Introduction

Recently, core–shell NPs have received considerable attention due to their remarkable properties. Combining two different materials (core and shell) changes the properties of the original core and the shell.¹ Among core-shell NPs, core-shell nanorattles or yolk–shell nanoparticles possess interesting morphological features. Core–shell nanorattles or yolk–shell nanostructures have advantages because of their core@void@ shell configuration. Core–shell nanorattles possess enhanced properties due to the void space between the core and the shell.^{1,2} Core-shell nanorattles based on metal oxides have several promising applications such as in drug delivery, catalysis, sensing, Li-ion batteries, and adsorption.^{2,3} Lee *et al.* have reported $Au@SiO₂$ yolk-shell structures as catalyst for the reduction of p-nitrophenol.⁴ Kandula *et al.* have reported peroxidase-like activity of $SiO_2@Co_3O_4$ nanorattles.⁵ Chen *et al.* have reported lithium storage properties of α -Fe₂O₃@SnO₂ nanorattles.⁶ Rokicinska et al. have reported $Co_3O_4@SiO_2$

Synthesis of $SiO₂QMnCo₂O₄ core-shell$ nanorattles using layered double hydroxide precursors and studies on their peroxidase-like activity†

Pankai Rana \blacksquare and Pethaiyan Jeevanandam \blacksquare^*

The current work demonstrates a simple soft chemical approach to synthesize $SiO₂@MnCo₂O₄ core$ shell nanorattles using SiO₂@MnCo-LDH (layered double hydroxide) precursors. XRD analysis indicates the formation of $MnCo₂O₄$ nanoparticles (NPs) on SiO₂ spheres. FESEM images show hierarchical flower-like MnCo₂O₄ NPs on the surface of the SiO₂ spheres. TEM micrographs show the interstitial space between the core (SiO₂) and the shell (MnCo₂O₄), indicating the core–shell nanorattle morphology of SiO₂@MnCo₂O₄. BET adsorption–desorption isotherms of the SiO₂@MnCo₂O₄ core–shell nanorattles indicate their mesoporous nature with high surface area. Optical studies indicate $O^{2-} \to Mn^{2+}$ and $O^{2-} \rightarrow Co^{3+}$ charge-transfer transitions and d-d transition in pure MnCo₂O₄ NPs and the SiO₂@Mn- $Co₂O₄$ core–shell nanorattles. XPS measurements indicate the presence of Si⁴⁺, Mn²⁺, Co²⁺, Mn³⁺, $Co³⁺$, and $O²⁻$ in the SiO₂@MnCo₂O₄ core–shell nanorattles. The SiO₂@MnCo₂O₄ core–shell nanorattles show paramagnetic and superparamagnetic behavior at 300 K and 5 K, respectively. After characterization, the $SiO_2@MnCo_2O_4$ core–shell nanorattles were explored for peroxidase-like activity for the first time. The SiO₂@MnCo₂O₄ core–shell nanorattles act as a peroxidase nanozyme and exhibit better peroxidase-like activity than pure $MnCo₂O₄$ NPs and horseradish peroxidase. **PAPER**

been used in different applications. For example, Wang et al. have reported MnCo₂O₄@MnCo₂S₄ core-shell nanostructures for asymmetric supercapacitors.¹⁹ Zhao et al. have reported $MnCo₂O₄(@Ni(OH)₂ core-shell flowers with ultrahigh specific$ capacitance.²⁰ Li et al. have reported MnCo₂O₄@NiCo₂O₄ core– shell NPs for dye-sensitized solar cells.²¹ Sun et al. have reported MnCo₂O₄@C core–shell nanowires for water splitting.²² Zhao et al. have reported Co_3O_4 @Mn Co_2O_4 core–shell nanowire arrays for electrochemical energy storage.²³ Mehrez *et al.* have reported $MnCo₂O₄(Q)$ Ni $MoO₄$ core–shell nanowire arrays for supercapacitor applications.²⁴

Enzymes are biocatalysts that catalyze several biochemical reactions with high efficiency and selectivity.²⁵ Natural enzymes have several limitations. They have low stability, complex storage requirements, high cost, and less adaptability under harsh environmental conditions.²⁶ To overcome the drawbacks of natural enzymes, nanomaterials have been used as an alternative. Metal oxide-based nanozymes have been explored to mimic different natural enzymes such as peroxidase, ferroxidase, catalase, and superoxide dismutase.^{26,27} Horseradish peroxidase oxidizes different substrates in the presence of hydrogen peroxide.²⁸ In the literature, different metal oxide-based nanozymes have been used as a peroxidase mimic. For example, Chen et al. have reported CuO nanoparticles for peroxidase-like activity.²⁹ Fu et al. have investigated the peroxidase-like activity of $Fe₃O₄$ nanoparticles for cancer therapy.³⁰ Gao *et al.* have reported $MnCo₂O₄$ nanofibers as a catalyst for peroxidase-like activity.³¹ Ma et al. have reported photoinduced peroxidase-like activity of NiCo₂O₄@MnO₂ nanozymes.³² **Paper**

Multi-functional core–shell NPs and nanorattles have been synthesized using various soft chemical synthesis routes. For example, Wang et al. have reported the synthesis of $MnCo₂O₄(@MnCo₂S₄)$ core–shell nanostructures using the hydrothermal method.¹⁹ Zhao et al. have reported the synthesis of $MnCo₂O₄(@Ni(OH)₂ core-shell)$ flowers using homogeneous precipitation.²⁰ Mehrez et al. have reported the synthesis of MnCo₂O₄@NiMoO₄ core-shell nanowires using hydrothermal method.²⁴ Zhang et al. have reported the preparation of Co@CoO core–shell nanocomposites using solvothermal method. 33 Gao et al. have reported the synthesis of NiCo2O4@SnO2 hetero-nanostructures using the hydrothermal method.³⁴ Kandula *et al.* have reported the preparation of $SiO₂(a)$ NiCo₂O₄ core-shell nanorattles using homogeneous precipitation.³⁵

