Acquisition of absorption and fluorescence spectral data using chatbots†

Masahiko Taniguchi * and Jonathan S. Lindsey 

The field of photochemistry underpins broad scientific endeavors, encompasses diverse molecular substances, and incorporates descriptions of qualitative and quantitative properties, all of which together may be representative of many scientific disciplines. Yet finding absorption and fluorescence spectra along with companion values of the molar absorption coefficient (ϵ) and fluorescence quantum yield (Φ_f) for a given compound is an arduous task even with the most advanced search methods. To gauge whether chatbots could be used to reliably search the literature, the absorption and fluorescence spectra and quantitative parameters (ϵ and Φ_f) for 16 popular dyes and fluorophores were sought using ChatGPT 3.5, ChatGPT 4o, Microsoft Copilot, Google Gemini, Gemini advanced, and Meta AI. In most cases, the values of ϵ and Φ_f returned by the chatbots accurately cohered with known values from established resources, whereas the retrieval of spectra was only marginally successful. The chatbots were further challenged to find data for fictive compounds (e.g., rhodamine 7G). The results from each chatbot were categorized as follows: “fabricated” (provides numbers that do not exist in the context queried), “fooled” (mis-identifies the compound but does not return any data), “feigned” (acts as if the fictive compound is real but does not provide any data), or “faithful” (responds that the compound is not known or is not available). In summary, the present shortcomings should not cloud the view that chatbots – judiciously used – already provide a valuable resource for the challenging scientific task of finding granular data, and to lesser degree, spectral traces for known compounds.

1. Introduction

The first step in photochemistry is the absorption of light, and accordingly, knowledge of the wavelengths and intensity of absorbed light of a given compound is of utmost importance. Many compounds also emit light, which can be desired or undesired; regardless, knowledge of the wavelengths of the emitted light informs about the energy of the excited state, and the intensity of emitted light provides information about competitive excited-state processes. Accordingly, knowledge of the absorption/fluorescence spectra, the molar absorption coefficient (ϵ), and the fluorescence quantum yield (Φ_f) are of fundamental value across the photosciences. Knowledge of these parameters for a given compound impinges on the fields of medical imaging, fluorescence microscopy, photodynamic therapy, photocatalysis, natural and artificial photosynthesis, organic solar cells, and organic light emitting diodes. These

photophysical parameters are also central for identification and quantification of diverse species in biochemistry and medicinal chemistry.

Over the years, we have been working to assemble a curated database of absorption and fluorescence spectra along with computational modules for carrying out quantitative evaluations commonly encountered in the field.^{1–4} The term “curated” refers to the presence of considered spectral traces including values of ϵ and Φ_f (where available), solvent information, and references to the originating literature. Spectra databases have been prepared that include 339 common compounds,^{1,2,4} 12 natural porphyrins,⁵ 150 chlorophylls,⁶ 14 tolyporphyrins,⁷ 324 synthetic chlorins,⁸ 73 phyllobilins,⁹ 177 flavonoids¹⁰ and 220 bilins;¹¹ altogether for the 1309 compounds there are >2000 absorption and fluorescence spectra in the databases.

The accumulation of curated databases has been a tedious task because the existing search methods are woefully inadequate for finding spectral traces and companion values of ϵ and Φ_f .¹² A further challenge is assessing the appropriateness of values reported in the published literature. As one example, the reported values of ϵ and Φ_f for the benchmark compounds zinc(II)tetraphenylporphyrin and free base tetraphenylporphyrin are known to vary widely among hundreds of published papers.¹³ Another area of concern is whether light-scattering

† Electronic supplementary information (ESI) available: Retrieval of the molar absorption coefficient (ϵ) and the fluorescence quantum yield (Φ_f). Questions involving fictive dyes and fluorophores. Retrieval of absorption and fluorescence spectral traces. Comparison of results from ChatGPT 4o and GPT 4.1. See DOI: <https://doi.org/10.1039/d4dd00255e>

corrections have been applied upon acquisition of spectra.¹⁴ After appropriate spectra are identified in the existing literature, digitization is required to generate the requisite XY dataset of intensity *versus* wavelength (or wavenumber) that describes a spectrum.¹⁵ Collections of spectral traces are more valuable than tabulations of wavelength maxima^{12,15–17,19} in enabling important assessments such as molecular brightness¹⁸ and calculation of the spectral overlap term¹⁹ in Förster resonance energy transfer (FRET) processes.²⁰

An alternative to seeking spectral traces is to calculate spectral properties. The *in silico* prediction of properties of organic molecules is not yet fully satisfactory. For example, density functional theory (DFT) with use of appropriate basis sets and parameters (typically divined by testing against a battery of known members in the target family) can now provide deep insight into electronic structure and the origin of molecular transitions as well as reasonably accurate excitation and emission energies, but not the bandwidths, vibronic progressions, and tails that are part and parcel of spectra of organic compounds in the condensed phase. Knowledge of the full spectra – not merely tabulated wavelengths – is essential for the creation and understanding of photoactive materials; the imaginative design of zero-overlap fluorophores by Flood and coworkers²¹ and the identification of fascinating pigments in plants by Bastos and coworkers²² may comprise ideal examples. The *de novo* prediction of a value for the fluorescence quantum yield, which is a consequence of competitive photophysical relaxation processes, is generally beyond the scope of present calculational methods. The question arises, however, concerning the extent to which prediction of spectra of organic molecules can be achieved by artificial intelligence (AI) technologies. For instance, natural language processing (NLP) text mining techniques can be utilized to “scrape” a massive amount of absorption and fluorescence spectral data from the literature.^{23,24} On the basis of acquired experimental data,^{25–31} in conjunction with experimental and DFT calculated data^{32–34} or solely DFT calculated data,^{35–41} machine learning (deep learning) has been used to predict spectra for organic molecules. The significant challenges to mining the extraordinary wealth of information in the chemistry literature, and possible resolutions to present limitations, have been

articulated by Risko and coworkers, taking the venerable task of laboratory recrystallization as a case study.⁴²

Chatbots, of which ChatGPT is perhaps the most popular and representative, are human-like conversational-styled AI software packages that rely on large language models and are integrated into web-based graphical user interfaces. Here, we report the capability of six chatbots for (i) data retrieval of absorption and fluorescence spectral parameters, and (ii) finding absorption and fluorescence spectral traces. The chatbots are ChatGPT (version 3.5 and 4o, OpenAI), Copilot (Microsoft), Gemini and Gemini advanced (Google), and Meta AI (Meta). The spectral traces and data are sought for compounds that are well-known in the fields of photochemistry and photobiology. The core issue is whether chatbots can ameliorate the tedious tasks of finding the spectral traces and critical companion granular information of ϵ and Φ_f for specific well-known compounds and thereby accelerate the assembly of curated spectral databases (Fig. 1). A surprising outcome is that regardless of the present shortcomings, we likely are standing at the dawn of chatbots, which already comprise innovative tools for appropriately chosen applications. The integration of AI technologies into photochemistry research should accelerate development of organic molecule-based dyes and fluorophores.

