Emerging trends in aerogel technology for sensing and biosensing applications

 Aneesh Koyappayil,^a Gopi Karuppaiah,^a Sachin Ganpat Chavan,^a Anna Go,^a Hyung Chul Kim^{*b} and Min-Ho Lee ^{*a}

Aerogels have gained attention for their unique physicochemical attributes, including their lightweight structure, adjustable porosity, expansive surface area with customizable functionalities, and notable biocompatibilities. A crucial factor in employing aerogels within biosensors is the improvement in sensitivity, selectivity, and response speed due to their effective interactions with biological targets. Recent advancements in aerogel synthesis, particularly with the incorporation of 0D, 1D, and 2D materials, have significantly enhanced the performance of aerogel-based sensors through a synergistic effect. An increasing array of aerogels has been documented for biosensing purposes and as electrode materials in smart sensors that aim to detect biomolecules for biomedical applications. Various synthesis techniques for aerogels and their composites have emerged. Aerogel composites that feature nanoparticles and 2D/3D materials are noted for their relevance in sensing applications. Discussions surrounding these materials often focus on their use in biosensors, smart sensors, microfluidics, and innovative devices. This review seeks to underline new trends in aerogel technology for biosensing applications, concentrating on advancements in synthesis methods, the creation of novel aerogel composites, and aerogel-based sensors aimed at biosensing, biomarker detection, smart sensors, wearable technology, and microfluidic devices as well as the biocompatibility and sustainability of aerogels and their composites. The review also highlights how aerogels enhance the selectivity, sensitivity, and efficiency of biosensors. The latest developments in smart aerogels are opening opportunities for real-time biomolecule monitoring. Additionally, their integration with microfluidic devices has led to the creation of portable, cost-effective lab-on-a-chip devices, which support rapid diagnostics in cutting-edge biosensing technologies.

1. Introduction

Aerogels have captivated the scientific community due to their remarkable physical properties and are often referred to as ‘frozen smoke’ because of their composition and lightweight appearance. In recent years, there has been an increasing trend in aerogel-based research, as evidenced by the exponential growth in the number of publications (Fig. 1A). The density of aerogels can be as low as 3 kg m⁻³,¹ and their thermal conductivity is the lowest of any solids (0.014 W m⁻¹ K⁻¹ at room temperature).² Aerogel synthesis was first reported by Samuel Stevens Kistler in 1931, where silica aerogel was synthesized from silica jelly.³ Kistler's studies established aerogel as a potential catalyst and insulator. The initial synthesis routes to aerogels were tedious and time-consuming until Teichner *et al.* proposed a relatively quicker synthesis

route using tetramethyl orthosilicate as a precursor by employing a sol-gel process.⁴ In the early 1940s, Monsanto Corporation commercialized silica aerogel under the brand name Santocel.⁵ However, the high production cost largely inhibited widespread industrial applications. The late 1960s and early 1970s saw a resurgence in aerogel research, leading to faster synthesis routes that simplified the sol-gel process.⁶ Porous alumina aerogels were introduced in the 1970s.⁷ In the 1980s, the supercritical drying process using liquid carbon dioxide was introduced for safer and less energy-intensive aerogel synthesis.⁸ This method was adopted for the synthesis of organic aerogels, and the term ‘carbogels’ was coined for CO₂-dried organic aerogels.⁹ Due to the low refractive index, aerogel was used for the detection of Cherenkov radiation.¹⁰ The 1990s experienced a broad expansion in the types and applications of aerogels. Titania aerogels were introduced, and the sol-gel process was refined with polyethoxydisiloxane and tetraethoxysilane.¹¹ Small-angle scattering techniques advanced the understanding of aerogel structure. In the early 2000s, the Glenn Research Center of NASA developed polymer-reinforced silica aerogels with enhanced strength and translucency.¹²