The current work demonstrates a reliable and cost-effective synthetic strategy to prepare $SiO_2@MnCo_2O_4$ nanorattles via calcination of $SiO_2@MnCo-LDH$ precursors at 500 °C. The $MnCo₂O₄$ nanoparticles deposit on the surface of the $SiO₂$ spheres creating a hollow space (void) between the core and shell. The influence of $[Mn^{2+}$: Co²⁺] ratio on the thickness of the $MnCo₂O₄$ shell and void distance between the core (SiO₂) and shell (MnCo₂O₄) has been investigated. The SiO₂@MnCo₂O₄ core–shell nanorattles exhibit better peroxidase-like activity than pure $MnCo₂O₄$ NPs using 3,3',5,5'-tetramethylbenzidine (TMB) as the substrate. To the best of the authors' knowledge, there is no report on the synthesis of $SiO_2@MnCo_2O_4$ core-shell nanorattles and the $SiO_2@MnCo_2O_4$ nanorattles have been employed as a peroxidase mimic for the first time.

Experimental

Reagents

Tetraethyl orthosilicate (98%, Sigma-Aldrich), ammonia solution (25%, Rankem), Mn($NO₃$)₂.4H₂O (97%, Sigma-Aldrich), Co($NO₃$)₂.6H₂O (98%, Merck), urea (99.5%, Rankem), 3,3',5,5'-tetramethylbenzidine (98%, Spectrochem Chemicals), ethanol (99.9%, Changshu Hongsheng Fine Chemical Co., Ltd.), and H_2O_2 (30%, Rankem, AR). All the chemicals were used as received.

Synthesis of silica microspheres

 $SiO₂$ microspheres were synthesized using a previously reported StÖber's method.³⁶ About 3.7 mL of tetraethyl orthosilicate was added (dropwise) to a mixture of 88 mL of EtOH and 12 mL of NH4OH solution with constant stirring. The reaction mixture was continuously stirred at RT for 24 h to get a white-colored product. The product was centrifuged, washed with EtOH, and dried in an oven overnight at 70° C.

Synthesis of $SiO_2@MnCo_2O_4$ core-shell nanorattles

First, $SiO₂@MnCo-LDH$ precursors were prepared using different molar ratios of $[Mn^{2+} : Co^{2+}]$. The synthetic parameters for the $SiO₂MnCo-LDH$ precursors are given in Table 1. In a typical synthetic experiment, $Mn(NO₃)₂·4H₂O$, $Co(NO₃)₂·6H₂O$ and urea were dissolved in 100 mL of distilled water in a 250 mL beaker. Then, $SiO₂$ microspheres (100 mg) were dispersed in the aqueous solution and sonicated for 10 minutes. The contents were heated at 85 °C for six hours with constant stirring. The product was collected by centrifuging and washing with deionized water and ethanol, followed by drying in an oven at 60 °C for about 12 h. The as-prepared $SiO₂@MnCo-LDH$ precursors were calcined at 500 $^{\circ}$ C (in a muffle furnace) for 3 h (heating rate $= 2 \degree C$ per minute) in air to get the corresponding SiO_2 @MnCo₂O₄ samples. The as-prepared SiO_2 @MnCo-LDH precursors, prepared using different molar ratios of $[Mn^{2+} : Co^{2+}]$ $(0.25:0.5, 0.5:1, and 1:2)$, will henceforth be referred to as $SiO₂(@MnCo-LDH-0.25, SiO₂(@MnCo-LDH-0.5, and SiO₂(@MnCo-LOH-0.25, and SiO$ LDH-1, respectively. The $SiO_2@MnCo_2O_4$ samples, obtained on calcination, will henceforth be referred to as $SiO_2@MnCo_2O_4-0.25$, SiO_2 @MnCo₂O₄-0.5, and SiO_2 @MnCo₂O₄-1, respectively.

Peroxidase-like activity and kinetic analysis

The peroxidase-like activity of the $SiO_2@MnCo_2O_4$ nanorattles was studied utilizing tetramethylbenzidine (TMB) and H_2O_2 as a substrate, and oxidizing agent, respectively. About 300 µL of 3 mM TMB solution (DMSO) and 31 μ L of 100 mM H_2O_2 were mixed with 3 mL of acetate buffer (0.1 M, pH = 5). Then, 30 μ L

Table 1 Synthetic details of SiO₂@MnCo-LDH samples and their nomenclature

of catalyst dispersion (1 mg of SiO_2 @MnCo₂O₄ catalyst dispersed by sonication in 1 mL of deionized water) was added to the reaction mixture. The absorbance values (ω_{max} = 652 nm) of the reaction mixture were measured using a UV-Vis spectrophotometer (Shimadzu UV-2600) up to 10 minutes. Kinetic experiments were performed by changing various experimental parameters, such as TMB concentration (0.05 to 0.5 mM), pH (2– 12), catalyst dose (5–60 μ L), and H₂O₂ concentration (5–200 mM). The kinetic parameters $(K_m$ and $V_{max})$ were estimated using the Michaelis–Menten equation and Lineweaver–Burk reciprocal plots.32 The Michaelis–Menten equation is as follows.

$$
1/V = (K_{\rm m}/V_{\rm max}) (1/[S]) + 1/V_{\rm max}
$$

where K_m and V_{max} denote the Michaelis–Menten constant and maximum reaction velocity, respectively. V and [S] denote reaction velocity and concentration of the substrate (TMB), respectively.

Terephthalic acid was employed as a probe molecule to prove the role of hydroxyl radicals in the peroxidase-like activity of the $SiO_2@MnCo_2O_4$ nanorattles. In a cuvette, buffer (3 mL, $pH = 5$) and 100 mM $H₂O₂$ (31 µL) were mixed, followed by the addition of 30 μ L of catalyst dispersion (SiO₂@MnCo₂O₄). The reaction mixture was then treated with 0.5 mL of aqueous terephthalic acid solution (0.5 mM). A spectrofluorometer (Horiba Scientific, Fluoromax-4) was used to measure the PL spectra of the solution (λ_{exc} = 315 nm) up to 50 minutes.

