Addition of $\text{CF}_3$ across unsaturated moieties: a powerful functionalization tool

Estíbaliz Merino* and Cristina Nevado*

In the last few years, the efficient introduction of trifluoromethyl groups in organic molecules has become a major research focus. This review highlights the recent developments enabling the incorporation of $\text{CF}_3$ groups across unsaturated moieties, preferentially alkenes, and the mechanistic scenarios governing these transformations. We have specially focused on methods involving the simultaneous formation of $\text{C–CF}_3$ and $\text{C–C}$ or $\text{C–heteroatom}$ bonds by formal addition reactions across $\pi$-systems, as such difunctionalization processes hold valuable synthetic potential.

Introduction

The presence of C–F bonds in organic molecules has a profound effect on properties such as lipophilicity, permeability and metabolic stability so that more than 20% of the current approved drugs contain at least one fluorine atom.1,2 Thus, in the past few years, the efficient introduction of fluorine atoms or fluorine containing groups in pharmaceuticals, agrochemicals and functional materials has turned into a major research focus for synthetic chemists.3–10 Transition metal catalyzed trifluoromethylation reactions are the most popular route to introduce $\text{CF}_3$ groups into common building blocks, although recently, metal-free processes have also been described to carry out this transformation under alternative, and sometimes even complementary, conditions. In this context, double bonds can be considered privileged starting materials, as they are easily accessible and robust feedstocks, but are also amenable to flexible functionalization. This review highlights the recent developments enabling the incorporation of $\text{CF}_3$ groups across unsaturated moieties and the mechanistic scenarios governing these transformations. We have preferentially focused on alkenes as...
starting materials, with special attention on methods that involve the simultaneous formation of C-CF₃ and C-C or C-heteroatom bonds by formal addition reactions across π-systems.

1. Alkene trifluoromethylation

Pioneering studies describing the electrochemical hydrotrifluoromethylation of alkenes were reported in the late 80's.¹¹,¹² Aliphatic trifluoromethylated compounds could be efficiently prepared by electrochemical oxidation of trifluoroacetic acid, as TFA is one of the most economic and easily available sources of CF₃.¹³ Fumaronitrile 1 and related activated olefins were transformed into the 2-trifluoromethylsuccinyl derivatives by oxidation of trifluoroacetic acid in platinum electrodes in a mixture of acetonitrile and water at 50–55 °C (Scheme 1).¹⁴ The trifluoromethyl radicals generated in the anode recombined with the succinyl radicals produced at the cathodic site, leading to the formation of products 2.

In 2002, Langlois et al. showed the hydrotrifluoromethylation of unactivated alkenes with CF₃SO₂Na by electrochemical oxidation albeit with low chemoselectivity.¹⁵ Later, the hydrotrifluoromethylation of α,β-unsaturated ketones in the presence of RhCl(PPh₃)₃ and Et₂Zn was reported. In this reaction, CF₃I was employed as a trifluoromethyl source and α-trifluoromethylated carbonyl compounds were obtained in moderate yields.¹⁶ The authors proposed the formation of a rhodium hydride complex by reaction of RhCl(PPh₃)₃ and Et₂Zn. The oxidative addition of CF₃I occurred on the rhodium enolate, which furnished the product by reductive elimination. In contrast, the reaction of α,β-unsaturated acyl-oxazolidinones 3 in the presence of Et₃B under oxidative conditions (O₂) enabled the synthesis of chiral β-trifluoromethylated amino acids (Scheme 2).¹⁷ The proposed mechanism involves the generation of a CF₃-radical, which undergoes Michael addition to form a diethylboron enolate whose in situ hydrolysis led to the observed product 4 with complete β-regioselectivity but no diastereoselectivity.

In contrast to the previously described methods, the hydrotrifluoromethylation reaction of unactivated olefins remained, until recently, much less explored. The groups of Qing,¹⁸ Gouverneur¹⁹ and Nicewicz²⁰ described, almost simultaneously, the hydrotrifluoromethylation of unactivated alkenes. The reactions, operating under mild conditions, enabled a net “fluoroform” addition across alkenes and alkynes in a regioselective manner obtaining exclusively in most cases anti-Markovnikov regioisomers. Qing’s protocol required AgNO₃ as a catalyst, CF₃SiMe₃ as a trifluoromethylating agent and PhI(OAc)₂ as an oxidant. These conditions were amenable to monosubstituted alkenes 5 which produced trifluoromethyl alkanes 6 at room temperature (Scheme 3). Preliminary control experiments seemed to point towards the formation of CF₃ radical species under the abovementioned conditions. Upon addition of the CF₃ radical to the double bond, hydrogen is likely abstracted from 1,4-cyclohexadiene to give the observed products.

