# Improvement of performance to form syngas utilizing water and CO<sub>2</sub> over a particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>-based photocathode by surface comodification with ZnS and Ag†

Tomoaki Takayama, (1) ±a Akihide Iwase (1) §a and Akihiko Kudo (1) \*ab

Surface of a particulate- $Cu_{0.8}Ag_{0.2}GaS_2$ -based photocathode was co-modified with ZnS and Ag, resulting in improvement in the performance of the  $Cu_{0.8}Ag_{0.2}GaS_2$  photocathode for syngas ( $H_2 + CO$ ) formation through photoelectrochemical  $H_2O$  and  $CO_2$  reduction under visible light in an aqueous electrolyte. Bubbles of the syngas were visually observed over the developed Ag and ZnS-co-modified  $Cu_{0.8}Ag_{0.2}GaS_2$  photocathode at 0 V vs. RHE at the applied potential using a 300 W Xe-arc lamp ( $\lambda > 420$  nm). Based on various control experiments and characterization studies, the following two crucial factors have arisen: (1) formation of a (ZnS)-( $Cu_{0.8}Ag_{0.2}GaS_2$ ) solid-solution near the surface of  $Cu_{0.8}Ag_{0.2}GaS_2$  particles was vital for enhancing the separation of the photogenerated carriers, (2) the Ag cocatalyst loaded on the solid-solution worked as an active site for photoelectrochemical  $CO_2$  reduction. Moreover, artificial photosynthetic syngas formation using water as an electron donor under simulated sunlight without any external bias was demonstrated by combining the developed Ag/ZnS/ $Cu_{0.8}Ag_{0.2}GaS_2$  photocathode with a  $CoO_x$ -loaded BiVO<sub>4</sub> photoanode.

#### 1 Introduction

Photoelectrochemical systems which consist of a photocathode and a photoanode have been extensively studied not only for water splitting  $^{1,2}$  but also for  $\mathrm{CO}_2$  reduction  $^{3-5}$  using water as an electron donor. This is because these systems possess a potential to produce  $\mathrm{H}_2$  and  $\mathrm{CO}$  as reduction products of water and  $\mathrm{CO}_2$  separately from  $\mathrm{O}_2$  as an oxidation product of water. The mixture of  $\mathrm{H}_2$  and  $\mathrm{CO}$  is called syngas that can be used as a raw chemical for liquid fuels, lower olefines and aromatics synthesis.  $^6$  In this context, it is important to explore highly active photocathodes for syngas formation in terms of utilization of  $\mathrm{CO}_2$  and solar energy.

From the viewpoint of the construction of highly efficient photoelectrochemical cells, <sup>1,7</sup> metal sulfide photocathodes are attractive because of their narrow band gaps and positive onset

potentials for the cathodic photocurrent.8 In particular, particulate-metal-sulfide-based photocathodes are advantageous because they can easily be fabricated as compared with a thin film photocathode using a vacuum process. We have reported that a particulate solid-solution of CuGaS<sub>2</sub> and AgGaS<sub>2</sub> (e.g., Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>) provides higher photocathodic performance than that of pristine CuGaS2 in photoelectrochemical water reduction to form hydrogen under visible light.9 Moreover, the report10 that a particulate-(CuGa)0.5ZnS2-based photocathode is active for syngas formation under visible light motivated us to use a particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>-based photocathode for syngas formation. However, the photoelectrochemical performance of such a particulate-based photocathode is generally not yet enough to build photoelectrochemical cells that work under solar light if modifications such as loading cocatalysts are not performed. Therefore, it is important to discover a surface modification method being effective for improving the performance of Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> in order to apply Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> to a photocathode for syngas formation utilizing water and CO2 under sunlight.

Various surface modifications of photocathodes have been investigated to develop highly active photocathodes. To date, Cu<sub>2</sub>ZnSnS<sub>4</sub>,<sup>11,12</sup> Cu<sub>2</sub>ZnGeS<sub>4</sub>,<sup>13</sup> CuInS<sub>2</sub>,<sup>14</sup> Cu(In,Ga)Se<sub>2</sub>,<sup>15</sup> *p*-InP,<sup>16,17</sup> *p*-ZnTe,<sup>18</sup> *p*-Si,<sup>19,20</sup> N-doped Ta<sub>2</sub>O<sub>5</sub>,<sup>16</sup> CuFeO<sub>2</sub>,<sup>21</sup> Cu<sub>2</sub>O,<sup>22</sup> CuGaO<sub>2</sub>,<sup>23</sup> and *p*-Fe<sub>2</sub>O<sub>3</sub> (ref. 24) have emerged to showcase their performances for CO<sub>2</sub> reduction to form CO and HCOOH in aqueous solutions under visible light irradiation, which have been

improved by surface modifications. Specifically, n-type semiconductors, metal complexes, or metal nanoparticles have been investigated as the modifications. Furthermore, judging from the progress in photoelectrochemical water splitting,  $^{1,8}$  comodification of metal sulfide photocathodes with n-type semiconductors and metallic cocatalysts is expected to bring highly efficient photocathodes for  $\rm CO_2$  reduction. This is because comodifications with n-type semiconductors and noble cocatalysts are frequently employed to enhance the separation of photogenerated electron–hole pairs and introduce active sites for water reduction.