Characterization

Powder X-ray diffraction patterns of all the samples were recorded using a Bruker AXS D8 Advance powder X-ray diffractometer (Cu-K_{α}) $(\lambda = 1.5406 \text{ Å})$, scan speed = 1° min⁻¹) in the 2 θ range of 5° to 90°. FT-IR spectra of the samples (using KBr pellets) were recorded using a Thermo Nicolet Nexus FT-IR spectrophotometer (4000 to 400 cm-1). A PerkinElmer Pyris Diamond instrument was used to perform thermal gravimetric analysis (TGA) of the $SiO₂(\text{a})$ MnCo-LDH precursors; the precursors were heated at a rate of 10 $^{\circ}\mathrm{C}\min^{-1}$ in air between 30 \degree C and 1000 \degree C. A Carl Zeiss Gemini scanning electron microscope (operating voltage = 20 kV) was used to examine the morphology of the samples. For elemental analysis, the SEM attached with an EDXA unit was employed. The core–shell nanorattles were imaged using an FEI Tecnai G2 20S-TWIN transmission electron microscope (operating voltage = 200 kV). Using a Quantum Design MPMS3 superconducting quantum interference device, the magnetic properties of the $SiO₂(\mathfrak{D}MnCo₂O₄)$ core–shell nanorattles were studied. X-ray photoelectron spectroscopy (XPS) measurements were performed on a Physical Electronics make (PHI 5000 Versa Probe III) spectrometer (Al-K_{α} radiation, energy = 1486.6 eV). Physisorption of N_2 at 77 K was used to determine surface area of the $SiO₂(@MnCo₂O₄ core-shell nanorattles using a Quantachrome$ BET surface area analyzer (model = Nova 2200e).

Results and discussion

The results related to $SiO₂(@MnCo-LDH$ precursors are given in the ESI.[†] The results related to $SiO_2@MnCo_2O_4$ core–shell nanorattles are discussed below.

SiO₂@MnCo₂O₄ core-shell nanorattles

Phase analysis. Pure $MnCo₂O₄$ NPs and $SiO₂(@MnCo₂O₄)$ core–shell NPs were obtained on calcination of MnCo-LDH and $SiO₂(\mathfrak{D}MnCo-LDH)$ samples at 500 °C, respectively. The XRD patterns of the $MnCo₂O₄$ and $SiO₂(@MnCo₂O₄$ samples are shown in Fig. 1. The XRD pattern of $MnCo₂O₄$ matches with the pattern of cubic $MnCo₂O₄$ (JCPDS file no. 23-1237). The peaks observed at $2\theta = 18.1^{\circ}$, 30.4° , 35.9° , 43.9° , 53.5° , 58.4° , and 64.5 $^{\circ}$ are ascribed to (111), (220), (311), (400), (422), (511), and (440) reflections of cubic $MnCo₂O₄$. The XRD patterns of the $SiO_2@MnCo_2O_4-0.25$ and $SiO_2@MnCo_2O_4-0.5$ samples show peaks at $2\theta = 35.9^{\circ}$ and 64.5° attributed to the (311) and (440) planes of MnCo₂O₄. NJC

the reaction

The XRD pattern of $SiO_2@MnCo_2O_4$ -1 shows peaks at 2θ = 18.1°, 30.2°, 35.9°, 43.7°, 58.3°, and 64.3° due to (111), (220), (311) , (400) , (511) , and (440) reflections of MnCo₂O₄. The estimated crystallite size (using the Scherrer formula) of $MnCo₂O₄$ are 9.3 nm, 6.4 nm, 3.5 nm, and 7.5 nm for $MnCo₂O₄$, SiO_2 @MnCo₂O₄-0.25, SiO₂@MnCo₂O₄-0.5, and SiO₂@Mn- $Co₂O₄$ -1, respectively. The $SiO₂(@MnCo₂O₄$ samples possess smaller crystallites of $MnCo₂O₄$ compared to pristine $MnCo₂O₄$ NPs.

FT-IR analysis

Fig. S5 (ESI†) displays the FT-IR spectra of $MnCo₂O₄$ and $SiO_2@MnCo_2O_4$ samples $(SiO_2@MnCo_2O_4-0.25, SiO_2@Mn Co₂O₄$ -0.5, and $SiO₂(@MnCo₂O₄-1)$. The IR spectra of all the samples exhibit bands at about 3438 cm^{-1} , and 1637 cm^{-1} assigned to stretching and bending vibrational modes of physisorbed H_2O molecules. The IR spectrum of $MnCo_2O_4$ shows IR bands around 659 cm^{-1} and 568 cm^{-1} attributed to stretching vibration of Co–O and Mn–O bonds, respectively.¹⁴ The IR spectra of all the $SiO_2@MnCo_2O_4$ samples display characteristic bands of SiO $_2$ at 1105 $\rm cm^{-1}$ and 486 $\rm cm^{-1}$ due to v -(Si–O–Si) and δ -(Si–O–Si), respectively.⁵ In the IR spectra of the SiO₂@Mn- $Co₂O₄$ samples, the bands observed at about 660 cm⁻¹ and 565 cm^{-1} are assigned to the stretching vibrations of Co-O and Mn–O bonds, respectively.¹⁴

Fig. 1 XRD patterns of $MnCo₂O₄$ and $SiO₂@MnCo₂O₄$ samples obtained by calcination of LDH precursors (Table 1) at 500 °C.

Paper NJC

Morphological studies and elemental analysis

Fig. 2(a–d) displays FESEM images of pure $MnCo₂O₄$ and SiO_2 @MnCo₂O₄ samples (SiO₂@MnCo₂O₄-0.25, SiO₂@Mn- $Co₂O₄$ -0.5, and $SiO₂(@MnCo₂O₄-1)$. The FESEM image of pure $MnCo₂O₄$, (Fig. 2(a)) shows nanosheets (flake-like structures). The FESEM images of the $SiO_2@MnCo_2O_4$ samples (Fig. 2(b-d)) show that the $SiO₂$ spheres are uniformly covered with $MnCo₂O₄$ nanoparticles. Table S4 (ESI†) summarizes the EDX analysis results for all $SiO_2@MnCo_2O_4$ samples (after calcination at 500 $^{\circ}$ C). The results indicate that Si, Mn, Co, and O are present uniformly in all the $SiO_2@MnCo_2O_4$ core–shell NPs. The weight % of Mn and Co in the $SiO_2@MnCo_2O_4$ samples varies according to the $[Mn^{2+}]:[Co^{2+}]$ ratio used during the synthesis of their precursors $(SiO₂@MnCo-LDH)$.