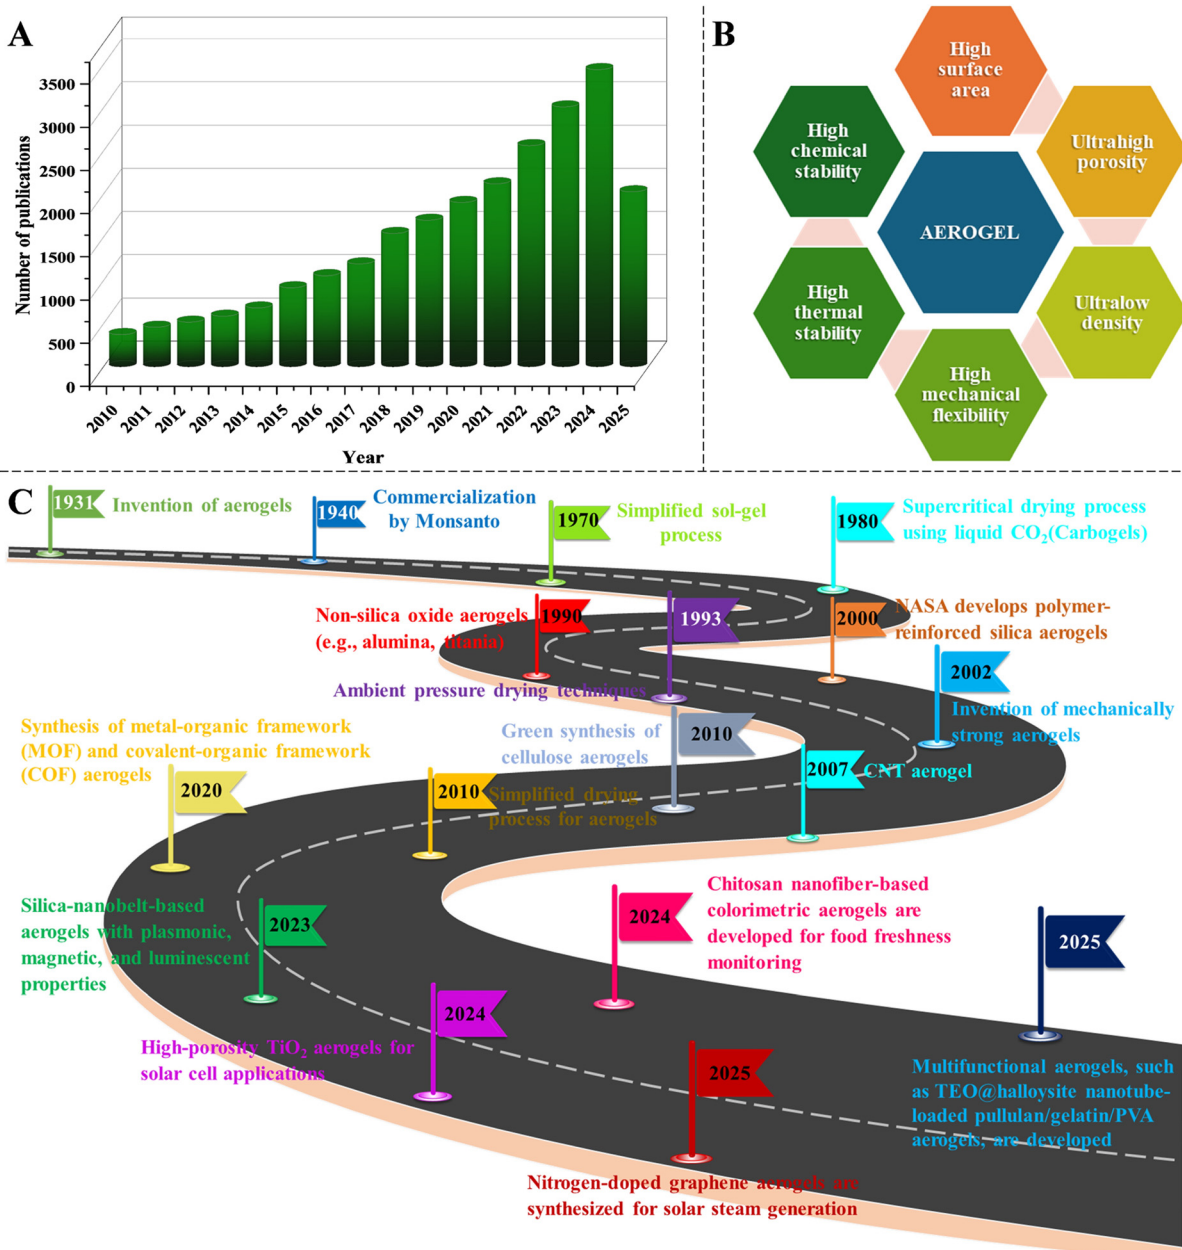

Fig. 1 (A) Year-wise number of publications from 2010 to 2025 based on the Scopus database using the search term 'aerogel' (accessed on 11th June 2025). (B) Advantages of aerogels over conventional sensing materials. (C) Roadmap of the advancements in aerogel technology.