Herein, we focused on the combination of ZnS with metallic cocatalysts as a co-modification. This is because ZnS is an n-type semiconductor being effective in improvement of syngas formation on the Cu<sub>2</sub>ZnGeS<sub>4</sub> thin film photocathode<sup>13</sup> of which the crystal structure is similar to the chalcopyrite structure of Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>. ZnS is expected to be easily formed on the surfaces of particulate-metal-sulfide-based photocathodes by a chemical deposition method.25 Additionally, the toxicity of ZnS is lower than that of CdS, which is another typical n-type semiconductor. We first investigated the effects of modification conditions to deposit ZnS over particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>based photocathodes on their photocathodic performances for CO2 reduction. Sequentially, we investigated additional modifications of the ZnS-modified photocathodes with various cocatalysts. Then, we discovered a co-modification for fabricating an active photocathode for CO2 reduction to form syngas under simulated solar light, resulting in artificial photosynthetic syngas formation upon combining the developed photocathode with a CoO<sub>x</sub>-loaded BiVO<sub>4</sub> photoanode.

#### 2 Experimental methods

## 2.1 Preparation and characterization of a particulate $\label{eq:cu_0.8} \textbf{Ag}_{0.2} \textbf{GaS}_2 \textbf{-based photocathode}$

A particulate Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocatalyst was prepared by a solid-state reaction according to a previous report.9 Starting materials Cu<sub>2</sub>S (Kojundo; 99%), Ag<sub>2</sub>S (Rare Metallic; 99.9%), and Ga<sub>2</sub>S<sub>3</sub> (Kojundo; 99.99%) were ground using an agate mortar. A 10% excess amount of Ga<sub>2</sub>S<sub>3</sub> was added to the starting materials. This Ga<sub>2</sub>S<sub>3</sub>-rich condition is effective in improving performance of Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>.9 The mixture sealed in a quartz ampoule tube after evacuation (<0.1 Pa) was heated at 1073 K for 10 h to obtain Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> powder. The obtained powder was identified to be an almost single-phase by powder X-ray diffraction (Rigaku; Miniflex, X-ray source; Cu Ka). Diffuse reflectance spectra of powder and photocathode samples were obtained using a UV-vis-NIR spectrometer (Jasco; UbestV-570) with an integrating sphere, and were converted to absorbance spectra from the reflection by the Kubelka-Munk function. As the reference samples,  $(ZnS)_{2x}$ - $(Cu_{0.8}Ag_{0.2}GaS_2)_x$  solid-solutions were prepared by the same procedure above. ZnS (Sigma-Aldrich, 99.99%) was used as the starting material.

A pristine particulate- $Cu_{0.8}Ag_{0.2}GaS_2$ -based photocathode was prepared by a drop-casting method. The  $Cu_{0.8}Ag_{0.2}GaS_2$  powder was dispersed in ethanol (2–8 mg mL<sup>-1</sup>). This suspension was dripped on a FTO substrate (Asahi Glass; F-doped

 $SnO_2$ ) and thereby  $Cu_{0.8}Ag_{0.2}GaS_2$  powder was accumulated on the substrate with 5 mg cm $^{-2}$ . After drying up the ethanol at room temperature, the accumulated powder was annealed at 773 K for 2 h in  $N_2$  gas to obtain a pristine particulate- $Cu_{0.8}$ - $Ag_{0.2}GaS_2$ -based photocathode.