Fig. 3(a–e) shows the TEM images of $SiO₂$, pristine MnCo₂O₄, and $SiO_2@MnCo_2O_4$ samples $(SiO_2@MnCo_2O_4-0.25, SiO_2@Mn Co₂O₄$ -0.5, and $SiO₂(\mathfrak{D}MnCo₂O₄-1)$. A summary of the TEM results is given in Table 2. The TEM image of $SiO₂$ (Fig. 3(a)) shows spherical particles with mean diameter of 175 ± 14 nm. Fig. 3(b) displays the TEM image of pristine $MnCo₂O₄$, showing its flakelike morphology (nanosheet). The mean thickness of $MnCo₂O₄$ nanosheets is 9.3 ± 3.6 nm. The TEM images (Fig. 3(c–e)) of $SiO_2@MnCo_2O_4$ samples $(SiO_2@MnCo_2O_4-0.25, SiO_2@MnCo_2O_4-0.25)$ 0.5, and $SiO_2@MnCo_2O_4-1$) show interstitial space (void) between the core $(SiO₂)$ and the shell $(MnCo₂O₄)$. Such nanoparticles are known in the literature as core–shell nanorattles or nanoparticles with yolk-shell morphology.^{37,38} The TEM images also reveal that the $MnCo₂O₄$ shell has a porous flower-like structure. From Table 2, it is observed that the mean size of the $SiO₂$ core in the SiO₂@MnCo₂O₄ core–shell nanorattles varies from 171 \pm 13 nm to 190 ± 15 nm. The mean thickness of the MnCo₂O₄ shell lies in the range of 38 \pm 8 nm to 60 \pm 12 nm. The average void distance between the SiO₂ core and MnCo₂O₄ shell varies from 16 \pm 3 nm to 30 \pm 6 nm. The mean thickness of the nanosheets of MnCo₂O₄ (shell) in the SiO_2 @MnCo₂O₄ core–shell nanorattles varies from 2.6 ± 0.9 nm to 3.3 ± 0.4 nm. The synthetic conditions play an

Fig. 3 TEM images of (a) $SiO₂$, (b) $MnCo₂O₄$, (c) $SiO₂@MnCo₂O₄ - 0.25$, (d) SiO₂@MnCo₂O₄-0.5 and (e) SiO₂@MnCo₂O₄-1 core–shell samples calcined at 500 °C.

Table 2 Summary of TEM results of $SiO_2@MnCo_2O_4$ core–shell nanorattles

Sample code	Core size (nm) (nm)	Shell	Void	thickness distance Flake thickness (nm) in the shell (nm)
SiO_2 (a) MnCo ₂ O ₄ -0.25 182 \pm 13 38 \pm 8 SiO_2 (a) MnCo ₂ O ₄ -0.5 171 \pm 13 41 \pm 10 $SiO_2@MnCo_2O_4$ -1 190 ± 15 60 ± 12			$22 + 4$	30 ± 6 2.6 ± 0.9 $16 + 3$ $3.2 + 0.6$ $3.3 + 0.4$

important role in the nanorattle formation. As the concentration (molar ratio) of metal salts used during the synthesis of SiO₂@MnCo-LDH precursors (*i.e.* Mn(NO₃)₂·4H₂O and Co(NO₃)₂· $6H₂O$) increases from 0.25:0.5 to 1:2, more $MnCo₂O₄$ NPs are formed on the surface of the $SiO₂$ spheres, which leads to a thick coating of $MnCo₂O₄$ NPs on the surface of the $SiO₂$ spheres. When lower concentration of metal salts is used, a thin coating of $MnCo₂O₄$ NPs occurs and thus in the $SiO₂(\partial MnCo₂O₄-0.25$ sample, the thin coating of $MnCo₂O₄$ leads to a good TEM image. EDS mapping and elemental line profiles of $SiO₂(\mathfrak{D}MnCo₂O₄$ from TEM measurements were done and the results are shown in Fig. S6 and S7 (ESI†). The EDS elemental mapping images and elemental line profile of the $SiO_2@MnCo_2O_4$ core–shell nanorattles indicate

uniform distribution of elements (Si, Mn, Co and O) in the $SiO₂@MnCo₂O₄$ core–shell nanorattles. The line scan EDS images show that the Mn and Co content is more towards the edge of the spherical particles and the Si content is more in the center of the particles. This suggests coating of $MnCo₂O₄$ on the $SiO₂$ spheres.

The SAED patterns of pure $MnCo₂O₄$ NPs and SiO₂@ $MnCo₂O₄$ samples $(SiO₂@MnCo₂O₄-0.25, SiO₂@MnCo₂O₄-0.5,$ and $SiO_2@MnCo_2O_4-1$ are displayed in Fig. $S8(a-d)$ (ESI[†]). The SAED pattern of pure $MnCo₂O₄$ (Fig. S8(a), ESI[†]) shows rings which indicate the polycrystalline nature of the $MnCo₂O₄$ NPs. The observed rings are attributed to (220), (311), (400), (422), and (440) reflections of cubic $MnCo₂O₄$. The SAED patterns of SiO_2 @MnCo₂O₄-0.25, SiO_2 @MnCo₂O₄-0.5, and SiO_2 @Mn- $Co₂O₄$ -1 core–shell nanorattles (Fig. S8(b–d), ESI†) also show rings, which suggests the polycrystalline nature of all the $SiO₂(\mathfrak{D}MnCo₂O₄)$ nanorattles. The observed rings correspond to the (311) and (422) planes of cubic $MnCo₂O₄$.