Gouverneur’s hydrotrifluoromethylation of unactivated terminal and geminally disubstituted alkenes (Scheme 4) and alkynes (Scheme 5) could also be carried out at room temperature using visible-light-activated Ru(bpy)₃Cl₂/C₆H₄NO₂, Umemoto’s reagent (7) as a CF₃ source and methanol as a hydrogen donor according to the mechanism proposed in Scheme 4.¹⁹

Nicewicz developed a metal-free photoredox process for the hydrotrifluoromethylation of unactivated mono-, di- and trisubstituted alkenes shortly thereafter.²⁰ The Langlois reagent (CF₃SO₂Na) was used as a CF₃ source and N-methyl-9-mesityl...
acridium as a photoredox catalyst. Methyl-thiosalicylate could act as a hydrogen donor in the case of aliphatic alkenes (Scheme 6) whereas thiophenol seems to be better suited for styrene substrates.

Beyond hydrotrifluoromethylation reactions, the allyl trifluoromethylation of alkenes has also received significant attention in recent years. Thus, the groups of Buchwald,21 Wang22 and Liu23 reported the allylic trifluoromethylation of unactivated olefins with copper salts and the Togni (8) or the Umemoto (7) reagent as a trifluoromethyl source. Although the exact mechanism for these transformations is yet to be elucidated, radical or cationic species generated upon CF₃ addition across the terminal double bond have been proposed as likely intermediates. Subsequent H-elimination delivers the observed products (Scheme 7).

Copper(I)-catalyzed trifluoromethylations of allylsilanes with the Togni reagent under mild conditions were also described by the groups of Sodeoka and Gouverneur.24,25 Allylic trifluoromethylated compounds 9 were obtained with 2-substituted allylsilanes as starting materials (Scheme 8). When the allylsilanes were not substituted in the 2-position, the corresponding vinyl silane derivatives 10 could be isolated in excellent selectivities and yields (Scheme 9).

2. Alkene trifluoromethylation and C–C bond formation

The simultaneous formation of C–C and C–CF₃ bonds represents an attractive strategy for the carbodifunctionalization

of alkenes. A pioneering example was reported by Liu's group in 2012. A palladium-catalyzed intramolecular oxidative aryltrifluoromethylation of activated alkenes was developed so that CF₃-substituted oxindoles 13 could be obtained in excellent yields. Upon π-activation of the olefin by the metal and cyclization with the aromatic ring, the Pd(II) intermediate was oxidized to Pd(IV) in the presence of PhI(OAc)₂. The system CsF/TMSCF₃ worked as a nucleophilic source of CF₃, triggering the ligand exchange on the Pd(IV) intermediate 12 prior to the reductive elimination, furnishing the new Csp³–CF₃ bond (Scheme 10).

Later, Sodeoka's group reported the combination of CuI and Togni reagent 8 to access trifluoromethylated oxindoles in excellent yields from similar acryylanilide starting materials. The use of Langlois' reagent (CF₃SO₂Na) and TBHP in the presence of Cu(II) in aqueous media at room temperature also furnished this type of compounds through a radical process. The recycling of the aqueous medium was possible at least 5 times with only a slight decrease in the isolated yields. A similar process but in a mixture of organic solvents was also developed.

The combination of copper salts and Togni reagent 8 enabled Sodeoka's group to synthesize trifluoromethylated carbocycles (14, Scheme 11) and heterocycles (15, Scheme 12) in the first examples of aryltrifluoromethylations on unactivated olefins. In this case, the six membered ring formation seemed to be faster than the five membered ring one, an acceleration that could be explained by a more favourable orbital interaction between the aryl ring and alkene in the transition state for the former case.

Trifluoromethylated 1,2-benzothiazinane dioxide derivatives 16 could be obtained by a similar tandem trifluoromethylation-annulation reaction with N-allyl-N-sulfonylamines as substrates also in the presence of copper and Togni reagent 8 (Scheme 13).