Modification of the pristine particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>-based photocathode (denoted as CAGS) with ZnS was conducted by a chemical bath deposition method according to the literature.25 The notation of the photocathodes prepared under different conditions is summarized in Table 1. The detailed procedures of the experiments are explained as follows. ZnSO<sub>4</sub>·7H<sub>2</sub>O (Wako; 99.5%), thiourea (Wako; 98.0%) and citric acid (Wako; 98.0%) employed as the starting materials were dissolved in 270 mL of water at 353 K at concentrations of 0.033, 0.066 and 0.088 mol L<sup>-1</sup>, respectively. After adding 30 mL of 25% of an aqueous ammonia solution (Wako) into the aqueous solution, a pristine particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>-based photocathode was immediately immersed into the final mixture for 10 minutes to deposit ZnS on the surface of the pristine photocathode. The ZnS-modified particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>-based photocathode was dried at room temperature and sequentially was annealed at 473 or 773 K for 2 h in N2 gas. These are denoted as ZnS(473)-CAGS and ZnS(773)-CAGS. Then, the ZnSmodified particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>-based photocathode with non-annealing is denoted as ZnS(NA)-CAGS. A ZnSO<sub>4</sub>-adsorbed particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>-based photocathode was prepared by dipping the pristine photocathode into an aqueous solution dissolving only ZnSO<sub>4</sub>, followed by annealing at 773 K for 2 h under a N<sub>2</sub> gas. The obtained sample is denoted as ZnSO<sub>4</sub>(773)-CAGS. The ZnSO<sub>4</sub>-adsorbed Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode with non-annealing is denoted as ZnSO<sub>4</sub>(NA)-CAGS. A CAGS photocathode was dipped into the mixture of thiourea, citric acid and an aqueous ammonia solution (namely, without ZnSO<sub>4</sub>) and then was annealed at 773 K for 2 h under N2 gas. The obtained sample is denoted as ZnSO<sub>4</sub>-w/o-CAGS. If a Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode was immersed in an aqueous solution containing either thiourea, citric acid or an aqueous ammonia solution followed by annealing at 773 K for 2 h, the obtained photoelectrodes are denoted as thiourea(773)-CAGS, citric acid(773)-CAGS and ammonia(773)-CAGS, respectively.

Cocatalysts were loaded on the surfaces of photocathodes. AgNO<sub>3</sub>, Cu(NO<sub>3</sub>)<sub>2</sub>, HAuCl<sub>4</sub>, H<sub>2</sub>PtCl<sub>6</sub>, RuCl<sub>3</sub> and RhCl<sub>3</sub> were employed as the cocatalyst sources. An aqueous solution containing either one of the cocatalyst sources was dripped on a photocathode. The amount of the loaded cocatalyst was 100 nmol cm<sup>-2</sup>. After drying off the aqueous solvent at room temperature, the photocathode was annealed at 773 K for 2 h in N<sub>2</sub> gas. Since it has been reported that RuCl<sub>3</sub> loaded on the surface of the Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode through annealing in N2 gas is reduced to metallic Ru by cathodic photocurrent during photoelectrochemical H2 formation in an aqueous solution,9 various metal cocatalyst sources were loaded on the ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode through the same procedure as that of the literature9 and could be reduced to the metallic state during the CO<sub>2</sub> reduction in our experiments. If necessary, the photocathode was immersed in a mixture of water and acetone (the ratio of 1:1 as volumes) for about 30 seconds

before dropping the aqueous solution containing the cocatalyst source in order to remove its water-repellency. Photocathode samples were analyzed using an X-ray photoelectron spectrometer (JEOL; JSP-9010MC; Mg anode). The binding energies of X-ray photoelectron spectra were corrected with the C 1s (284.3 eV) contamination peak on metallic Au foil. The binding energy of the Au foil was corrected using the reference datum of Au foil (Au 4f<sub>7/2</sub>: 84.0 eV)<sup>26</sup> after a contamination and the oxide phase on the surface of the Au foil was carefully removed by Ar etching.

#### 2.2 Photoelectrochemical measurement

Photoelectrochemical properties were evaluated using a potentiostat (Hokuto Denko; HSV-110). An H-type glass cell that consists of a working electrode cell and a counter electrode cell with a Nafion membrane (Dupont) to separate the compartment was used. A Pt wire and a saturated Ag/AgCl electrode (DKK-TOA) were used as counter and reference electrodes, respectively. 0.1 mol L<sup>-1</sup> of K<sub>2</sub>SO<sub>4</sub> aq. with a phosphate buffer (each  $0.025 \text{ mol } L^{-1} \text{ of } KH_2PO_4 \text{ aq.}$  and  $Na_2HPO_4 \text{ aq.}$ ) (pH 7) and  $0.1 \text{ mol } L^{-1} \text{ of KHCO}_3$  aq. were employed as aqueous electrolytes, respectively. The electrolyte in the H-type glass cell was saturated with 1 atm of Ar, N<sub>2</sub> or CO<sub>2</sub> before measurements. pH of the aqueous KHCO<sub>3</sub> solution saturated with CO<sub>2</sub> was ca. 7. A 300 W Xe-arc lamp was employed as a light source. The wavelength of the irradiation light was controlled by a cut-off filter, an NIR-absorbing filter and band-pass filters. A solar simulator was employed as a light source of simulated sunlight (AM1.5G). The photocathode was irradiated with the light from the FTO side. The gaseous products were determined using gas chromatographs (Shimadzu; TCD, MS-5A, Ar and He carriers, detection of H2 and O2; FID with a methanizer, MS-13X, N2 carrier, detection of CO). Formic acid was analyzed using an ion-chromatograph (TOSOH, IC-2000). An isotope experiment was conducted using <sup>13</sup>CO<sub>2</sub> to confirm the carbon source of the product of the CO<sub>2</sub> reduction. <sup>13</sup>CO of the reduction product of <sup>13</sup>CO<sub>2</sub> was analyzed using GC-MS (Shimadzu; GCMS-QP2010 Plus, RESTEK; RT-Msieve 5A). For photoelectrochemical measurement using a two-electrode-type cell, the photocathode (3.3 cm<sup>2</sup>) was irradiated from the FTO side with the simulated