BET surface area analysis

BET surface area measurements were carried out to determine the surface area, pore size, and pore volume of the $SiO_2@Mn$ - $Co₂O₄$ core–shell nanorattles. $SiO₂$ and $MnCo₂O₄$ nanoparticles exhibit a surface area of 88 $\mathrm{m^2\,g^{-1}}$ and 79 $\mathrm{m^2\,g^{-1}}$, respectively. The core–shell nanorattles $(SiO₂@MnCo₂O₄-0.25, SiO₂@Mn Co₂O₄$ -0.5, and $SiO₂(\mathfrak{D}MnCo₂O₄-1)$ exhibit surface area of 278 $\mathrm{m^2\ g^{-1}}$, 302 $\mathrm{m^2\ g^{-1}}$, and 356 $\mathrm{m^2\ g^{-1}}$, respectively. The higher surface area of the SiO_2 @MnCo₂O₄ nanorattles is attributed to the void space between the core $(SiO₂)$ and the shell ($MnCo₂O₄$). Adsorption–desorption isotherms were recorded for pure $MnCo₂O₄$ nanoparticles and $SiO₂(\partial MnCo₂O₄-1$. As shown in Fig. S9(a) (ESI†), the adsorption-desorption isotherm of the $MnCo₂O₄$ nanoparticles shows the characteristics of a porous material with open wedge pores. The adsorption– desorption isotherm of $SiO_2@MnCo_2O_4$ -1 (Fig. S9(b), ESI[†]) matches with a type IV isotherm.³⁹ The $MnCo₂O₄$ nanoparticles exhibit an average pore size and pore volume of 6.2 nm and 0.12 cm³ g⁻¹, respectively. The SiO₂@MnCo₂O₄-1 exhibits an average pore size and pore volume of 5.0 nm and 0.44 $\rm cm^3~g^{-1},$ respectively.

Mechanism of formation of SiO_2 @MnCo₂O₄ core-shell nanorattles

Fig. S10 (ESI†) shows the proposed mechanism of formation of $SiO_2@MnCo_2O_4$ core–shell nanorattles. In the first step, Mn^{2+} and $Co²⁺$ ions from the aqueous solution attach to the OH groups present on the surface of the $SiO₂$ spheres via electrostatic interaction. At 85 $^{\circ}$ C, hydrolysis of urea leads to the production of NH_4^+ and OH^- ions. The OH^- ions react with Mn^{2+} and Co^{2+} ions present on the surface of SiO₂ forming MnCo-LDH via nucleation and coalescence processes. Finally, flower-like structures consisting of MnCo-LDH nanosheets are formed on the surface of the $SiO₂$ spheres via Ostwald ripening.^{40,41} The flower-like SiO_2 @MnCo-LDH precursors are converted into $SiO_2@MnCo_2O_4$ core-shell nanorattles via calcination at 500 \degree C with retention of the morphology.

Time-dependent TEM studies were carried out to understand better the formation of $SiO_2@MnCo-LDH$ nanorattles. The TEM images of $SiO_2@MnCo-LDH-0.25$ recorded after different reaction times (1 h, 2 h, 3 h, 4 h, and 6 h) are shown in Fig. S11 (ESI†). After a reaction time of 1 h, MnCo-LDH crystallites are loosely attached on the outer surface of the $SiO₂$ spheres. These MnCo-LDH crystallites act as seed for the nucleation and recrystallization. As the reaction progresses (2 h, 4 h), Ostwald ripening (inside-out) dominates and smaller crystallites of MnCo-LDH present in the interior region dissolve, which initiates the hollowing process. Finally, after 6 h, a close-packed MnCo-LDH shell is formed on the surface of the $SiO₂$ spheres with a void space between the core and shell. $SiO₂(\mathfrak{D}MnCo₂O₄$ core–shell nanorattles are obtained on calcination of SiO_2 @MnCo-LDH at 500 °C with the retention of the morphological features of the LDH precursor. Optical properties of $SiO_2@MnCo_2O_4$ core–shell nanorattles

The optical properties of $MnCo₂O₄$ nanoparticles and $SiO₂@MnCo₂O₄$ core–shell nanorattles were studied using UV-Vis diffuse reflectance spectroscopy (DRS). The UV-Vis DRS spectra of the MnCo₂O₄ nanoparticles and SiO₂@MnCo₂O₄ core–shell nanorattles are shown in Fig. S12 (ESI†). The DRS spectra of the MnCo₂O₄ NPs and SiO₂@MnCo₂O₄ nanorattles show broad bands at 250 nm and 470 nm, attributed to $O^{2-} \rightarrow$ Mn²⁺ and $O^{2-} \rightarrow$ Co³⁺ charge-transfer transitions of MnCo₂O₄, respectively.^{43,44} The DRS spectra of all the samples exhibit a broad band at about 738 nm due to d-d transitions of Mn^{2+} and Co^{3+} of MnCo₂O₄ NPs.^{42,43}

XPS analysis

The oxidation states of Si, Mn, Co, and O in SiO_2 , MnCo₂O₄ NPs and $SiO_2@MnCo_2O_4$ -1 nanorattles were determined using XPS analysis.