2. Materials and methods

2.1 General

The questions were addressed to four major chatbots and their variants (ChatGPT 3.5, and 4o; Copilot; Gemini and Gemini advanced; Meta AI) and the resulting responses were analyzed manually. ChatGPT 3.5, Copilot, Gemini, and Meta AI are freely accessible through web interfaces, while ChatGPT 4o and Gemini advanced are subscription-based paid platforms (~\$20 per month). Copilot provides control over conversation styles with three different levels depending on the nature of the answer (creative, balanced, precise); the precise style was chosen for this study. All the questions were made from a single user account in each platform in the period May 24–26, 2024. Each question was fed to chatbots only once, which is referred to as a zero-shot prompt.^{43,44}

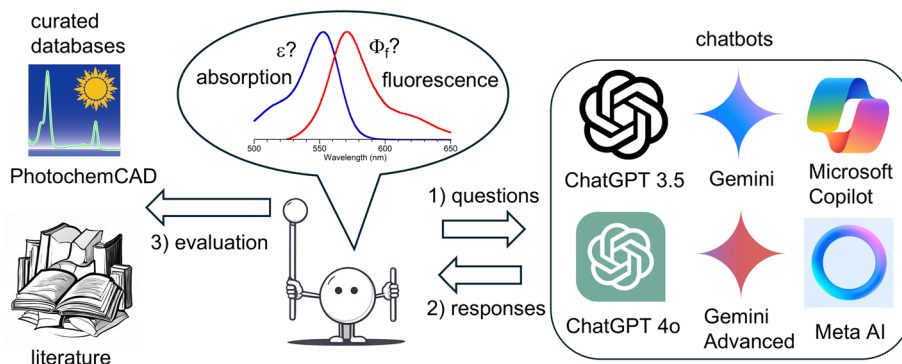

Fig. 1 The development of curated databases of spectra (e.g., PhotochemCAD) has required meticulous searching in the literature, which may be ameliorated through the use of chatbots.

2.2 Retrieval of the molar absorption coefficient (ϵ) and the fluorescence quantum yield (Φ_f)

The values of ϵ and Φ_f were sought for the 16 organic dyes and fluorophores shown in Chart 1 [naphthalene, anthracene, 8-anilinoanthracene-1-sulfonic acid (ANS), 9,10-diphenylanthracene, quinine, acridine orange, coumarin 1, fluorescein, rhodamine 6G, tetraphenylporphyrin (TPP), chlorophyll *a*, chlorophyll *b*, chlorophyll *d*, chlorophyll *f*, indocyanine green (ICG), Alexa Fluor 488]. The questions to the chatbots were made as simple as

possible without providing details concerning solvents, experimental conditions, and instrumental settings. The following questions were given to the chatbots: (i) What is the molar absorption coefficient of “compound name”? (ii) What is the fluorescence quantum yield of “compound name”? No limitation to the number of words was set so as to gain broader responses from the chatbots. All the chatbot responses are displayed in the ESI.† All values of ϵ are listed herein with implicit units of $\text{cm}^{-1} \text{M}^{-1}$ unless noted otherwise; the units have been omitted for clarity.

