3</sub> concentrations (e.g., 3~5 M) were tested to check  
33  
34 which concentration of HNO<sub>3</sub> acid shows the best performance to remove the matrix  
35  
36 elements. After many experimental analyses, we found that moderately strong  
37  
38 concentration (3.5 M) of HNO<sub>3</sub> is most suitable to quickly remove Fe and Ti before  
39  
40 back-extraction of Nd and Hf from TODGA Spec resin.  
41  
42  
43  
44  
45  
46  
47

48  
49 In addition, a mixture of HF +HNO<sub>3</sub> acid was employed as eluting reagent in  
50  
51 previous investigations<sup>40, 43</sup> to get a satisfactory yield of Hf and back-extract Hf  
52  
53 quickly. These studies recommend weak HF (0.2~0.5 M) acid as the eluting reagent  
54  
55 for stripping Hf from TODGA Spec resin. However, our study shows that a large  
56  
57  
58  
59  
60

1  
2  
3  
4 eluting volume is required to achieve a high yield of Hf when using weak HF  
5  
6 (0.2~0.5M) acid. To give a quick eluting Hf, Pourmand<sup>46</sup> employ a hot mixture  
7  
8 solution (1M HNO<sub>3</sub> + 0.2M HF) as eluting reagent. In spite of good yield of Hf is  
9  
10 obtained, the mixture solution must be preheated to 70°C and eluting Hf step should  
11  
12 be performed in ambient temperature of 90°C. Hence, it is inconvenient and  
13  
14 unfriendly for most users who need pre-heat eluting reagent and keep a good  
15  
16 temperature control for eluting solution (70°C) and ambient (90°C) in a special  
17  
18 vacuum box. Hence, it is necessary to search the most suitable eluting reagent for Hf  
19  
20 from TODGA resin. The effect of variation proportion of HNO<sub>3</sub> versus HF in the  
21  
22 mixture, such as 3.5M HNO<sub>3</sub> + 0.3 M HF, 3.5M HNO<sub>3</sub> + 0.5 M HF, 3.5M HNO<sub>3</sub> + 1  
23  
24 M HF, 4.5M HNO<sub>3</sub>+ 0.5 M HF and 4.5M HNO<sub>3</sub>+ 1 M HF, on the yield of Hf and  
25  
26 back-extraction of Hf were further examined. This study showed that the 3.5M  
27  
28 HNO<sub>3</sub>+ 1 M HF mixture is the optimal eluting reagent to obtain a satisfactory yield  
29  
30 and purity of Hf. Thus, the concentration of HF acid in the mixture of HNO<sub>3</sub>+HF  
31  
32 should be higher than 1M otherwise it is difficult to elute Hf quickly.  
33  
34  
35  
36  
37  
38  
39  
40

### 41 **3.2 Purity, recovery, blank and memory effect**

42  
43  
44 To investigate the behavior of matrix and trace elements retained in the tandem  
45  
46 columns, a basalt standard (BCR-2) was employed. A 100 mg aliquot of BCR-2 was  
47  
48 dissolved and loaded onto the tandem columns. Strontium, Pb, Hf and Nd fractions  
49  
50 were collected following the procedure described in Table 1. Semi-quantitative trace  
51  
52 element analyses were performed using a Thermo Fisher Element-XR ICP-MS.  
53  
54  
55  
56 Strontium, Pb and Hf fractions showed very high sample purity. Lanthanum, Ce, Pr,  
57  
58  
59  
60

Sm were also co-existed in Nd fraction. In spite of the  $^{144}\text{Sm}$  isobaric interference exists in TIMS analysis, it is easy to correct using our previously reported method.<sup>18</sup>

In summary, the yield of Sr, Nd, Pb and Hf fractions was good at 89.8 %, 98.2 %, 93.4 %, and 97.3 %, respectively. Procedural blanks are crucial for accurate Sr-Nd-Pb-Hf isotope analysis. In this study, blank values of 30~40, 50~60, 110~130, and 55~65 pg were obtained for Sr, Nd, Pb, and Hf, respectively. Bearing in mind that amounts of analytes processed were 1.3~7.9  $\mu\text{g}$  for Sr, 0.3~3.4  $\mu\text{g}$  for Nd, 0.15~3.1  $\mu\text{g}$  for Pb, 0.08~0.6  $\mu\text{g}$  for Hf, respectively, the contribution of analytical contamination to the separated analytes was negligible. Previous studies show significant memory effect when re-using Sr Spec resin.<sup>5, 25</sup> To eliminate the “memory effect” and obtain the lowest blank, fresh Sr and TODGA Spec resins are recommended to use especially for samples with low concentration of Sr, Nd, Pb, Hf.