Fig. S13 (ESI†) displays the XPS spectrum of $SiO₂$. The Si 2p spectrum of $SiO₂$ shows a peak at 103.8 eV, indicating the existence of Si^{4+} . The O 1s spectrum of SiO_2 shows peaks at 532.7 eV and 533.8 eV, indicating the existence of lattice oxygen and surface hydroxyl oxygen in SiO_2 , respectively.⁴⁴ Fig. 4(a and b) shows the XPS spectra of pure $MnCo₂O₄$ NPs and SiO₂@Mn- $Co₂O₄$ -1. The Mn 2p spectrum of pure MnCo₂O₄ NPs (Fig. 4(a)) shows peaks due to Mn $2p_{3/2}$ (642.1 eV (Mn²⁺) and 643.5 eV (Mn^{3+}) and Mn 2p_{1/2} (654.0 eV). The Co 2p spectrum of $MnCo₂O₄$ NPs (Fig. 4(a)) shows peaks due to Co $2p_{3/2}$ (780.1 eV (Co²⁺) and 782.1 eV (Co³⁺) and Co 2p_{1/2} (795.2 eV (Co^{2+}) and 797.3 eV (Co^{3+})). The peaks observed at 788.0 eV and 803.8 eV correspond to satellite peaks. The O 1s spectrum of pure $MnCo₂O₄$ NPs shows peaks at 530.1 eV and 531.9 eV, assigned to lattice oxygen of $MnCo₂O₄$ and surface hydroxyl oxygen, respectively.^{45,46} The Si 2p XPS spectrum of SiO_2 @ $MnCo₂O₄$ -1 (Fig. 4(b)) shows a peak at 102.7 eV, suggesting the presence of Si^{4+} . The Mn 2p spectrum of $SiO_2@MnCo_2O_4-1$ (Fig. 4b) exhibits peaks due to Mn $2p_{3/2}$ (642.2 eV (Mn²⁺) and 644 eV (Mn^{3+}) and Mn 2p_{1/2} (654.2 eV (Mn^{3+})). The Co 2p spectrum of $SiO_2@MnCo_2O_4$ -1 (Fig. 4b) shows peaks due to Co $2p_{3/2}$ (781.1 eV (Co²⁺) and 782.7 eV (Co³⁺)) and Co $2p_{1/2}$

Fig. 4 XPS spectra of (a) $MnCo₂O₄$ NPs and (b) SiO₂@MnCo₂O₄-1 core– shell nanoparticles calcined at 500 °C.

(796.8 eV (Co^{2+}) and 797.8 eV (Co^{3+})). Two satellite peaks are also observed at 787.5 eV and 803.5 eV. The O 1s spectrum of $SiO₂(\mathfrak{D}MnCo₂O₄-1$ (Fig. 4b) exhibits peaks at 530.2 eV and 531.4 eV due to lattice oxygen of $MnCo₂O₄$ and surface hydroxyl oxygen, respectively.44–46

Magnetic properties

Magnetic hysteresis $(M-H)$ plots of pure MnCo₂O₄ NPs and $SiO₂(\mathfrak{D}MnCo₂O₄)$ nanorattles were recorded at RT (300 K) and 5 K up to an applied field of 40 kOe. The M–H curves of pure $MnCo₂O₄$ NPs and $SiO₂(@MnCo₂O₄$ samples $(SiO₂(@MnCo₂O₄ -$ 0.25, $SiO₂(@MnCo₂O₄-0.5, and SiO₂(@MnCo₂O₄-1)$ are shown in Fig. 5. At 300 K, the absence of hysteresis and negligible coercivity indicate paramagnetic nature of the pure $MnCo₂O₄$ NPs and all the $SiO_2@MnCo_2O_4$ samples. Table 3 gives the coercivity and magnetization values of pure $MnCo₂O₄$ NPs and $SiO₂(\mathfrak{D}MnCo₂O₄$ samples at 5 K. At 5 K, the *M-H* hysteresis loop

of the $MnCo₂O₄$ nanoparticles exhibits coercivity of 5.0 kOe and magnetization of 6.8 emu g^{-1} (@40 kOe), indicating hard ferromagnetic behavior. At 5 K, the negligible coercivity and finite magnetization of all the $SiO_2@MnCo_2O_4$ samples indicate superparamagnetic behavior. The coercivity values for SiO_2 @MnCo₂O₄-0.25, SiO₂@MnCo₂O₄-0.5, and SiO₂@MnCo₂O₄-1 at 5 K are 0.05 kOe, 0.02 kOe, and 0.09 kOe, respectively. For SiO_2 @MnCo₂O₄-0.25, SiO₂@MnCo₂O₄-0.5, and SiO₂@MnCo₂O₄-1, the magnetization values (@40 kOe) at 5 K are 46.5 emu g^{-1} , 36.3 emu g^{-1} , and 25.5 emu g^{-1} , respectively.

At low temperature, the dominance of magneto-crystalline anisotropy leads to higher coercivity and magnetization of the $MnCo₂O₄$ nanoparticles and $SiO₂(\partial MnCo₂O₄$ samples.⁴⁷ The lower coercivity of SiO_2 @MnCo₂O₄ nanorattles compared to pure $MnCo₂O₄$ nanoparticles is attributed to the diamagnetic $SiO₂$ phase in the nanorattles.⁴⁸ The higher magnetization of SiO_2 @MnCo₂O₄ samples compared to pure MnCo₂O₄ NPs is attributed to smaller crystallite size of $MnCo₂O₄$ NPs in the SiO_2 @MnCo₂O₄ samples. In the MnCo₂O₄ nanoparticles, $SiO_2@MnCo_2O_4-0.25$, $SiO_2@MnCo_2O_4-0.5$, and $SiO_2@$ $MnCo₂O₄$ -1, the crystallite size of $MnCo₂O₄$ are 9.3 nm, 6.4 nm, 3.5 nm, and 7.5 nm, respectively. The ZFC and FC magnetization curves recorded under 2 kOe for pure $MnCo₂O₄$ NPs and $SiO_2@MnCo_2O_4$ nanorattles $(SiO_2@MnCo_2O_4-0.25,$ $SiO_2@MnCo_2O_4-0.5$, and $SiO_2@MnCo_2O_4-1$ are shown in Fig. 6. The ZFC and FC curves of pure $MnCo₂O₄$ NPs display a bifurcation at about 100 K and a hump at 25 K, which are assigned as irreversible temperature (T_{irr}) and blocking temperature (T_{B}) , respectively. All the SiO₂@MnCo₂O₄ core-shell nanorattles show overlapped ZFC and FC curves without any hump, indicating superparamagnetic nature of the samples despite the absence of a maximum in the ZFC curve. The absence of maxima in the ZFC curves of the $SiO_2@MnCo_2O_4$ samples is due to the absence of ferrimagnetic ordering in these samples. $49-52$