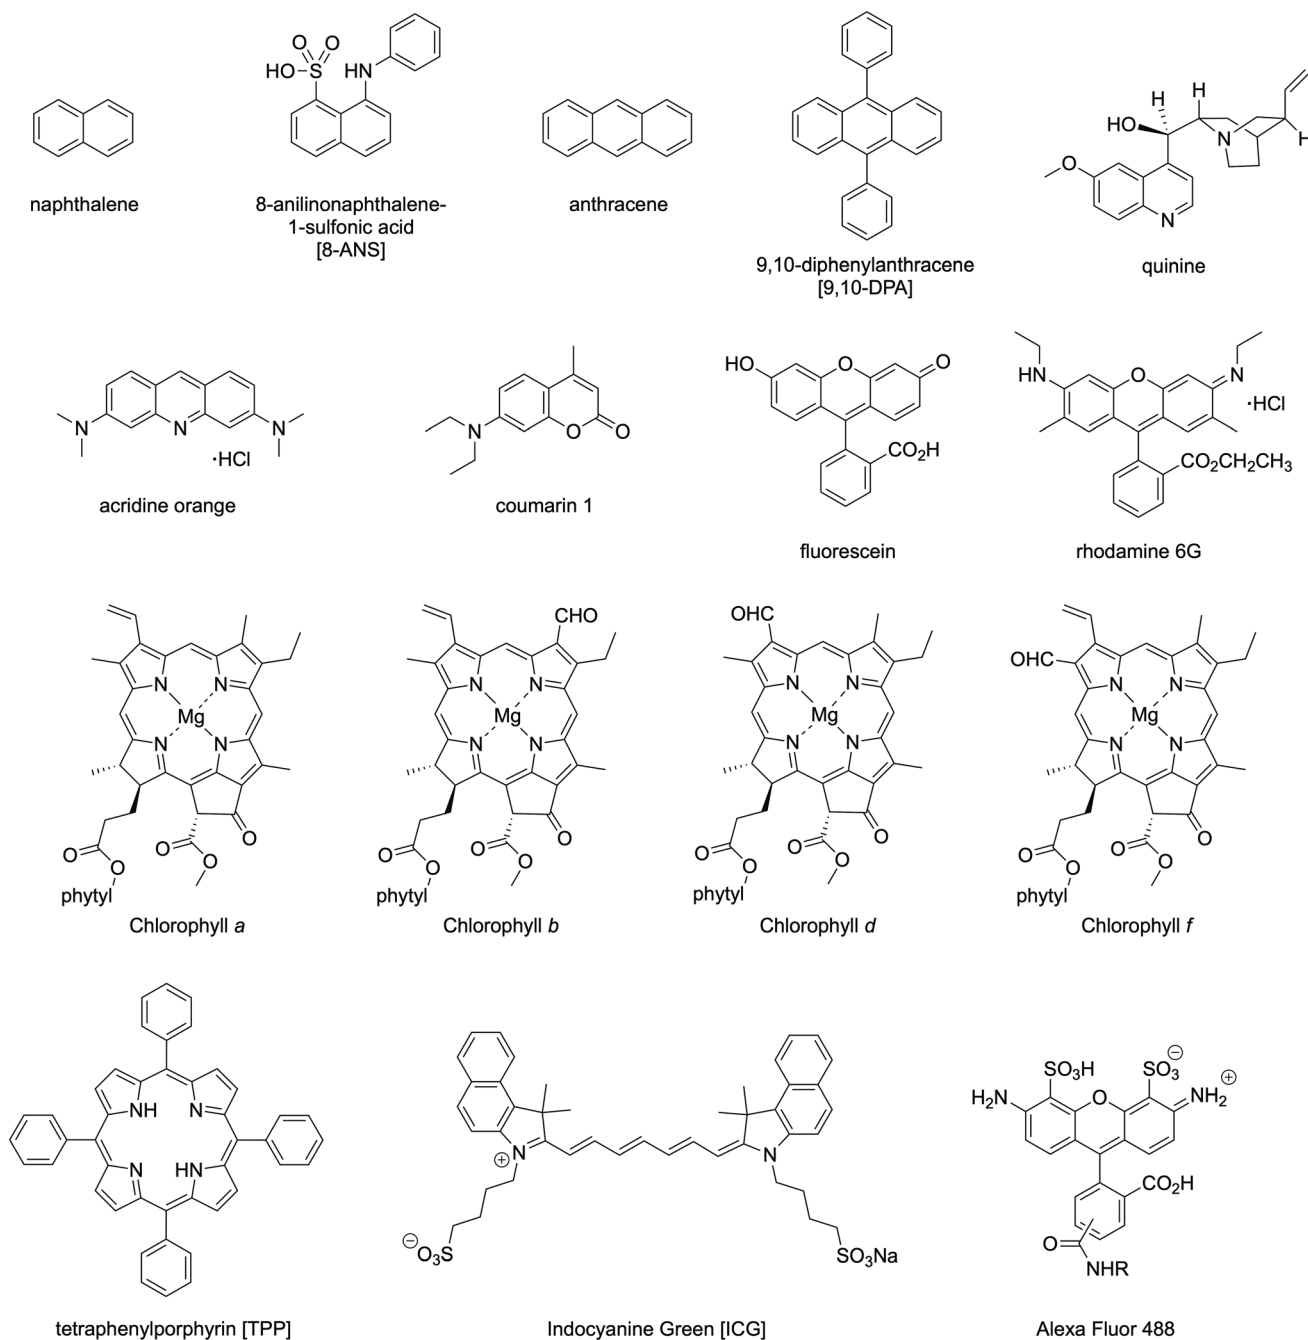

Chart 1 Chemical structures of dyes/fluorophores examined.

2.3 Questions pertaining to fictive dyes and fluorophores

ChatGPT has a somewhat notorious reputation for making up facts and data from relevant information on some occasions due to a lack of deep understanding of the subject.⁴⁵ To challenge whether chatbots can distinguish fake compounds that at first glance have a veneer of correctness but are not real, the ϵ or Φ_f of each of the following six fictive compounds was queried: 10,10-diphenylanthracene (wrong chemical bond structure), coumarin 808, chlorophyll *k*, Lucifer Red, rhodamine 7G, and Alexa Fluor 850 (Table 1).

2.4 Retrieval of absorption and fluorescence spectral traces

To gauge the current chatbot capability of handling graphical images, questions 7–10 were fed to chatbots (Table 2). Questions 7–9 are relatively simple tasks to identify the spectrum of a popular compound (*i.e.*, published in many articles), while question 10 requires domain specific knowledge.

Data from reliable sources are used for comparison with the responses from the chatbots. The data sources listed in the chatbots upon the question are categorized into four groups: (i) database freely accessible on the internet,^{46,47} (ii) data from chemical vendors,^{48–57} (iii) miscellaneous web site^{58–60} and (iv) published journal articles.^{61–88} Many chatbots refer to PhotochemCAD databases hosted in the Oregon Medical Laser Center (OMLC)⁴⁶ as the sources. The program PhotochemCAD and accompanying spectral database of 125 compounds were conceived around 1980 at The Rockefeller University by one of us (J. S. L.),^{12,15} originated and developed by our group in the mid-late 1980s at Carnegie Mellon University, and first published in 1998¹ following a move to NC State University in the mid-1990s.³ The goal has always been that the spectral data can be freely downloaded for use by others. Sometime thereafter, the near-entirety of the PhotochemCAD spectral data and companion references were republished on a website at Oregon Medical Laser Center (OMLC). The chatbots may access the latter but not download the spectral data from the original

PhotochemCAD site, hence the often-incomplete referencing by the chatbots concerning the true origin of the data (the PhotochemCAD spectral databases were expanded to 150 compounds and published in 2005 as PhotochemCAD 2.² PhotochemCAD 3 database was expanded to 336 compounds in 2018 (ref. 4) and expanded further to >2000 absorption and fluorescence spectra in the databases as stated in the Introduction.)

3. Results and discussion

3.1 General responses from chatbots

The responses from ChatGPT (3.5 and 4o) are relatively short and are provided without any source or web link. The responses from Copilot provide the source and multiple web links, and the responses can be exported as word, pdf, or txt files. The web links of Copilot were not very well organized at the time of this research. The responses of Gemini (and Gemini advanced) are precise and somewhat wordy, which come with web links whenever sources are available. Gemini (and Gemini advanced) are also equipped with a “double-check response” button, which initiates a Google search to find relevant content from web resources; however, information germane to the response depends on the contents of the responses and is often not found. The responses from Meta AI are well organized with web links as sources of the information in a 1 : 1 relationship.

3.2 Retrieval of the molar absorption coefficient (ϵ)

The results for chatbot retrieval of ϵ values are summarized in Table 3. How to evaluate the accuracy of an ϵ value found by chatbots? Here, as long as the information provided by chatbots can be matched with a value from the sources, the data are judged as accurate regardless of any disparity from the true values (*i.e.*, authentic, generally accepted values) found in reliable sources. The rationale for this approach is that chatbots are not culpable for errors (real or typographical) that contaminate the sources used for training. If discrepancies are found from the value provided by chatbots and that found in the sources provide by chatbots, the data are judged as inaccurate. For ChatGPT 3.5 and 4o, which do not provide data sources, the accuracy allowance of the data was set at 0.5–2.0 times the values from the reliable sources, a variance chosen given the typical variations of measurement conditions. The ϵ and absorption maxima (λ_{\max}) may vary depending on the solvents, but the choice of solvent was not included in the question. Chatbots may provide more accurate responses if the solvent is specified in the questions; however, doing so crimps the availability of the data. Hence, the questions here were intentionally made as simple as possible.