In the presence of catalytic amounts of copper and Togni reagent 8, 1,6-enynes 17 delivered substituted hydrofurans, tetrahydropranes, piperidines and pyrrolidines as a result of a tandem trifluoromethylation–cyclization process (Scheme 14). Upon addition of 2-iodo benzoic acid released from Togni's reagent, the triple bond seemed to work here as a nucleophile generating 5- or 6-exo-dig carbo- and heterocycles in a highly regioselective manner.

Recently, Nevado's group described an aryltrifluoromethylation of alkenes in which the reactivity of acrylamides 18 was modulated by the substituent on the nitrogen atom. N-Alkyl substituted substrates furnished trifluoromethylated oxindoles.
In 48–74% yield when \([\text{Cu(MeCN)}_4]PF_6\) was used as a catalyst and 2,2'-bipyridine as a ligand in acetonitrile at 80 °C in the presence of trifluoromethylating agent 8. In contrast, α-aryl-β-trifluoromethylamides bearing a quaternary stereocenter 20 were obtained with Cu₂O as a catalyst when an aromatic ring was attached to the nitrogen atom (Scheme 15). Both transformations could be rationalized on the basis of a mechanism involving the trifluoromethylation of the activated alkene to give an alkyl radical intermediate 21 as shown in Scheme 16. Upon cyclization with the arylsulfonyl moiety, a spirobicyclic intermediate 22 was formed. Re-aromatization accompanied by desulfonylation delivered an amidyl radical 23 which could either undergo protonation to give the corresponding amides 20 or, alternatively, form a new C(sp³)–N bond in the ortho relative position to the original sulfonyl group explaining oxindoles 19. In both processes, a copper-catalyzed one-pot trifluoromethylation, 1,4-aryl migration and desulfonylation cascade seemed thus to be operating.

The same group also described the first example of a metal-free alkene aryltrifluoromethylation. Tetrabutylammonium iodide could activate Togni reagent 8 forming highly active iodine(III) species, which seem to easily release the CF₃ group. Trifluoromethylated isoquinolinediones 24, oxindoles 19, spirocycles 25 and α-aryl-β-trifluoromethylamides 20 could be obtained by this procedure with excellent yields in a highly regioselective fashion (Scheme 17). Preliminary mechanistic studies seemed to rule out a radical mechanism for these transformations. An alternative metal-free aryltrifluoromethylation of alkenes was also recently described using inexpensive TMSCF₃, PhI(OAc)₂ and KF as additives likely involving radical intermediates.35

Interestingly, a metal-free synthesis of phenanthridines 27 from isonitriles 26 was previously described by Studer’s group using tetrabutylammonium iodide as an activator of Togni reagent 8 in a radical process (Scheme 18).36 A new phenyl ring is formed after trifluoromethylation reaction. Also Zhou’s group described the synthesis of phenanthridines by oxidative cyclization of 2-isocyanobiphenyls with PhI(OAc)₂ and CF₃SiMe₃.37

**Scheme 15** Copper-catalyzed aryltrifluoromethylation–desulfonylation cascade on acrylamides 18.

**Scheme 16** Mechanism of the copper-catalyzed aryltrifluoromethylation–desulfonylation cascade.
The trifluoromethylation of α,α-diaryl allylic alcohols 28 provided trifluoromethyl ketones 30 through a 1,2-aryl migration in intermediate 29 upon addition of a CF₃ radical to the double bond (Scheme 19). Aromatic rings bearing electron-withdrawing groups migrated preferentially over electron-rich aryl groups in line with the radical mechanism proposed for this transformation. Sodeoka’s group showed that iron acetate in the presence of base (K₂CO₃) also led to the formation of substituted trifluoromethylated carbonyl compounds starting from diaryl allyl alcohols in very good yields.  

Other interesting example that combined alkene trifluoromethylation with the formation of a new C–C bond was described by Szabo’s group. Styrenes, in the presence of CuCN as the cyanide source and bulky phosphines or B₂pin₂ as additives, delivered cyanotrifluoromethylated aromatic compounds 31 in a highly regioselective manner in a one-pot trifluoromethylation/C–C bond formation (Scheme 20). This protocol was limited to styrenes with electron-withdrawing para and ortho substituents. However, this reaction was also described with aliphatic and
ortho, meta and para-substituted aromatic substrates with good yields using Cu(OTf)$_2$ as a catalyst, 8 as a trifluoromethylating agent and TMSCN as a cyanide source.