Peroxidase-like activity of $SiO_2@MnCo_2O_4$ nanorattles

The current study demonstrates the peroxidase-like activity of pure $MnCo₂O₄$ nanoparticles and $SiO₂(@MnCo₂O₄$ core–shell nanorattles (SiO₂@MnCo₂O₄-0.25, SiO₂@MnCo₂O₄-0.5, and SiO₂@Mn- $Co₂O₄$ -1). The SiO₂@MnCo₂O₄ core–shell nanorattles were tested as catalyst for peroxidase-like activity using TMB and H_2O_2 as substrate and oxidizing agent, respectively. The oxidation of TMB using $SiO_2@MnCo_2O_4$ core–shell nanorattles in the presence of $H₂O₂$ leads to formation of TMB^{*+} (blue-colored charge transfer complex). The UV-Vis spectrum of TMB^{*+} consists of a characteristic absorption maximum at 652 nm.²⁸ An intense blue-colored solution is obtained using $SiO_2@MnCo_2O_4$ as the catalyst compared to pure $MnCo₂O₄$ NPs, which suggests the role of $SiO₂(a)$ $MnCo₂O₄$ as the catalyst in peroxidase-like activity.

The UV-Vis spectral results (abs. vs. time plots) and % relative efficiency of peroxidase-like activity for pure $MnCo₂O₄$ NPs and $SiO₂(\mathfrak{D}MnCo₂O₄$ core–shell NPs are shown in Fig. 7 and Fig. S14 (ESI†), respectively. As shown in Fig. 7, compared to pure $MnCo₂O₄$ nanoparticles, $SiO₂(\partial MnCo₂O₄$ nanorattles show better peroxidase-like activity. $SiO_2@MnCo_2O_4$ -1 exhibits the best peroxidase-like activity among the $SiO_2@MnCo_2O_4$ samples.

Influence of physicochemical conditions on the peroxidase-like activity

In the current study, various experimental parameters were varied to achieve optimal conditions for the peroxidase-like

activity of the $SiO_2@MnCo_2O_4$ core–shell nanorattles. Studies were carried out to investigate the effect of varying $pH (2-12)$ and amount of catalyst $(5 \mu L - 60 \mu L)$ of dispersion) on the peroxidase-like activity of the $SiO_2@MnCo_2O_4$ core–shell nanorattles. The influence of varying pH (2–12) on the peroxidase-like activity (Fig. S15(a), ESI†) reveals the maximum peroxidase-like activity of $SiO_2@MnCo_2O_4$ core–shell nanorattles at pH = 5. At low pH (< 5) , protonation of amino groups of TMB occurs. The protonation of amino groups leads to the retardation of electron transfer from the substrate (TMB) to the catalyst surface $(SiO₂(\mathfrak{D}MnCo₂O₄-1)$. Hence, in a strongly acidic medium, the peroxidase-like activity of $SiO_2@MnCo_2O_4$ -1 decreases. When $pH > 5$, production of O₂ and H₂O occurs via the break-down of $H₂O₂$ in the presence of more hydroxyl ions, which leads to suppression of the peroxidase-like activity of $SiO_2@MnCo_2O_4$ -1.53,54 A linear variation of the peroxidase-like activity of $SiO₂@MnCo₂O₄$ -1 with an increment in catalyst dose from $5 \mu L$ to $60 \mu L$ of dispersion (1 mg catalyst dispersed by sonication in 1 mL H_2O) is observed (Fig. S15(b), ESI†). A leaching experiment was carried out to understand further the peroxidase-like activity of SiO_2 @MnCo₂O₄-1. In a typical experiment, $SiO_2@MnCo_2O_4$ -1 (30 µL dispersion) was incubated in 3 mL buffer ($pH = 5$) for about 30 minutes. The supernatant solution obtained by centrifugation was further examined for peroxidase-like activity by adding TMB and H_2O_2 solutions. The UV-Vis spectrum of the leached solution was recorded in kinetic mode up to 10 minutes (Fig. S16, ESI†). The negligible absorbance shown by the leached solution confirms the role of $MnCo₂O₄$ NPs in the peroxidase-like activity and the activity is not due to leached ions. **NJC**

Paper NJC

intercept values of Lineweaver–Burk reciprocal plots (Fig. S18(a and b), ESI†). The K_m and V_{max} values for SiO₂@MnCo₂O₄-1 core–shell nanorattles are summarized in Table 4. Table 4 also gives the kinetic parameters for different metal oxide nanoparticles and core-shell NPs reported in the literature.^{5,54-60} The Michaelis–Menten constant (K_m) is inversely proportional to the catalyst's affinity towards a substrate; a smaller K_m value indicates higher affinity of a catalyst towards the substrate.⁵⁴ The $K_{\rm m}$ and $V_{\rm max}$ values for SiO₂@MnCo₂O₄-1 core–shell nanorattles towards TMB are 0.032 mM and 1.596 \times 10^{-8} Ms $^{-1},$ respectively. The K_{m} and V_{max} values for SiO₂@MnCo₂O₄-1 core–shell nanorattles towards H_2O_2 are 2.7 mM and $0.532\,\times\,10^{-8}$ Ms $^{-1}$, respectively. The reported $K_{\rm m}$ and $V_{\rm max}$ values for $MnCo₂O₄$ nanoparticles towards TMB are 0.063 mM and 2.17 \times 10⁻⁵ Ms⁻¹, respectively.⁵¹ For the natural peroxidase enzyme (HRP), the reported K_m and V_{max} values towards TMB are 0.434 mM and 10 \times 10^{-8} Ms $^{-1}$ and towards $\rm H_2O_2$, the values are 3.70 mM and 8.71 \times 10 $^{-8}$ Ms $^{-1}$, respectively. 55 The observed K_m value for SiO₂@MnCo₂O₄-1 nanorattles towards TMB, in the present study, is smaller than that of $MnCo₂O₄$ nanoparticles and natural peroxidase enzyme (HRP). These results indicate high affinity of $SiO_2@MnCo_2O_4$ -1 core–shell nanorattles towards TMB with better peroxidase-like activity. **Paper**