Each chatbot generally retrieved a value for ϵ , but with accuracy dependent on the given chatbot and particular compound. The values in question have been flagged in Table 3. Chatbots recognize two chief elements of absorption spectra: (i) the ϵ value depends on the wavelength, and (ii) the absorption spectrum may consist of multiple peaks. Most of the responses from chatbots include information on the wavelength (at λ_{\max}) as well as values at other wavelengths (*e.g.*, for multi-banded

^a Reported values are significantly different from the authentic, generally accepted data. ^b Data from PhotochemCAD are curated, and original literature sources are provided therein.

spectra), whenever applicable, without a specific request in the questions. In general, the data accuracies of ChatGPT 3.5 and 4o (9 out of 16 for both) were inconsistent and hence the two chatbots were unreliable as a sole source of a value of ϵ . On the other hand, Copilot, Gemini, Gemini advanced and Meta AI were surprisingly reliable. In particular, Copilot and Meta AI did not afford apparently fabricated data; indeed, those cases with wildly disparate data were reported faithfully from the cited source, but the data in the source itself were incorrect. The retrieval results are reported in detail along with our analyses as described below:

(i) The absorption spectra of (polycyclic) aromatic hydrocarbons typically exhibit strong ethylenic bands (E_1 and E_2 bands) and weak benzenoid bands (B bands).^{61,63} For example, the absorption spectrum of benzene consists of an E_1 band (~ 180 nm, $\epsilon = 60\,000$), E_2 band (~ 200 nm, $\epsilon = 8000$), and tiny B band (255 nm, $\epsilon = 215$).⁶¹ Although the E bands are documented in classical articles,^{61,63–65} such absorption features are often omitted in modern articles and authoritative treatises.⁶² The apparent rationale for the omission is perhaps not because the absorption is <250 nm, but because the E bands arise from an $S_0 \rightarrow S_2$ transition. Immediate relaxation occurs therefrom to the S_1 excited state; hence, E bands do not contribute directly to fluorescence. Some chatbots chose the E_1 band for the wavelength for the ϵ value. Therefore, spectral traces of polycyclic aromatic hydrocarbons (naphthalene, anthracene, 1,8-ANS, and 9,10-DPA) were freshly measured here and are displayed from

200 nm to capture the E bands (Fig. 2). For the spectra in Fig. 2, the ϵ values of naphthalene and anthracene were applied from representative literature values,⁶⁴ while those of 1,8-ANS and 9,10-DPA were redetermined herein.

The absorption spectrum of naphthalene comprises a strong E_1 band (221 nm, $\epsilon = 133\,000$), multiple E_2 bands (~ 275 nm, $\epsilon = \sim 6000$), and a weak B band (311 nm, $\epsilon = \sim 300$) (Fig. 2, panel a). ChatGPT 3.5 and 4o chose the E_1 band (216 and 220 nm, respectively) for the wavelength; however, the corresponding ϵ values were ~ 5 to ~ 9 times less than the actual values. All other chatbots culled the E_2 band maxima and quote 6000 as the ϵ value of naphthalene.

The absorption spectrum of 1,8-ANS exhibits solvent effects; for example, the ϵ value in water and ethanol vary depending on the sources from 4000 to 8000.^{47–49,66} The new measurement of the ϵ value here is 3780 at 354 nm in water and 5810 at 375 nm in ethanol (Fig. 2, panel b). ChatGPT 3.5 applied the data in ethanol (375 nm),⁶⁶ while ChatGPT 4o adopted the data in water 4950 at 350 nm.^{48,64} The molar absorption coefficient is listed as E^{mM} unit (equal to $\text{cm}^{-1} \text{mM}^{-1}$) in a catalogue from the dye vendor,^{48,49} which requires conversion to $\text{cm}^{-1} \text{M}^{-1}$. Gemini advanced successfully converted and responded in proper units, while Copilot was incapable of the unit conversion, in which case the value is listed as is.

The absorption spectrum of anthracene also comprises a strong E_1 band (252 nm, $\epsilon = 180\,000$), multiple E_2 bands (maxima at 356 nm, $\epsilon = 7400$ measured here; 9700 in the

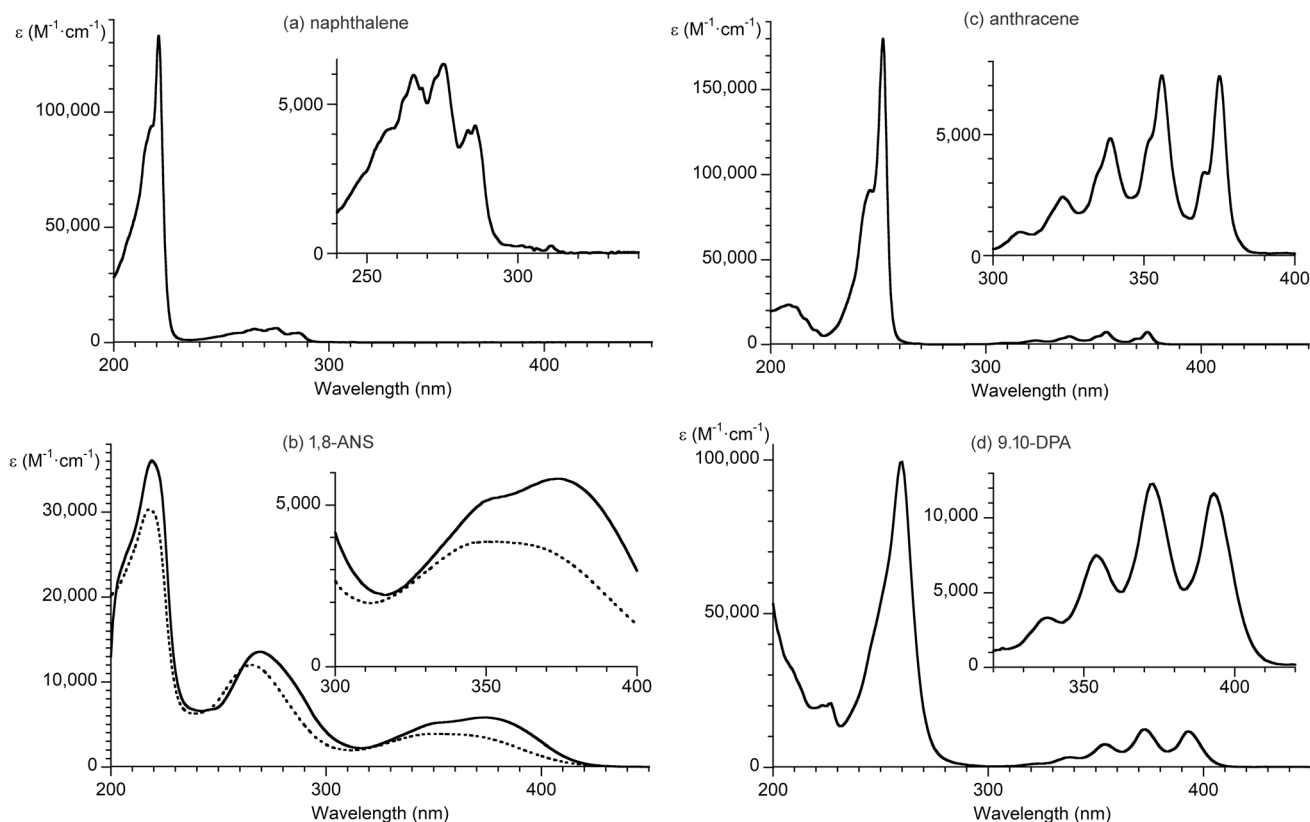

Fig. 2 Absorption spectra at room temperature of (a) naphthalene in *n*-heptane, (b) 1,8-ANS in ethanol (solid line) and in water (dotted line), (c) anthracene in *n*-heptane, and (d) 9,10-DPA in cyclohexane.