sunlight through a photoanode (1.0 cm<sup>2</sup>), resulting in that the total irradiation area was 3.3 cm<sup>2</sup>.

#### 3 Results and discussion

#### Surface modification with ZnS

Fig. 1 shows the effect of modification with ZnS on the photoelectrochemical properties of a particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>based photocathode in an aqueous K2SO4 solution with a phosphate buffer (pH 7) saturated with 1 atm of N2 gas under visible light irradiation. A pristine particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>based photocathode gave a cathodic photocurrent under visible light irradiation as observed in a previous report (Fig. 1(a)).9 The cathodic photocurrent was increased by modification with ZnS on the surface of the particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>-based photocathode by chemical bath deposition (CBD) (Fig. 1(b)). The onset potentials of the linear sweep voltammograms were affected by the difference in the CBD conditions (Fig. S1†), though it was difficult to find the relationship between the onset positions and the CBD conditions. Onsets of action spectra of the ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathodes almost agreed with the absorption edge of pristine Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> powder (Fig. 2), indicating that the cathodic photocurrent was generated by the

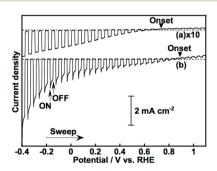

Fig. 1 Linear sweep voltammograms of (a) pristine and (b) ZnSmodified particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>-based photocathodes under visible light irradiation. Electrolyte: 0.1 mol  $L^{-1}$  of an aqueous  $K_2SO_4$ solution with a phosphate buffer (pH 7) saturated with 1 atm of  $N_2$  gas, light source: a 300 W Xe-arc lamp with a cut-off filter ( $\lambda > 420$  nm).

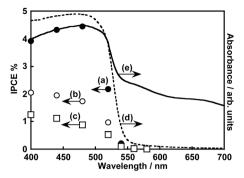

Fig. 2 Action spectra of ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathodes at (a) -0.4, (b) 0 and (c) 0.3 V vs. RHE and diffuse reflectance spectra of (d) pristine  $Cu_{0.8}Ag_{0.2}GaS_2$  powder and (e) the  $ZnS/Cu_{0.8}Ag_{0.2}GaS_2$ photocathode. Electrolyte: 0.1 mol L<sup>-1</sup> of an aqueous K<sub>2</sub>SO<sub>4</sub> solution with a phosphate buffer (pH 7) saturated with 1 atm of N2 gas, light source: a 300 W Xe-arc lamp with band-pass filters.

band gap excitation of Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>. Fig. 3 shows the time course of the photoelectrochemical H<sub>2</sub> formation using the ZnS/ Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode. Although the photocurrent density was fairly high in the initial period (Fig. 3(a)), the value decreased with reaction time (Fig. 3(b)). This deactivation in the initial period could be attributed to the elution of the ZnS similar to the CdS deposited on chalcogenide photocathodes.12,27,28 The observed photocurrent of the ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>-GaS<sub>2</sub> in the later period almost corresponded to the H<sub>2</sub> evolution rates under visible light, indicating that the faradaic efficiency was almost 100% (Fig. 3(b)). In order to clarify the experimental factor affecting the H2 formation rate over a ZnSmodified Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode, control experiments were performed (Table 1). The annealing procedure after the ZnS modification with CBD was effective in improving the photocurrent density, while the photocurrent density of the pristine one was slightly enhanced by ZnS modification without annealing (Table 1, entries 1-4). Among them, annealing at 773 K was the most effective here. This is because, considering the heat resistance of FTO glass substrates, 773 K is close to the limit temperature. In contrast, significant improvement was not observed in the absence of ZnSO<sub>4</sub> in the starting materials for CBD with annealing at 773 K (Table 1, entries 5-8). The