These aerogels were successfully used as insulating materials in Mars rovers. The 2000s saw a growing interest in aerogel research for environmental applications, such as pollutant removal. In the 2010s, green synthesis was reported for cellulose aerogels, significantly reducing the cost of aerogel synthesis. The period from 2010 is regarded as the age of multifunctional aerogels. Aerogels such as MOF aerogels,^{13–15} MXene aerogels,^{16–18} graphene/graphene oxide aerogels,^{19–22} heteroatom-doped aerogels,^{23–25} and nanoparticle-incorporated aerogels^{26–28} have been synthesized and applied to diverse applications. Recently, the focus of aerogel-based research has shifted towards composite,²⁹ sustainable,³⁰ and biodegradable aerogels.³¹ Aerogels have been utilized in smart devices for

healthcare³² and environmental remediation.³³ Studies have concentrated on one-pot and green synthesis of aerogels for convenience and reduced environmental impact.^{34–36}

Being a distinguished category of aerogels, noble metal-based aerogels³⁷ outperform traditional aerogels like silica, carbon, and metal oxide-based materials by combining the natural catalytic and electronic properties of noble metals with high surface area and porosity. Noble metal aerogels demonstrate high atomic efficiency and have several advantages, such as hierarchical porosity, ultralow mass density, good conductivity, and chemical properties that enhance interactions with biomolecules and support natural enzymes.³⁸ These aerogels have been applied as supports for

natural enzymes and as nanozymes in biosensors and also find applications in advanced catalysis,³⁹ energy storage,⁴⁰ and biomedical fields,⁴¹ although their high cost remains a limiting factor. For biosensing, the plasmonic and electrical features of noble metals enable highly sensitive detection of analyte molecules. Their high conductivity and porosity improve sensor performance, making them ideal for electrode materials. The biocompatibility of these aerogels supports biomedical applications, such as drug delivery and tissue engineering. Additionally, their optical properties are employed in photonics and surface-enhanced Raman spectroscopy. The corrosion resistance and chemical stability of noble metal-based aerogels ensure reliable performance in harsh environments. Furthermore, their tunable, self-supporting structure eliminates the need for additional support materials, thereby reducing material losses. However, current research primarily focuses on Au, Ag, Pt, and Pd as single-metal noble aerogels for biosensing, with other noble metals, such as ruthenium (Ru) and iridium (Ir), being rarely studied.

Aerogels possess several advantages over conventional sensing materials (Fig. 1B). In this context, this review discusses the emerging trends in aerogel synthesis, biosensing applications, smart sensing, environmental impact, and futuristic aspects of aerogels. The significant achievements in this field are illustrated in Fig. 1C.

2. Classification and properties of aerogels

Aerogels are classified based on origin, appearance, synthesis, microstructure, and drying process (Fig. 2). They are primarily categorized according to their composition,

Fig. 2 Classification of aerogels based on origin, synthesis, microstructure, appearance, and drying process.

which includes three main categories: organic aerogels, inorganic aerogels, and hybrid aerogels. Each type of these aerogels is characterized by distinct materials and properties, making them suitable for various applications. Organic aerogels are made from carbon-based materials, inorganic aerogels consist of metal oxides or other inorganic compounds, and hybrid aerogels combine both organic and inorganic components to leverage the benefits of each material. Organic aerogels are considered to be among the first types of aerogels ever created. The pioneering work in organic aerogel production was conducted by Samuel Kistler in 1932, when he successfully prepared aerogel using pectin as the primary material. The structure of organic aerogels consists of a three-dimensional framework predominantly composed of organic polymers, which bestow them with their unique properties. Based on the synthesis route, aerogels are classified into conventional and unconventional aerogels. The microstructure-based classification of aerogels, *viz.*, microporous and macroporous, is particularly useful in sensing applications. The classification based on appearance is film, powder, and fiber, whereas, based on the drying process, aerogels are further classified as aerogel, xerogel, cryogel, and lyogel.⁴²

Over the years, a variety of aerogels and their composites have been synthesized and reported in scientific literature. Each of these aerogels offers distinct characteristics, making them suitable for diverse applications in fields such as insulation, filtration, energy storage, and sensors. The continuous development of new aerogels has expanded the potential of this class of materials in both industrial and scientific research.