literature⁴⁷), and the B band is submerged into the region of the E₂ bands (Fig. 2, panel c). ChatGPT 3.5 picked the longest wavelength E₂ band (374 nm, $\epsilon = 10\,300$), and the value is in an acceptable range. ChatGPT 4o denoted the positions of the E₁ (252 nm) and E₂ (350 nm) bands correctly; however, the ϵ values were completely unreasonable. All other chatbots properly employed the data from literature values.⁴⁷

9,10-DPA exhibits four absorption peaks at wavelengths greater than 300 nm: 338 nm ($\epsilon = 4000$), 354 nm ($\epsilon = 8740$), 373 nm ($\epsilon = 14\,000$), and 392 nm ($\epsilon = 9200$) (Fig. 2, panel d). These values are based on literature data,⁴⁷ whereas the data shown in the figure are different by as much as 20%. ChatGPT 3.5 denoted the first peak (333 nm) whereas ChatGPT 4o picked the second peak (354 nm); however, the ϵ values were over-estimated. All other chatbots properly employed data from literature values.⁴⁷

(ii) All chatbots responded quite well to the questions for the long-established fluorophores quinine, fluorescein, and rhodamine 6G.

(iii) The absorption spectrum of acridine orange is drastically altered by protonation/deprotonation⁷⁰ and is concentration-dependent due to monomeric and dimeric forms.^{68,70,75} As determined here, the absorption maximum of acridine orange in ethanol (490 nm, $\epsilon = 48\,600$) is shifted hypsochromically and hypochromically in basic ethanol (431 nm, $\epsilon = 21\,900$) (Fig. 3).

The ϵ values reported in the literature^{67–76} for acridine orange are summarized together with the data measured herein, as shown in Table 4.

The responses from ChatGPT 3.5 and 4o were based on data in ethanol solution and are in a reasonable range (~ 495 nm, $\epsilon = 40\,000$ or $70\,000$). The responses from Copilot and Meta AI were values in basic ethanol that originate from literature data (431 nm, $\epsilon = 27\,000$).⁴⁷ The response from Gemini advanced was affected by the propagation of misplaced values from the commercial vendor's data,⁵⁰ which are composed of the molar absorption coefficient in basic ethanol ($\epsilon = 27\,000$) and the wavelength maxima (492 nm) in ethanol.

(iv) The ϵ value of coumarin 1 from ChatGPT 3.5 ($\epsilon = 26\,000$) and 4o ($\epsilon = 29\,000$) was close to the value from PhotochemCAD ($\epsilon = 23\,500$); however, the corresponding absorption wavelength

431	21 900	Basic ethanol	This work

($\lambda_{\max} = 350$ nm) is different from the value from PhotochemCAD ($\lambda_{\max} = 375$ nm). On the other hand, all other chatbots provided the values from PhotochemCAD. The ChatGPTs were found to tend to estimate and give approximate values in the current study, which may stem from the characteristic features of ChatGPTs.

(v) The absorption spectra of chlorophylls *a*, *b*, *d*, and *f* are displayed in Fig. 4 to visually guide the comparison described below. The spectra are drawn from a comprehensive database of chlorophyll spectra⁶ that have been included in PhotochemCAD.

The ϵ value of chlorophyll *a* from ChatGPT 3.5 was 0.25–0.5 times that of the values from PhotochemCAD, whereas the values from ChatGPT 4o were highly likely taken directly from PhotochemCAD data. The ϵ values of chlorophyll *b* from ChatGPT 3.5, ChatGPT 4o and Gemini advanced were also far less than the widely accepted value.

(vi) The ϵ value of chlorophyll *d* from ChatGPT 4o is given for the peak position for the Q band (662 nm); however, 662 nm is not a peak maximum. The correct value is 697 nm, and the given molar absorption coefficient (21 000) is 0.3 times that of the accepted value (63 680). Discrepancies of 35 nm in peak position and 3-fold in peak intensity are profound errors in the

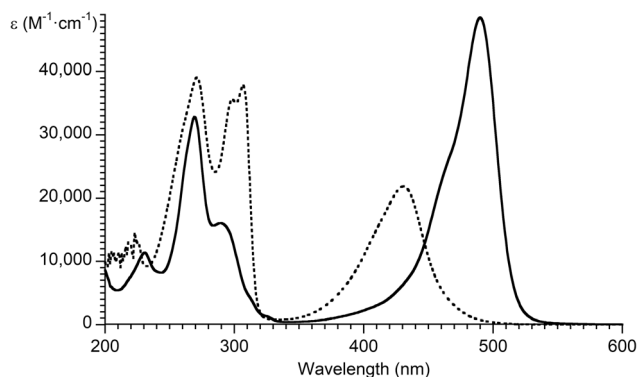

Fig. 3 Absorption spectrum of acridine orange in ethanol (solid line) and basic ethanol (dotted line).

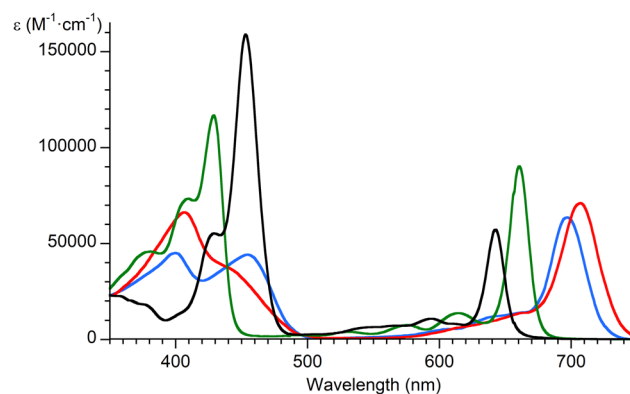

Fig. 4 Absorption spectra of chlorophylls *a* (green, in diethyl ether), *b* (black, in diethyl ether), *d* (blue, in methanol), and *f* (red, in methanol).⁶

context of function in a photosynthetic apparatus as well as in many other systems. Gemini advanced returned a source journal reference for chlorophyll *d* and *f* wherein the title, journal name, year, and volume were correct; the list of authors was only partially correct (key author Blankenship was excluded whereas the estimable chlorophyll scientist Scheer was erroneously included); and the journal page number was wrong. Such errors were easy to spot. Such errors in this field are referred to as fabrication.