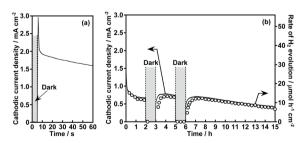

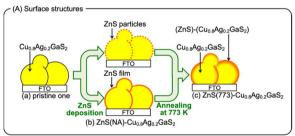

Fig. 3 Photoelectrochemical H<sub>2</sub> evolution using a ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>-GaS<sub>2</sub> photocathode under visible light irradiation in (a) the initial and (b) the whole period of the reaction time. Electrolyte:  $0.1 \text{ mol } L^{-1}$  of an aqueous K<sub>2</sub>SO<sub>4</sub> solution with a phosphate buffer (pH 7) saturated with 1 atm of Ar gas, light source: a 300 W Xe-arc lamp with a cut-off filter (λ > 420 nm), applied potential: 0 V vs. RHE.

photocurrent density of a ZnSO<sub>4</sub>-modified Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode was larger than that of the pristine one (Table 1, entry 9). Thus, the cathodic photocurrent of Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> was significantly improved when all of ZnSO<sub>4</sub>, thiourea, citric acid and ammonia were used for CDB with annealing at 773 K.

The surface configuration of the ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode was examined using X-ray photoelectron spectra (XPS), Auger spectra and additional control experiments. Auger spectra indicated that the deposited ZnS partly included ZnO and Zn(OH)<sub>2</sub> (Fig. S2†). The ZnO and Zn(OH)<sub>2</sub> still existed at the surface even after annealing at 473 K. Such auger spectra disappeared after annealing at 773 K. Moreover, intensities of Zn 2p XPS peaks decreased with the increase in the annealing temperature, and annealing at 773 K drastically decreased the intensities (Fig. S3†). These auger and XPS measurements indicated the following two points; (i) deposited ZnS including ZnO and Zn(OH)<sub>2</sub> existed at the surface of ZnS(473)-CAGS, (ii) deposited Zn species were diffused in the surface of Cuo 8-Ag<sub>0.2</sub>GaS<sub>2</sub> particles in ZnS(773)-CAGS. In other words, an annealing at 773 K is crucial to diffuse the ZnS deposited on the Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> particles into the neighbourhood in the surface of the Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> particles as summarized in Fig. 4(A). Specifically, the surface of the Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> particles was covered with ZnS either of particles or film (Fig. 4(A)(a) and (b)). Afterwards, the ZnS was diffused into the Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> particles by annealing at 773 K, though almost all of the ZnS existed in the neighbourhood in the surface (Fig. 4(A)(c)). This diffusion made the solid-solution of (ZnS)-(Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>) in the neighbourhood in the surface. The concentration of the diffused ZnS was gradually diluted from the surface to the bulk. Therefore, a crucial factor of the improvement was formation of

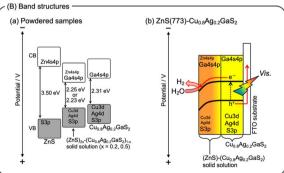

Fig. 4 (A) Proposed surface structures of the particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>-GaS2-based photocathode, and (B) proposed band structures of  $(ZnS)_{2x}$ - $(Cu_{0.8}Ag_{0.2}GaS_2)_x$  powders and the ZnS(773)- $Cu_{0.8}Ag_{0.2}GaS_2$ photocathode. The band gaps were estimated from the adsorption edges shown in Fig. S4.†