### 3.3 Validation of the method and final results

To examine the analytical reproducibility and feasibility of our procedure for silicate samples, eight CRMs were selected to encompass a wide range of matrix compositions, and analyte concentrations were determined. During Sr, Nd and Hf isotope analyses, as shown in Table 3, the  $^{87}\text{Sr}/^{86}\text{Sr}$ ,  $^{143}\text{Nd}/^{144}\text{Nd}$  and  $^{176}\text{Hf}/^{177}\text{Hf}$  ratios of all analyzed USGS and GSJ reference materials were obtained with an internal precision better than 0.005 % (2 RSE), most internal precision was better than 0.003 % (2 RSE) . For Pb isotope analysis, as shown in Table 4,  $^{206}\text{Pb}/^{204}\text{Pb}$ ,  $^{207}\text{Pb}/^{204}\text{Pb}$  and  $^{208}\text{Pb}/^{204}\text{Pb}$  ratios of all analyzed USGS and GSJ reference materials were obtained

1  
2  
3  
4 with an internal precision better than 0.01 % (2 RSE). Average values of  $^{87}\text{Sr}/^{86}\text{Sr}$ ,  
5  
6  $^{143}\text{Nd}/^{144}\text{Nd}$ ,  $^{176}\text{Hf}/^{177}\text{Hf}$ ,  $^{206}\text{Pb}/^{204}\text{Pb}$ ,  $^{207}\text{Pb}/^{204}\text{Pb}$  and  $^{208}\text{Pb}/^{204}\text{Pb}$  in the present study  
7  
8 agreed well with previously published data<sup>4-7, 10-14, 16, 18, 20-22, 24-26, 28-32, 35, 36, 39-41, 44</sup>  
9  
10 obtained using TIMS or MC-ICP-MS. Currently the reference value of the  $^{176}\text{Hf}/^{177}\text{Hf}$   
11  
12 ratio of JG-1a is not available. In this study, we provide the first the high precision  
13  
14  $^{176}\text{Hf}/^{177}\text{Hf}$  value for JG-1a.  
15  
16  
17

18  
19 During  $^{143}\text{Nd}/^{144}\text{Nd}$  ratio determination, the analyte was a LREEs mixture instead  
20  
21 of high-purity Nd. Thus, to further examine whether  $^{144}\text{Sm}$  can be accurately  
22  
23 subtracted from mixed signals of  $^{144}\text{Sm}+^{144}\text{Nd}$ , the  $^{145}\text{Nd}/^{144}\text{Nd}$  ratio of silicate  
24  
25 samples was also measured and corrected following the previously reported method<sup>18</sup>.  
26  
27 As shown in Table 3 and Fig 2, the corrected  $^{145}\text{Nd}/^{144}\text{Nd}$  value is  $0.348406 \pm$   
28  
29  $0.000006$  (2 SD,  $n = 22$ ) in actual silicate samples, which agrees well with reported  
30  
31 values of  $0.348405 \pm 0.000015$ .<sup>4-6, 11, 17, 18, 20, 22</sup> The obtained data imply that the  $^{144}\text{Sm}$   
32  
33 isobaric interference can be accurately subtracted.  
34  
35  
36  
37  
38