3. Alkene trifluoromethylation and C–heteroatom bond formation

3.1 Alkene trifluoromethylation and C–O bond formation.
As discussed in Section 1, the electrooxidation of trifluoroacetic acid was an efficient way to generate CF$_3$ radicals in situ. Thus, pioneering examples of allene oxotrifluoromethylations were reported under these reaction conditions. In a representative example, the reaction of butyl acrylate, under controlled electro-oxidation conditions, furnished 4,4,4-trifluoro-2-oxobutanoate and butyl 4,4,4-trifluoro-2-hydroxybutanoate in a 2:1 ratio and 40% overall yield (Scheme 21).

The first examples of oxotrifluoromethylation in unactivated alkenes were reported by Buchwald and co-workers in 2012. Based on the [Cu(MeCN)$_4$PF$_6$/2,2'-biquinoline catalytic system and in the presence of Togni reagent 8, the intramolecular nucleophilic attack of various oxygenated species such as carboxylic acids, alcohols and phenols following trifluoromethyl addition to the double bond could be carried out. A broad array of functional groups including amides, epoxides, aryl bromides and β-lactones were compatible with the reaction conditions.

In addition, an enantioselective version of this transformation was described by the same group using (S,S)-tBuBOX as a chiral ligand for copper. The mechanistic proposal involved a metal C–O bond formation via a carbon radical intermediate as shown in Scheme 22.

Trifluoromethyl-substituted isoxazolines could also be obtained by cyclization of oximes after C–CF$_3$ bond formation using 20 mol% of CuCl and Togni’s reagent. A related protocol using CuBr and 1,10-phenanthroline-5,6-dione was described by Ma and co-workers for the efficient oxotrifluoromethylation of 2,3-allenoic acids. β-Trifluoromethylated butenolides could be obtained in moderate to high yields (Scheme 23).

The combination of copper salts and Togni reagent was also successfully applied to the oxotrifluoromethylation of styrenes and arylalkynes as reported by Szabó and co-workers. In these reactions, the 2-iodo benzoic acid generated upon transfer of the trifluoromethyl group from 8 reacted as an external nucleophile, delivering the corresponding trifluoromethylated vinyl or alkyl benzoates and styrenes.

An intermolecular oxotrifluoromethylation of alkenes was also developed taking advantage of photoredox catalysis in a three component reaction using Umemoto’s reagent 7 as a trifluoromethyl source. The reaction is highly regioselective and different O functionalities could be introduced in the styrene substrates.

An intermolecular oxotrifluoromethylation of alkenes was also developed taking advantage of photoredox catalysis in a three component reaction using Umemoto’s reagent 7 as a trifluoromethyl source. The reaction is highly regioselective and different O functionalities could be introduced in the styrene substrates.

This methodology was applied in the synthesis of panomifene 37, a compound with antiestrogenic activity used in the treatment of breast cancer (Scheme 25).
An additional three-component oxy trifluoromethylation of alkenes was reported by Qing and co-workers using hydroxyl amines, Langlois reagent (NaSO₂CF₃), tBuOOH and CuSO₄/CH₂O. This reaction is regioselective and a radical mechanism is proposed to explain the formation of the observed products (Scheme 26). ³⁵

Alternatively, the oxidative trifluoromethylation of unactivated olefins with the system CF₃SO₂Na/AgNO₃/K₂S₂O₈ at room temperature provided a straightforward access to α-trifluoromethyl ketones in good yields with O₂ as an ultimate oxygen source.³⁴ α-Trifluoromethylated ketones could also be obtained by reaction of styrenes and Umemoto’s reagent ⁷ in the presence of Na₂S₂O₄ or NaSO₂CH₂OH. Following the same principle as in the previous case, these reagents could reduce the sulphonium salt to generate a CF₃ radical which reacted with styrene so that after oxidation with air, trifluoromethylated ketones were generated in moderate yields (21–39%).³⁵

A novel metal-free trifluoromethylaminoxylation of alkenes was reported by Studer’s group using TEMPONa.⁵⁷ This reagent was formed from TEMPO and sodium, whereas CF₃ radicals could be released from Tognii reagent ⁸ as shown in Scheme 28.

A diastereoselective trifluoromethylation of internal alkenes was reported by Studer’s group using TEMPONa.⁵⁷ This reagent was formed from TEMPO and sodium, whereas CF₃ radicals could be released from Tognii reagent ⁸ as shown in Scheme 28. The diastereoselectivity of the process was excellent when cyclic alkenes were used as starting materials (Scheme 29). The products (42) could be reduced with Zn/AcOH delivering synthetically useful β-trifluoromethylated secondary alcohols.