the (ZnS)-(Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>) solid-solution in the neighbourhood in the particulate Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> surface. This crucial factor could provide the following effects. The surface incorporated with ZnS could work as an active site for photoelectrochemical water reduction, since ZnS is a well-known active photocatalyst for H<sub>2</sub> formation without loading of cocatalysts.<sup>29-32</sup> Another aspect of the improvement may lie in the gradient of the band structure as shown in Fig. 4(B). The band gap of powdered Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> was narrowed by forming the solid-solution of powdered (ZnS)–( $Cu_{0.8}Ag_{0.2}GaS_2$ ) (Fig. S4†). The phenomenon to narrow the band gaps by homogeneously mixing with ZnS has been reported in the case of the (ZnS)-(CuGaS<sub>2</sub>) solid-solution (namely, no Ag constituent).<sup>33</sup> These narrowed band gaps could be explained by the increase in the symmetries of  $MS_4$  tetrahedrons (M = Zn, Cu, and Ga), implying that the conduction band minimum and valence band maximum both are shifted downwardly.33 Again, XRD spectra of the (ZnS)-(Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>) (Fig. S4†) show that the MS<sub>4</sub> tetrahedrons (M = Zn, Cu, Ag, and Ga) tended to be close to the symmetrical tetrahedrons, judging from the peak splitting. Therefore, the conduction band minimum and valence band maximum of powdered (ZnS)-(Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>) might be located at more positive potentials than those of Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> (Fig. 4(B)(a)). As for the structural information, no morphological changes in a series of ZnS-modified Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> were observed using a scanning electron microscope (SEM), though it was difficult to clarify the structural configurations of the deposited ZnS in the observations using a SEM equipped with an energy dispersive X-ray spectrometer (SEM-EDS) (Fig. S5†). Although the quantitative consistency of the ZnS ratios between the photocathode and the powders was unclear, the aforementioned effect to alter the band positions implied that the conduction band minimum and valence band maximum of the neighbourhood in the surface gradually shifted downwardly due to the concentration gradient of the solid-solution of  $ZnS(773)-Cu_{0.8}Ag_{0.2}GaS_2$  (Fig. 4(B)(b)). Assuming that the absorption coefficient of (ZnS)-(Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>) is similar to that of CuGaS<sub>2</sub> in the visible light region (20 000-50 000 cm<sup>-1</sup>),<sup>34</sup> the ZnS-modified Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> particles near FTO were mainly photoexcited. This is because the transmittance of incident photons would be at least 0.01% when the diameters of ZnS(773)-modified Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> particles were ca. 2 μm (Fig. S5†). Indeed, we reported that CuGaS<sub>2</sub> particles being far from FTO have little contribution to the photocurrents of particulate-CuGaS2-based photocathodes.35,36 Finally, the photogenerated electrons migrated to the surface region by the band bending of the ZnS-modified Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> particles, resulting in enhancement of the separation of the photogenerated carriers (Fig. 4(B)(b)). These two aspects could be the crucial factors for the improvement by the ZnS modification.

#### 3.2 Effect of cocatalysts loaded over ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathodes on CO<sub>2</sub> reduction performances

Table 2 shows the application of the ZnS(773)-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode (denoted as ZnS/Cu $_{0.8}$ Ag $_{0.2}$ GaS $_2$ , hereafter) to CO $_2$ reduction under visible light and the effects of additional

modification of ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathodes with various cocatalysts. In this measurement, an aqueous KHCO3 solution saturated with 1 atm of CO<sub>2</sub> gas (pH was ca. 7) was used as an electrolyte and 0 V vs. RHE was constantly applied to the photocathodes. Again, the pristine particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>based photocathode gave a cathodic photocurrent in the aqueous KHCO<sub>3</sub> electrolyte (Table 2, entry 1). Partial cathodic photocurrent densities  $(I_{partial})$  for  $H_2$  and CO formations were certainly estimated. The surface modification with ZnS was effective for improving both  $J_{\text{partial}}$  and  $\text{FE}_{\text{CO}}$  (Table 2, entry 2). Considering the literature about photoelectrochemical CO2 reduction to form CO over surfaces of (CuGa)<sub>0.5</sub>ZnS<sub>2</sub> (ref. 10) and ZnS-modified Cu<sub>2</sub>ZnGeS<sub>4</sub> (ref. 13) photocathodes, the surface of ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> seems to be effective for CO formation. No cathodic photocurrents for H<sub>2</sub> and CO formation were observed under darkness (Table 2, entry 3). In an aqueous K<sub>2</sub>SO<sub>4</sub> solution with a phosphate buffer (pH 7) saturated with 1 atm of N<sub>2</sub> gas under visible light irradiation instead of the KHCO<sub>3</sub> electrolyte, photocurrent density only for H<sub>2</sub> formation was observed (Table 2, entry 4). Various cocatalysts were further loaded on the surfaces of the ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathodes (Table 2, entries 5-13). Noble metal cocatalysts of Pt, Rh and Ru were not effective for CO<sub>2</sub> reduction (Table 2, entries 5-7). Although the faradaic efficiencies of Pt- and Ru-loaded ones were beyond 100%, this is most likely because of experimental errors associated with usage of a syringe (1 mL) to extract the gaseous products. Au, Cu and Ag cocatalysts improved the partial current densities not only for H<sub>2</sub> formation but also for CO formation (Table 2, entries 8-10). The Ag-loaded ZnS/ Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> (Ag/ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>) photocathode showed the highest partial cathodic photocurrent densities for H<sub>2</sub> and CO formation. This sufficient performance was only obtained when the surface was modified with both ZnS and Ag accompanied by annealing (Table 2, entries 10-13). Considering the following three insights: (1) RuCl<sub>3</sub> loaded on the surface of the Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode through annealing in N<sub>2</sub> gas is reduced to metallic Ru by cathodic photocurrent during photoelectrochemical H<sub>2</sub> formation in an aqueous solution, (2) In<sub>2</sub>S<sub>3</sub> modified on a Cu<sub>2</sub>ZnSnS<sub>4</sub> photocathode is reduced to metallic In during the photoelectrochemical reduction reaction,12 (3) powdered Ag-containing metal sulfide photocatalysts with high apparent quantum yield for H<sub>2</sub> formation may reduce silver sulfide to metallic Ag during H<sub>2</sub> formation in an aqueous solution, 37,38 it was suggested that the cathodic photocurrent was partly used to reduce the silver species loaded on the surface to metallic silver at the beginning stage. This metallic silver could be electrochemically active for CO2 reduction as reported in the literature about an Ag metal electrode. 39,40 The bubbles mixed with H<sub>2</sub> and CO gases were visually generated on the Ag/ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode accompanied by O<sub>2</sub> production on a Pt counter electrode when 0 V vs. RHE was applied to the photocathode under visible light irradiation (see an attached movie file). The Ag/ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode was active even under simulated sunlight (Fig. 5). An isotope experiment using <sup>13</sup>CO<sub>2</sub> was conducted to confirm the carbon source of CO obtained. An aqueous K2SO4 solution saturated with 1 atm of 13CO2 was employed as the electrolyte