39 The BCR-2 CRM has an excellent homogeneity and is widely used to monitor the  
40  
41 quality of chemical procedures and the instrumental status in many geochemical  
42  
43 laboratories. Hence, in this study, we employed BCR-2 to verify the stability of the  
44  
45 procedure. The reproducibility was demonstrated by eight different dissolutions of  
46  
47 BCR-2 powder materials. As shown in Table 3, eight replicate measurements of  
48  
49 BCR-2 yielded a  $^{87}\text{Sr}/^{86}\text{Sr}$  value of  $0.705004 \pm 0.000018$  (2 SD), a  $^{143}\text{Nd}/^{144}\text{Nd}$  value  
50  
51 of  $0.512630 \pm 0.000010$  (2 SD), and a  $^{176}\text{Hf}/^{177}\text{Hf}$  value of  $0.282871 \pm 0.000014$  (2  
52  
53 SD). Strontium, Nd and Hf isotope data of BCR-2 were thus consistent with reported  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4 values.<sup>5, 6, 11, 12, 17, 18, 20-22, 34-36, 40</sup> The external reproducibility of the  $^{87}\text{Sr}/^{86}\text{Sr}$ ,  
5  
6  $^{143}\text{Nd}/^{144}\text{Nd}$ , and  $^{176}\text{Hf}/^{177}\text{Hf}$  ratios of BCR-2 were better than  $\pm 0.0026\%$  (2 RSD),  $\pm$   
7  
8  $0.0020\%$  (2 RSD), and  $\pm 0.0049\%$  (2 RSD), respectively. As shown in Table 4, eight  
9  
10 replicate measurements of BCR-2 yielded  $^{206}\text{Pb}/^{204}\text{Pb}$  value of  $18.758 \pm 0.006$  (2 SD),  
11  
12  $^{207}\text{Pb}/^{204}\text{Pb}$  value of  $15.624 \pm 0.004$  (2 SD) and  $^{208}\text{Pb}/^{204}\text{Pb}$  value of  $38.721 \pm 0.013$  (2  
13  
14 SD). Pb isotope data of BCR-2 were consistent with the reported values.<sup>5, 11, 26, 29, 31</sup>  
15  
16  
17  
18 The external reproducibility of  $^{206}\text{Pb}/^{204}\text{Pb}$ ,  $^{207}\text{Pb}/^{204}\text{Pb}$  and  $^{208}\text{Pb}/^{204}\text{Pb}$  from BCR-2  
19  
20 was  $0.027\sim 0.034\%$  (2 RSD).  
21  
22  
23

24 Overall, the data reproducibility and precision of the proposed method is  
25  
26 satisfactory and completely fills the demands of geochemistry and petrology.  
27  
28  
29

#### 30 31 **4. Conclusions**

32  
33 A rapid and robust tandem chemical separation procedure was developed for  
34  
35 measuring  $^{87}\text{Sr}/^{86}\text{Sr}$ ,  $^{143}\text{Nd}/^{144}\text{Nd}$ ,  $^{176}\text{Hf}/^{177}\text{Hf}$ ,  $^{206}\text{Pb}/^{204}\text{Pb}$ ,  $^{207}\text{Pb}/^{204}\text{Pb}$ , and  $^{208}\text{Pb}/^{204}\text{Pb}$   
36  
37 isotope ratios in the same sample digest. Sr, Pb, and Nd, Hf were sequentially  
38  
39 separated from the same rock matrix solution using tandem columns packed with Sr  
40  
41 Spec resin and TODGA Spec resin without the need for intervening evaporation. The  
42  
43 chemical separation scheme is based on the enhanced elemental selectivity permitted  
44  
45 by the Sr Spec and TODGA Spec resins. The proposed separation procedure achieved  
46  
47 both the satisfactory and rapid separation of Sr, Pb, Nd, and Hf and reduced  
48  
49 cross-contamination, thereby offering significant advantages over existing methods in  
50  
51 terms of simplicity, separation efficiency and waste reduction. High separation  
52  
53 performance was examined by analysing a series of reference silicate rock samples.  
54  
55  
56 The bottleneck associated with sample preparation prior to TIMS and MC-ICP-MS  
57  
58  
59  
60

1  
2  
3 measurements can be significantly reduced using the new protocol.