(vii) The ϵ value of chlorophyll *f* from ChatGPT 4o fabricated an additional peak (740 nm) that is non-existent. The values for chlorophyll *f* from Gemini ($\epsilon = 57\,500$ at 705 nm) and Gemini advanced ($\epsilon = 71\,000$ at 437 nm and $\epsilon = 56\,800$ at 706 nm) also were fabricated, even though the values were close to those reported in the specified reference by Gemini and Gemini advanced.⁷⁹ On top of that, the absorption maximum for the near-ultraviolet absorption band (termed the B band) from Gemini advanced (437 nm) was completely incorrect; the correct value is 406.5 nm.

(viii) The ϵ value of TPP from both Copilot and Meta AI was incorrect ($\epsilon = 4450$ at 532 nm). The sources were from different web-based homework helpers for students: Bartleby for Copilot and Chegg for Meta AI. The original text material displayed in Bartleby⁵⁹ was identical with that in Chegg⁶⁰ as shown in Fig. 5 (also see the ESI† for screenshots of the web site).

The absorption spectrum of TPP is comprised of a strong band in the blue region (denoted as B) and a set of comparatively weaker bands in the green-red region (denoted as Q); however, no peak exists at 532 nm. The absorption spectrum of TPP is shown in Fig. 6.⁸ The source of the material shown in Fig. 5, presumably drawn from a textbook, could not be located regardless of further internet searches or examination of diverse printed materials. The origin of the inaccurate data (peak at 532 nm) is unknown. This subtle but non-negligible incident exemplifies how the propagation on the internet of pernicious errors concerning properties of even the most common benchmark materials can damage scientific research and corrode understanding.

(ix) The ϵ value of ICG from Gemini advanced ($\epsilon = 78\,000$) was provided without any sources and was dissimilar to the values from other retrieved data or known from other sources.

(x) The ϵ value of Alexa 488 from Gemini advanced ($\epsilon = 91\,400$) was slightly different from other retrieved data or known from other sources. The disparity appears to be due to the different environment (the value was for Alexa 488 conjugated to secondary antibodies, but no sources were provided).

It is noteworthy that all chatbots provided the wavelength (nm) together with the ϵ value even though in most cases the

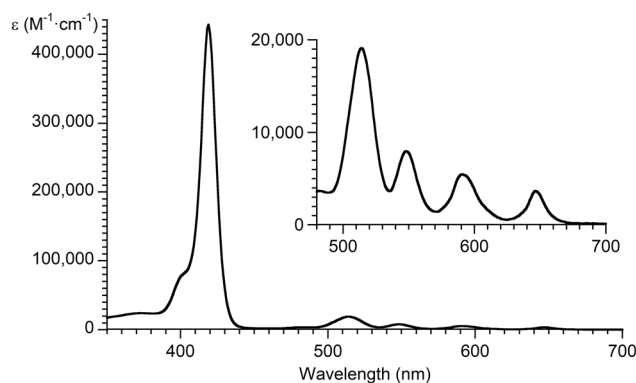

Fig. 6 Absorption spectrum of TPP in toluene at room temperature.⁸

question requested only the latter parameter. The ϵ value varies depending on the wavelength and is senseless without a specified wavelength. An absorption spectrum typically consists of multiple peaks due to the presence of distinct electronic levels often each accompanied by a manifold of vibrational energy levels; therefore, it is not easy to describe a spectrum solely by tabulated numbers without the spectral trace, as shown by the material in this section. The availability of spectra is an essential matter in the photosciences.^{12,15–17,19}

3.3 Retrieval of the fluorescence quantum yield (Φ_f)

The results of data retrieval for Φ_f values by chatbots are summarized in Table 5 together with data from reliable sources. The data retrieval for the Φ_f from chatbots was straightforward and successful for the most part. The Φ_f values for naphthalene, anthracene, 9,10-DPA, quinine, fluorescein, rhodamine 6G and Alexa Fluor 488 were retrieved accurately by all chatbots.

The responses from ChatGPT 3.5 and 4o are distinctive: dramatic improvements in the accuracy of data retrieval were observed for ChatGPT 4o compared to ChatGPT 3.5. The responses from ChatGPT 3.5 were unreliable; indeed, the responses for the Φ_f values of chlorophylls indicated each was a weakly fluorescent compound. A major drawback of the ChatGPT family is the absence of reported data sources (*e.g.*, web links or research articles). ChatGPT 4o performed considerably well for the 16 compounds listed here, but of course that does not imply that ChatGPT 4 will afford reliable results for the Φ_f value of other compounds. Indeed, for a non-expert, the absence of annotation of sources presents a situation where the retrieved values must be taken on faith.

The following are notable points.

iv. Tetraphenylporphyrin (TPP) has a molar absorption coefficient of $4450\text{ M}^{-1}\text{cm}^{-1}$ at 532 nm. TPP has a fluorescence quantum yield of 0.11. A $27\ \mu\text{M}$ solution of TPP is irradiated with a $2\ \mu\text{J}$ pulse of 532 nm laser light in a 1 cm cuvette, how many photons are emitted as fluorescence from the sample.

Fig. 5 Image of (erroneous) parameter values in a source material^{59,60} cited by a chatbot.

^a Reported values are significantly different from the authentic, generally accepted data. ^b Data from PhotochemCAD are curated, and original literature sources are provided therein.

(i) The Φ_f value of 1,8-ANS exhibits a strong solvent dependence and ranges from 0.004 in water to 0.63 in *n*-octanol.⁸² The Φ_f value of 1,8-ANS retrieved from Gemini advanced and Meta AI was actually for 1,8-ANS derivatives – not 1,8-ANS itself – and although those values were very close by coincidence,⁸¹ the data retrieval by Gemini advanced and Meta AI are judged as unsuccessful.

(ii) The web links of PubMed are often embedded as sources (especially by Gemini), and in most of the cases, the links are valid; however, an invalid (fabricated) PubMed ID was provided for the Φ_f value of acridine orange.

(iii) The initial response for chlorophyll *a* from Meta AI was the Φ_f value of oceanic phytoplankton, not that of the molecule chlorophyll *a*. While phytoplankton likely contain chlorophyll *a*, the former is a living organism whereas the latter is a molecule; the chatbot mixup is non-trivial. A more specific question “What is the fluorescence quantum yield of the chlorophyll *a* molecule?” to Meta AI generated reasonable answers (0.32 and 0.25).