Table 2 Effects of various surface modifications of particulate Cu<sub>0.8</sub>Aq<sub>0.2</sub>GaS<sub>2</sub>-based photocathodes on photoelectrochemical CO<sub>2</sub> reduction under visible light<sup>a</sup>

(Fig. S6†). Not <sup>12</sup>CO but <sup>13</sup>CO was obtained as the reduction product of <sup>13</sup>CO<sub>2</sub> over the Ag/ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode, indicating that the carbon source of the obtained CO was a CO<sub>2</sub> molecule. When Ag, Cu and Au cocatalysts were employed, a small amount of formic acid was detected but it was difficult to quantify the formic acid. Thus, co-modification with ZnS and Ag using annealing has arisen as a new effective technique for improving the performance of the particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>based photocathode for the CO<sub>2</sub> reduction to form CO accompanied by H2 formation in an aqueous solution under simulated sunlight.

Fig. 6 shows CO<sub>2</sub> reduction using a photoelectrochemical cell consisting of a Ag/ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode and a CoOx/BiVO4 photoanode41 in an aqueous KHCO3 solution saturated with 1 atm of CO<sub>2</sub> gas. This photoelectrochemical cell of which the structure was partly a tandem-type gave photocurrent under simulated sunlight irradiation without any external bias. This is due to an overlap between onset potentials of the photocathode and the photoanode in the CO<sub>2</sub>-saturated KHCO<sub>3</sub> electrolyte, as shown in Fig. 7. Considering that the

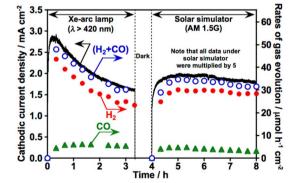

Fig. 5 Photoelectrochemical  $CO_2$  reduction using the Ag/ZnS/ Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode under visible light and simulated sunlight irradiation. Electrolyte: 0.1 mol L<sup>-1</sup> of an aqueous KHCO<sub>3</sub> solution saturated with 1 atm of CO<sub>2</sub> gas, light source: a 300 W Xe-arc lamp with a cut-off filter ( $\lambda > 420$  nm) and a solar simulator (AM1.5G), applied potential: 0 V vs. RHE. All of the observed current and the production rates under simulated solar light were multiplied by 5 for ease of the discussion of the performances.

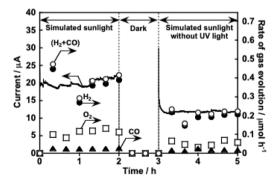

Fig. 6 CO<sub>2</sub> reduction utilizing water as an electron donor using a photoelectrochemical cell consisting of an Ag/ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode and a CoO<sub>x</sub>/BiVO<sub>4</sub> photoanode under simulated sunlight without any external bias. Electrolyte: 0.1 mol L<sup>-1</sup> of an aqueous KHCO3 solution saturated with 1 atm of a CO2 gas, light source: a solar simulator (AM1.5G) without/with a cut-off filter ( $\lambda > 420$ nm), area of electrodes:  $Ag/ZnS/Cu_{0.8}Ag_{0.2}GaS_2$  photocathode; 3.3 cm<sup>2</sup> and CoO<sub>x</sub>/BiVO<sub>4</sub> photoanode; 1.0 cm<sup>2</sup>.