Mechanism of peroxidase-like activity of SiO_2 @MnCo₂O₄ nanorattles

Fig. 8 shows the mechanism for the peroxidase-like activity of $SiO₂(\mathfrak{D}MnCo₂O₄)$ nanorattles. In the first step, adsorption of tetramethylbenzidine (TMB) molecules occurs on the surface of SiO_2 @MnCo₂O₄ nanorattles. This promotes nitrogen electron pair donation from the $NH₂$ groups of TMB towards the surface of $SiO_2@MnCo_2O_4$, resulting in high electron density over SiO₂@MnCo₂O₄.^{31,54,61} The SiO₂@MnCo₂O₄ core–shell nanorattles reduce H_{2}O_{2} into OH $^{-}$ and OH $^{\bullet}$ species. The OH $^{-}$ and OH^{\bullet} species facilitate the oxidation of TMB into TMB \bullet ^{\bullet} (a blue-colored CT complex). The rattle-like hierarchical structure of MnCo₂O₄ NPs present on the surface of $SiO₂$ spheres eases

Fig. 8 Proposed mechanism of peroxidase-like activity of $SiO₂$ @Mn-Co2O4 core–shell nanorattles using TMB as a substrate.

interaction between tetramethylbenzidine and the catalytic active centers (Mn^{2+}) and Co^{2+}) leading to improved peroxidase-like activity of the $SiO_2@MnCo_2O_4$ nanorattles.

In the current study, high surface area and rattle-like morphology of $SiO_2@MnCo_2O_4$ lead to enhanced peroxidase-like activity. The higher peroxidase-like activity of $SiO_2@MnCo_2O_4$ -1 compared to the other samples is attributed to its high surface area (356 m² g⁻¹). The SiO₂@MnCo₂O₄ core-shell nanorattles, synthesized in the current study, exhibit high surface area due to their rattle-type porous morphology. The high surface area of the SiO_2 @MnCo₂O₄ core–shell nanorattles is helpful for enhanced peroxidase-like activity. The rattle-type porous nature of hierarchical MnCo₂O₄ NPs on the surface of $SiO₂$ spheres provides less steric hindrance for the TMB molecules to interact with the catalytic centres (Mn^{2+}) and Co^{2+} .^{62,63} This promotes electron transfer from the $SiO_2@MnCo_2O_4$ core-shell nanorattles towards H_2O_2 resulting in faster chemical reduction of H_2O_2 .

Fig. S19 (ESI†) shows the fluorescence spectra for the detection of OH. radicals produced during the peroxidase-like activity. Terephthalic acid (probe molecule, λ_{exc} = 315 nm) produces fluorescent 2-hydroxyterephthalic acid (λ_{em} = 425 nm) on reacting with hydroxyl radicals. It can be noted that the fluorescence intensity increases with time due to increasing production of hydroxyl radicals. The PL results suggest the role of hydroxyl radicals in the peroxidase-like activity of $SiO_2@MnCo_2O_4$ nanorattles.

Detection of H_2O_2 using SiO₂@MnCo₂O₄ nanorattles

 $SiO₂@MnCo₂O₄$ core–shell nanorattles were used for the detection of H_2O_2 using peroxidase-like activity. A calibration plot (Fig. S20, ESI†) was recorded for $SiO_2@MnCo_2O_4$ -1 with varying concentration of H_2O_2 (linear range = 0.05 mM to 1 mM). The equation given below was used for determining the limit of detection (LOD) of H_2O_2 .

Limit of detection = $3 \times$ (Standard deviation due to blank/ Slope)

The standard deviation was estimated by recording the absorption spectra of a blank solution (*i.e.* $[H_2O_2] = 0$) three times. The slope was calculated from the absorbance ($\omega_{\text{max}} =$ 652 nm) versus $[H_2O_2]$ plot (Fig. S20(b), ESI†). The estimated LOD value for H_2O_2 using $SiO_2@MnCo_2O_4$ core–shell nanorattles is 0.083 mM and it is comparable with that reported in the literature.58,63

Conclusions

The current work demonstrates a simple and cost-effective synthetic strategy to synthesize $SiO_2@MnCo_2O_4$ core-shell nanorattles via calcination of SiO_2 @MnCo-LDH precursors at 500 °C. MnCo₂O₄ NPs deposit on the surface of $SiO₂$ spheres creating a hollow space (void) between the core and shell. The $\left[\text{Mn}^{2+}\text{:}Co^{2+}\right]$ ratio affects thickness of the MnCo₂O₄ shell and void distance between the core $(SiO₂)$ and the shell $(MnCo₂O₄)$. XRD results confirm the formation of $MnCo₂O₄$ NPs in the $SiO₂(@MnCo₂O₄ samples. FESEM and TEM analyses show$ nanorattle-like morphology of all the $SiO_2@MnCo_2O_4$ samples. The mean shell thickness and void distance between the $SiO₂$ core and $MnCo₂O₄$ shell in the $SiO₂@MnCo₂O₄$ core-shell nanorattles vary from 38 \pm 8 nm to 60 \pm 12 nm and 16 \pm 3 nm to 30 \pm 6 nm, respectively. BET measurements indicate higher surface area of SiO₂@MnCo₂O₄ core-shell nanorattles $(278 \text{ m}^2 \text{ g}^{-1}$ to 356 m² g⁻¹) compared to the constituents. XPS analysis confirms the presence of Si^{4+} , Mn^{2+} , Co^{2+} , Mn^{3+} , Co^{3+} , and O^{2-} in the SiO $_2$ @MnCo $_2$ O $_4$ nanorattles. Magnetic measurements indicate paramagnetic and superparamagnetic behavior of SiO_2 @MnCo₂O₄ nanorattles at 300 K and 5 K, respectively. The $SiO_2@MnCo_2O_4$ nanorattles exhibit better peroxidase-like activity than pure $MnCo₂O₄$ NPs and horseradish peroxidase. The peroxidase-like activity of the core–shell nanorattles can be useful for several sensing applications, such as the detection of glucose, H_2O_2 , ascorbic acid, hydroquinone, protein, and dopamine. **FIGURE 11**