### 3.2 Alkene trifluoromethylation and C–N bond formation

In contrast to the numerous studies dealing with the ox trifluoromethylation of alkenes, the concomitant formation of C–N and C–CF₃ bonds has been much less developed. Sodeoka and co-workers described one of the first examples of this type of transformations. Allyl amines react with CuI and Togni’s reagent ⁸ to give aziridines ⁴₃ in high yields by trifluoromethylation and intramolecular C–N bond formation (Scheme 30).⁵⁸ One pot reactions including the ring-opening of the aziridine in the presence of various nucleophiles set the path for the efficient synthesis of β-trifluoromethylamines, which are important building blocks for bioactive compounds.

An intermolecular aminotrifluoromethylation of terminal alkenes by photoredox catalysis was also described using [Ru(bpy)₃]²⁺ under
visible light irradiation with Umemoto’s reagent 7 as a precursor of CF₃ radicals leading to a-trifluoromethylamines 44 (Scheme 31). Good levels of stereoselectivity were obtained in the reactions of internal alkenes (Scheme 32).59

3.3 Alkene trifluoromethylation and C–S bond formation. β-Sulfanyl-(trifluoromethyl)-alkanes 47 could be obtained by photolysis of trifluoromethanethiosulfonates 45 or trifluorothioacetates 46. The trifluoromethyl radicals generated under UV radiation could then be trapped by the double bond, although yields remained moderate and products 48, resulting from a formal hydrotrifluoromethylation reaction, could also be detected in the reaction media. This process is highly regio-selective so that the product stemmed from the addition of the CF₃ radical on the less hindered carbon of the alkene (Scheme 33).60

3.4 Alkene trifluoromethylation and C–halogen bond formation. Formally, the one-pot trifluoromethylation and C–halogen bond formation across double bonds were first described in the 50’s when olefin polymerizations were carried out in the presence of iodotrifluoromethane.61 Thus, the reaction of iodotrifluoromethane with tetrafluoroethylene enabled the synthesis of short-chain tetrafluoroethylene polymers with general formula CF₃–[CF₂–CF₂]ₙ–I (ₙ = 1–10).

Decades later, the reaction of polyfluoroalkyl halides with alkenes and alkynes catalyzed by iron, cobalt and ruthenium complexes produced the corresponding addition products 49 in moderate to excellent yields (Scheme 34).62 Other metals such as platinum,63 nickel63 or palladium64,65 could also be used to catalyze this reaction.

Trifluoromethanesulphonyl chloride66 and perfluoroalkanesulphonyl chlorides67 could also be incorporated into alkenes in a reaction catalyzed by a ruthenium(II) complex as shown in Scheme 35.

Addition of CF₂Br₂, CF₃I and (CF₃)CFI to allylbenzenes could be carried out by sodium dithionite in a H₂O:MeCN mixture through a simple chain radical mechanism (Scheme 36).68 The reaction of CF₂Br₂ and CF₃I with allylbenzenes had to be performed in a closed system because of the volatility of the products.
iodides under visible-light irradiation produced trifluoromethylated alkenyl moieties, we have showcased the most synthetically useful trifluoromethylation of arynes, which accelerated the iodination and suppressed the undesired protonation yielding by-product whereas the addition of (CF₃)₂CFI was carried out in the presence of NaHCO₃ as a HI scavenger.

Recently, alkynes in the presence of [Ru(phen)₃]Cl₂ and TMEDA under visible-light irradiation produced trifluoromethylated alkynyl iodides in an E-selective manner. Trifluoromethylation and iodination of arynes were also described using AgCF₃ (generated in situ by mixing TMSCF₃ and AgF) in the presence of 2,2,6,6-tetramethylpiperidine, which accelerated the iodination and suppressed the undesired protonation yielding by-product 52 (Scheme 38).

Conclusions

As a result of the growing interest in the efficient synthesis of fluorinated molecules, alkenes have aroused as highly valuable building blocks for the construction of C–CF₃ bonds. In this review, we have aimed to show the latest progress in the incorporation of CF₃ groups across C=C π-systems: from the formal addition of HCF₃ to the simultaneous formation of C–CX and C–CF₃ bonds to produce X–C–C–CF₃ moieties, we have showcased the most synthetically useful methodologies and the corresponding mechanistic manifolds operating in this rapidly evolving field.