<sup>&</sup>lt;sup>a</sup> Electrolyte: 0.1 mol L<sup>-1</sup> of an aqueous KHCO<sub>3</sub> solution saturated with 1 atm of CO<sub>2</sub> gas (pH was ca. 7), light source: a 300 W Xe-arc lamp with a cutoff filter ( $\lambda > 420$  nm), applied potential: 0 V vs. RHE, reactor: a closed H-type glass cell (namely, a batch-type reactor).  $J_{\text{partial}}$  indicates an average of a partial cathodic photocurrent density for 3 h. For quantification of the gaseous products, a syringe (1 mL) was used to extract the gas. <sup>b</sup> Annealing was performed under a N<sub>2</sub> atmosphere for loading cocatalysts. FE<sub>CO</sub> = (sum of the number of electrons consumed for CO formation)/(sum of the  $number\ of\ electrons\ passing\ through\ the\ outer\ circuit)\times 100.\ FE_{total} = (sum\ of\ the\ number\ of\ electrons\ consumed\ for\ H_2\ and\ CO\ formation)/(sum\ of\ electrons\ consumed\ for\ H_2\ and\ CO\ formation)/(sum\ of\ electrons\ consumed\ for\ H_2\ and\ CO\ formation)/(sum\ of\ electrons\ consumed\ for\ H_2\ and\ electrons\ electrons\ consumed\ for\ H_2\ and\ electrons\ electron$ the number of electrons passing through the outer circuit)  $\times$  100.

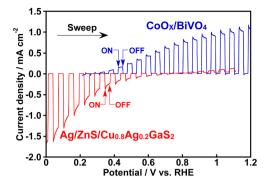

Fig. 7 Linear sweep voltammograms of an Ag/ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode and a CoO<sub>x</sub>/BiVO<sub>4</sub> photoanode under visible light irradiation. Electrolyte: in 0.1 mol L<sup>-1</sup> of an aqueous KHCO<sub>3</sub> solution saturated with 1 atm of a CO<sub>2</sub> gas, light source: a 300 W Xe-arc lamp with a cut-off filter ( $\lambda > 420$  nm).

absorption coefficient of BiVO<sub>4</sub> at 420 nm is 67 000 cm<sup>-1</sup>, 42 1% of the incident photons could arrive at the Ag/ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>-GaS2 photocathode when the thickness of our BiVO4 was regarded to be similar to the literature (ca. 300 nm).41 The faradaic efficiency for CO formation using the Ag/ZnS/Cu<sub>0.8</sub>-Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode was ca. 20% regardless of the decrease in the incident photons and change in the applied potentials (Table S1†). Therefore, the cell of which the structure was partly a tandem-type would hardly affect the selectivity for syngas formation. By paying attention to Fig. 6 again, observed photocurrent almost corresponded to the summation of CO and H<sub>2</sub> formation in the cathode cell, indicating that the photocurrent was used for syngas formation through photoelectrochemical reduction of water and CO<sub>2</sub>. Most importantly, O2 of the oxidation product of water was certainly obtained in the anode cell, whereas the rate of O<sub>2</sub> formation was slightly less than the stoichiometry due to an experimental error with the lower photocurrent. The photocurrent was continuously observed even under visible light included in simulated sunlight without any external bias. This indicated that this cell possessed an ability to utilize the visible light of sunlight. Thus, we successfully demonstrated solar syngas formation through the reduction of water and CO<sub>2</sub> separately from O<sub>2</sub> of the oxidation product of water upon constructing the photoelectrochemical cell consisting of the developed Ag/ZnS/Cu<sub>0.8</sub>-Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode and the CoO<sub>x</sub>/BiVO<sub>4</sub> photoanode.

#### Conclusions

A co-modification with ZnS and Ag has been developed for improvement in H<sub>2</sub>O and CO<sub>2</sub> reduction over a particulate-Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub>-based photocathode to form H<sub>2</sub> and CO under visible light in an aqueous electrolyte. The faradaic efficiency and the partial cathodic photocurrent density for CO formation over the Ag/ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode achieved approximately 20% and 300 μA cm<sup>-2</sup>, respectively, at 0 V vs. RHE. The Ag/ZnS/Cu<sub>0.8</sub>Ag<sub>0.2</sub>GaS<sub>2</sub> photocathode was combined with a CoO<sub>x</sub>/BiVO<sub>4</sub> photoanode for constructing a photoelectrochemical cell. This photoelectrochemical cell

gave steady photocurrent under simulated sunlight irradiation without any external bias, resulting in syngas (H2 and CO) formation using water as an electron donor. The knowledge in this work is expected to contribute to development of new particulate-photocatalyst-based photocathodes for highly efficient syngas production under sunlight.