(iv) The response for TPP from Gemini reflects the lethal problem of the incapability of distinguishing chemical derivatives by generative AI. The response included not only the Φ_f value of TPP (0.11) but also that of the zinc chelate of TPP, namely Zn-TPP (0.03). This is a common problem for not only all chatbots but also the results from search engines. The responses for TPP also reflect a longstanding problem perhaps appreciated only by the photosciences aficionado – that values of Φ_f depend on a number of experimental conditions, including whether the solution is aerated or deaerated, and even if aeration is controlled and specified, the reported values can span a distressingly large range.¹³ The recent consensus values for Φ_f of TPP are 0.090 in deaerated toluene *versus* 0.070

in toluene in air,¹³ replacing a longstanding reliance on the generic value of 0.11 for the Φ_f of TPP in toluene. The passage of time – and perhaps the advent of more powerful chatbots – may be required for the new values to supplant the old.

(v) To our knowledge, there is only one reported value for the Φ_f of chlorophyll *d* [0.36 in benzene],⁸⁶ and only two values for chlorophyll *f* [0.39 in benzene⁸⁶ and 0.16 in pyridine⁸⁵]. The latter two values were recorded by different research groups and could reflect different experimental methods or true solvent effects. Thus, it is quite understandable that most chatbots have trouble retrieving the data. Note that ChatGPT 4o quoted the Φ_f value of both chlorophyll *d* and *f* as 0.1, which must originate by estimations from other related compounds.

(vi) For chlorophyll *f*, ChatGPT 3.5 gave two results: one was the fabricated value of 0.001 to 0.003, whereas the other was ‘there is no widely accepted value’.

3.4 Questions about fictive dyes and fluorophores

A question concerning a fictive compound comprises a good test of the reliability of the chatbot. Six fictive compounds were conceived and used for questions with each of the six chatbots examined herein. The responses for non-existing fictive compounds from chatbots are summarized in Table 6. In general, ChatGPT 3.5 and 4o were susceptible to the fictive compounds, Gemini and Gemini advanced were reasonably careful, whereas Copilot and Meta AI were cautious. The questions (Q1–Q6) are listed below followed by additional information concerning the results. The responses can be categorized in one of several ways: (1) numbers are provided that do not exist in the context that is queried, which is referred to by the established term “fabricated”; (2) the responses indicate mis-identification of the fictive compound

Table 6 The responses to the questions about fictive dyes and fluorophores from chatbots

	ChatGPT 3.5	ChatGPT 4o	Copilot	Gemini	Gemini advanced	Meta AI
Q1	Fabricated	Fabricated	Faithful	Fabricated	Faithful	Faithful
Q2	Fabricated	Feigned	Faithful	Faithful	Feigned	Faithful
Q3	Feigned	Faithful	Faithful	Faithful	Faithful	Faithful
Q4	Fabricated	Faithful	Feigned	Faithful	Foiled	Foiled
Q5	Fabricated	Fabricated	Faithful	Fabricated	Faithful	Faithful
Q6	Faithful	Fabricated	Faithful	Faithful	Faithful	Faithful

but no data are returned, which is referred to here as “fooled”; and (3) the responses are as if the fictive compound is real but no data are provided, which is referred to here as “feigned” and is tantamount to a confidence game where there is a superficial appearance of knowledge but nothing beneath, in other words the trickery is only by half; and (4) the responses are that the compound is not known or is not available, which is an undecieved report and here is referred to as “faithful”.

(Q1) 10,10-Diphenylanthracene: Gemini regarded 10,10-diphenylanthracene as equal to 9,10-diphenylanthracene. Copilot, Gemini advanced, and Meta AI apprised that data for 10,10-diphenylanthracene were not readily available. No chatbots pointed out that the 10,10-diphenyl substitution is chemically wrong and that 10,10-diphenylanthracene is a non-existent compound.

(Q2) Coumarin 808: ChatGPT 3.5 and 4o presumed that coumarin 808 is a known coumarin derivative (which is a typical behavior of ChatGPT) and provided values similar to those of other coumarin derivatives. Gemini advanced reported that “coumarin 808 absorbs light in the near-infrared range,” most likely due to the beguiling number of 808. Such a labeling scheme is common, as exemplified by commercial dyes (*e.g.*, DyLight 800).

(Q3) Chlorophyll *k*: ChatGPT 3.5 defined chlorophyll *k* as a recently discovered pigment; otherwise, all other chatbots skipped this booby trap.

(Q4) Lucifer Red: ChatGPT 4o declared that Lucifer Red is not readily available. Copilot regarded Lucifer Red as a compound similar to that of Lucifer Yellow, but did not fabricate any data. Gemini stated that “There isn’t a well-established fluorophore called “Lucifer Red.” On the other hand, Gemini advanced concluded that Lucifer Red is a red-emitting luciferin analog used in bioluminescence imaging. Meta AI deduced that Lucifer Red is a derivative of rhodamine (Lucifer Yellow is an amino-naphthalimide derivative).

(Q5) Rhodamine 7G: ChatGPT 3.5, ChatGPT 4o, and Gemini regarded rhodamine 7G as a synonym of other rhodamine

derivatives. Conversely, Copilot, Gemini advanced, and Meta AI recognized that rhodamine 7G is a non-existing fluorophore.

(Q6) Alexa Fluor 850: all chatbots other than ChatGPT 4o clearly discerned that Alexa Fluor 850 is not a valid dye and does not exist.

Again, the intention for giving these tricky questions was not meant to cheat or depreciate the value of chatbots, but rather to show the consequences and capabilities even with zero-shot prompts. By adding (i) appropriate additional prompts (*e.g.*, if you cannot find the relevant information, please say “I don’t know”) or (ii) using few-shot prompts (first ask if the titled compounds exist or not, then provide additional questions), chatbots should be able to respond honestly.

3.5 Retrieval of absorption and fluorescence spectral traces

The capability of chatbots for retrieval of absorption and fluorescence spectral traces was examined next. Questions Q7–Q9 concerned the spectra for beta-carotene, tetraphenylporphyrin (TPP), and chlorophyll *a*, respectively. The results are provided in Table 7.

ChatGPT 3.5 tried to display absorption and fluorescence spectra by ASCII art, yet the generated graphics were nonsensical and unsatisfactory. ChatGPT 4o created spectral traces by applying a Gaussian distribution, which was a good upgrade from that of ChatGPT 3.5. Nonetheless, the spectra were of limited use due to lack of information such as the full-width-at-half-maximum (fwhm), the intensity ratio of each peak, and the inclusion of multiple peaks. Copilot and Meta AI lack capabilities for drawing spectra in graphics. Gemini and Gemini advanced pulled out the corresponding spectra in graphical form together with web links of sources, a function equivalent to that of a Google image search.