## Figure captions

**Fig 1.** Tandem column separation scheme in this study compared with the traditional four columns separation procedure

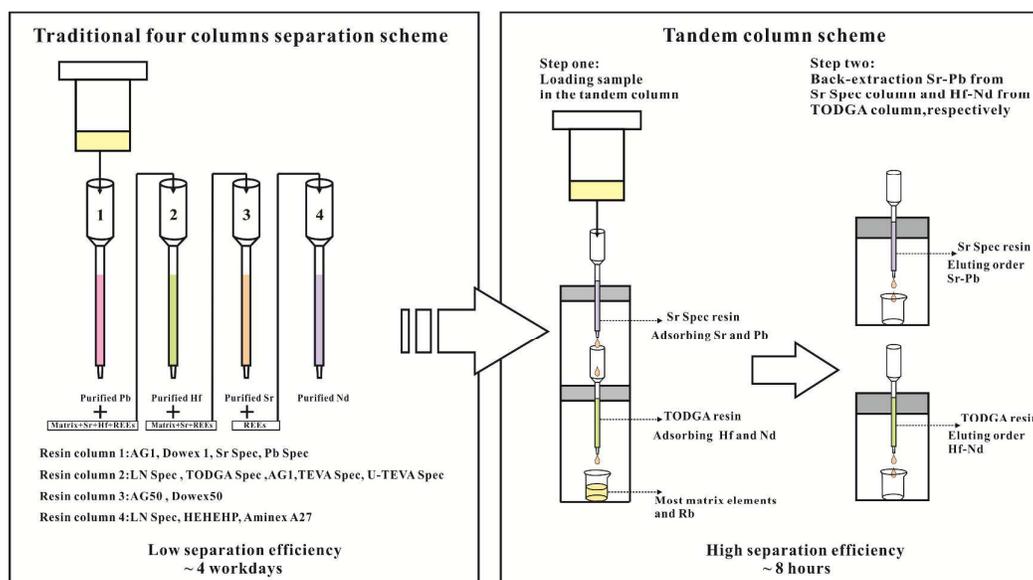

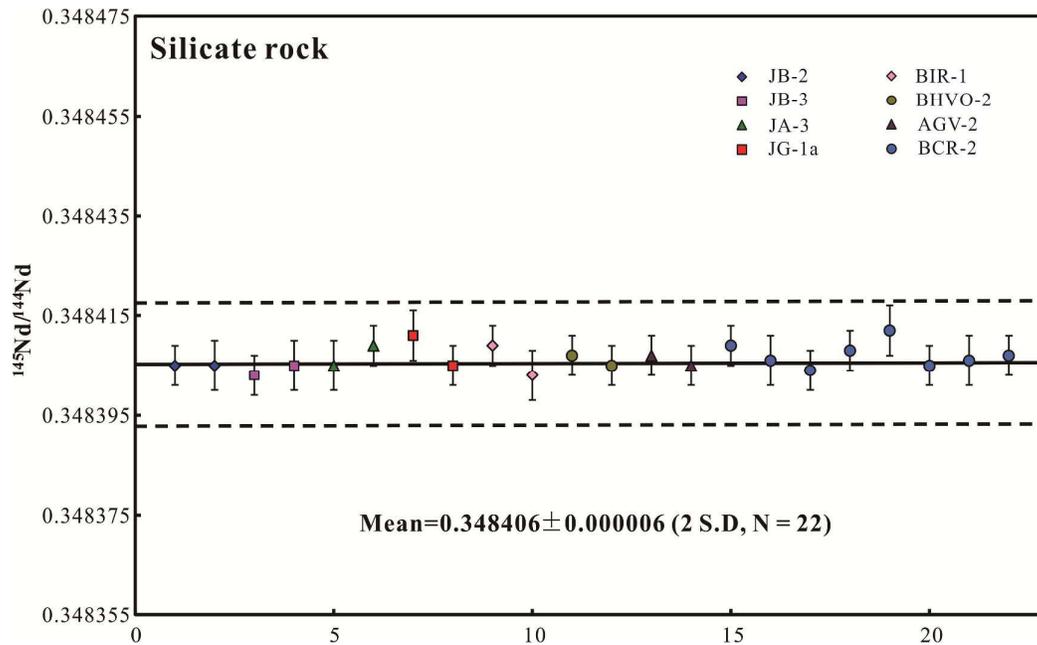

Fig 2. Corrected  $^{145}\text{Nd}/^{144}\text{Nd}$  ratios for silicate rock from USGS and GSJ.

**Table 1. The separation scheme enabling the successive isolation of Sr, Pb, and Nd, Hf by tandem extraction chromatography without intervening evaporations.**

Procedure	Reagents	Eluting Volume(mL)
<b>Tandem column pre-cleaning and sample loading</b>		
Cleaning column	7M HNO <sub>3</sub>	10
Cleaning column	Millipore water	5
Pre-conditioning column	3.5M HNO <sub>3</sub> +0.23M H <sub>3</sub> BO <sub>3</sub>	5
Sample loading	3.5M HNO <sub>3</sub> +0.23M H <sub>3</sub> BO <sub>3</sub>	1
Rinsing matrix	3.5M HNO <sub>3</sub>	2(0.5×4)
<b>Decoupling Sr and Pb from the Sr Spec resin column</b>		
Rinsing matrix	3.5M HNO <sub>3</sub>	3
Eluing Sr	0.05M HNO <sub>3</sub>	5.5
Eluing Pb	8M HCl	2
<b>Decoupling Nd and Hf from the TODGA Spec resin column</b>		
Rinsing matrix	3.5M HNO <sub>3</sub>	20
Rinsing matrix	12M HNO <sub>3</sub>	10
Eluing Hf	3.5M HNO <sub>3</sub> +1M HF	25
Eluing LREEs enriched Nd	0.4M HCl	10
Rinsing Lu,Yb and other HREEs	0.04M HCl	10

Comment: The yield of Sr, Pb, Hf, and Nd is approximately 89.8 %, 93.4 %, 97.3 %, and 98.2 %, respectively.