Question 10 requested the spectral overlap integral derived from the absorption spectrum of Nile Blue and the fluorescence spectrum of fluorescein. Such an overlap entails the unusual reverse FRET – in other words, uphill energy transfer from

Table 7 The responses to the questions involving spectral graphics from chatbots

	ChatGPT 3.5	ChatGPT 4o	Copilot	Gemini	Gemini advanced	Meta AI
Q7	ASCII art	Gaussian	—	Spectrum	Spectrum	Tabulated
Q8	ASCII art	Gaussian	—	Spectrum	Spectrum	Tabulated
Q9	ASCII art	Gaussian	—	Spectrum	Spectrum	Tabulated
Q10	—	Gaussian	—	—	Spectra (false)	Tabulated

fluorescein to Nile Blue. The question is demanding by requiring immensely specific data that may be neither published nor available. No chatbot could provide a suitable response. The attempt by Gemini advanced displayed the homo overlap of the absorption and fluorescence spectra of rhodamine 6G, and hence was a failure.

3.6 Perspective on methods and results

The work described herein represents the evaluation of six chatbots for performance in response to granular questions in the photosciences. As the development of AI is a rapidly evolving field, clarity and perspective are warranted concerning the methods employed for this particular study. The following points are germane.

(1) It is known that Gemini, Meta AI, and Copilot leverage both search engine results and LLMs (thereby accessing a wide range of literature), whereas GPT 3.5 and GPT 4o rely solely on their training data. An alternative means of comparison could rely on use of an application programming interface (API), which enables local operation of the chatbots independent from servers.⁸⁹ Accessing chatbots *via* an API can automate tasks by batch processing, which is an efficient approach compared to that of a web user interface (WUI), which is time consuming given the reliance on manual input.^{90,91} Similar accuracy rates were typically obtained by both WUI and API approaches for GPT-4V,⁹² yet the processing time for data extraction from scientific graphs *via* an API can be 30 times faster than that of a WUI.⁹² With speed comes cost, however: an API can cost ~ 6 times more (\$125 per month) than a WUI (\$20 per month).⁹² The tasks examined herein were relatively simple given that limited numbers of photophysical parameters were examined; thus, WUI-based chatbots were employed. Data extraction in bulk upon submitting questions concerning photophysical parameters may enjoy benefits from use of an API in the future.

(2) Chatbots are known to generate different answers when the identical question is repeated.^{93,94} An identical question was fed to GPT 4.1 for three subjects five times (see the ESI†). For those photophysical parameter retrieval tasks that are relatively straightforward, almost identical responses were obtained. Thus, each question was asked only once thereafter.

(3) Chatbots are known to be sensitive to how a prompt is formulated.⁹⁴ A prompt can be engineered to improve the quality of the responses from chatbots without tedious fine-tuning of the training data.⁹⁵ For example, repeatedly modifying the questions can engender responses in a desired format.⁹⁶ Examples in this domain include adding conditions, pinpointing solvents, indicating the environment (pH, bound to protein), limiting the phase (solid or liquid or gas), specifying the composition (*e.g.*, molecules), and so forth.

(4) During the preparation and review of this manuscript, a new version of ChatGPT (GPT 4.1) was released. Are the results presented herein already out of date? Some domain specific tasks may enjoy greater benefits due to the features of GPT 4.1; however, a foray using GPT 4.1 revealed little improvement for the retrieval of values for ϵ and Φ_f . The results are summarized

in the ESI (Tables S1 and S2†). GPT 4.1 is not immune to questions involving fictive dyes and fluorophores. GPT 4.1 does exhibit notable improvements for the graphical display of spectra, albeit utilizing Gaussian distributions.

4. Outlook

Searching the scientific literature for specific granular data as well as spectra has been a surprisingly difficult task. Said differently, it is very hard to glean from the immense scientific literature – estimated at $>10^8$ publications¹² – those specific papers wherein a spectrum or quantitative parameter is located. The difficulty has severely crimped the ability to assemble curated databases of spectra, as in PhotochemCAD, with which we have had direct experience for nearly 40 years. The advent of conversational AI chatbots, made possible by transformer-based large language models, offers potential advances in finding such information. While the potential impact of chatbots on creativity in science remains unclear, merely improved information acquisition is expected to constitute a substantial benefit.

It is clear that the present chatbots are of limited reliability for tasks that require broad processing, such as unguided education in the photosciences.⁹⁷ The results shown in Fig. 5 herein and in the accompanying text substantiate this conclusion. On the other hand, extant chatbots are of significant benefit already for punctate and singular tasks such as identification of the values of photophysical parameters that otherwise are often buried deeply in the vast scientific literature.

What is the significant difference between chatbots and extant search engines? Chatbots provide clear-cut definitive answers (a double-edged sword), which can save time and accelerate acquisition of desired information; in this regard, chatbots surpass present search engines in terms of efficiency. Chatbots do not generate novel data from scratch, but create sentences by simply adding the most suited words by following natural language theories utilizing trained data. The knowledge of chatbots acquired through training processes relies heavily on internet resources, causing the knowledge of chatbots to overlap heavily with web resources. Thus, the information accessible to chatbots and search engines has partial commonality. The well-deserved criticisms leveled at chatbots may reflect shortcomings that are not entirely idiosyncratic to chatbots, but rather arise from the nature of the source materials, particularly internet web resources. As an example, an erroneous value of a parameter in a textbook (due to author error or publication production error) could enter a website or scientific publication, and from the book or the latter sources be accessed by a chatbot. The thread-like lineage of such values often is frayed if not clipped. In other words, the propagation of mistakes and typographical errors across the internet may arise from decades-old (if not centuries-old), traditional printed materials, not chatbots.

Chatbots may not always provide accurate information, thus the domain-specific expert needs to inspect the answers carefully. With the spectral databases of PhotochemCAD in hand, evaluations of ϵ and Φ_f are straightforward tasks for compounds

represented therein. An outcome of the present study indicates the importance of using multiple chatbots to elicit results followed by evaluation by the domain-specific expert. Multiple chatbots are readily accessible, and others are under development. The possibility exists of course that all chatbots elicit identical, incorrect responses; however, the current study already demonstrates the diversity of responses from chatbots at least in the photosciences field. Even inaccurate or incorrect results often have subtleties that may warrant further scrutiny. In summary, the chatbots examined here are quite effective (but not universally so) for retrieval of granular data (ϵ and Φ_f) of considerable importance in the photosciences, are only marginally effective for finding spectral traces, and can be susceptible to inquiries concerning (intentionally or inadvertently) fictive compounds. Molecular design in the photosciences can make use of information beyond absorption and fluorescence spectra; for example, a database of the yield of intersystem crossing, phosphorescence spectrum, and triplet state lifetime would enable design of molecules for diverse photoprocesses.^{98–100} In sum, chatbots would appear to be in their infancy, yet if judiciously applied, already offer a valuable means for searching the scientific literature, for which new strategies are urgently required.

Data availability

All data used herein are contained in the body of the paper and the companion ESI.†