3. Nanostructured aerogels for biosensing

The advent of nanostructured aerogels has paved the way for new biosensing opportunities. By integrating nanoparticles such as gold, silver, carbon nanotubes, and graphene into these aerogels, researchers enhance the material's electrical, optical, and thermal properties. These advanced aerogels achieve exceptional success in detecting a range of biomolecules, such as proteins, nucleic acids, and toxins. For instance, gold nanoparticle-enhanced aerogels have proven effective in surface plasmon resonance biosensors, where the biomolecule's interaction with the sensor surface induces a measurable change in the refractive index. Similarly, graphene-based aerogels, renowned for their exceptional conductivity, are being explored for electrochemical biosensing applications, which rely on electron transfer between the analyte and the electrode surface. Aerogel-based electrochemical biosensors exhibit high sensitivity due to their capability to detect slight variations in analyte concentration. This increased sensitivity stems from the porous nature of aerogels, which possess a large surface area. The tunable porosity of these aerogels facilitates the immobilization of biological recognition elements, such as

Table 1 Literature reports on aerogel-based biosensors

Type of aerogel	Sensor composition	Target analyte	Sensing mechanism	Detection range	LOD	Ref.
Graphene aerogel	Graphene aerogel, gold nanoparticles, cytochrome <i>c</i> (Cyt <i>c</i>)	Hydrogen peroxide	Electrochemical detection <i>via</i> direct electron transfer between Cyt <i>c</i> and the electrode for H ₂ O ₂ reduction (amperometry)	10–9740 μM	1.1 μM	55
Graphene aerogel	3D graphene aerogel@GOx microfluidic biosensor	Glucose	Electrochemical detection <i>via</i> amperometric measurement of H ₂ O ₂	1000–18 000 μM	870 μM	45
Graphene aerogel	3D MoS ₂ /graphene aerogel (MGA), glucose oxidase	Glucose	Enzyme-based oxidation of glucose by GOx, generating H ₂ O ₂ , measured by amperometry	2000–20 000 μM	290 μM	46
Graphene aerogel	Graphene aerogel, gold nanoparticles, glucose oxidase	Glucose	Glucose oxidation by GOD generates H ₂ O ₂ , which is monitored by current–time (<i>I</i> – <i>t</i>) curves	50 000–450 000 μM	0.597 μM	54
Graphene aerogel	N-doped graphene aerogel/gold nanostar	Double-stranded DNA	Electrochemical detection <i>via</i> DPV	100 fg ml ⁻¹ –10 ng ml ⁻¹	39 fg ml ⁻¹	72
Nanosilica-functionalized graphene oxide aerogel	Insulin aptamer (IGA3), oligonucleotide-functionalized gold nanoparticles (ssDNA-AuNPs), and SiO ₂ @GOAG.	Insulin	Chemiluminescence: insulin binds to the IGA3 aptamer, releasing ssDNA-AuNPs, which catalyze the luminol–H ₂ O ₂ chemiluminescent reaction	7.5 × 10 ⁻⁶ –0.005 μM	1.6 × 10 ⁻⁶ μM	71
UiO-66-NH ₂ aerogel	TCP(Fe)@UiO-66-NH ₂ aerogel immobilized with glucose oxidase	Glucose	Colorimetric sensing through a cascade reaction involving GOx and iron porphyrin	10–800 μM	0.0003 μM	47
Poly(vinyl alcohol) aerogel	Glucose oxidase and hemin immobilized in amphiphilic PVA aerogel	Glucose	Colorimetric detection based on the oxidation of TMB, catalyzed by GOx and hemin	0–1600 μM	11.4 μM	48
Carbon aerogel	CAs doped with iron and iron carbide (Fe/FeC), derived from algae residue, modified GCE	Dopamine	Electrochemical sensing <i>via</i> electro-oxidation of DA, with the current–time (<i>I</i> – <i>t</i>) response, enhanced electron transfer using CAs-Fe/GCE	0.01–200 μM	0.0033 μM	68
Co ₃ O ₄ /rGO aerogel	Co ₃ O ₄ /3D MX-rGO modified GCE	Dopamine	Electrochemical detection <i>via</i> differential pulse voltammogram	0.1–300 μM	0.04 μM	67
Mo–W–O/graphene aerogel	Mo–W–O/GA modified GCE	Tyrosine Dopamine	Electrochemical detection <i>via</i> differential pulse voltammogram	0.001–478 μM 0.001–448 μM	0.0014 μM 0.0008 μM	70
Core–shell AgNWs@PB aerogel	Ag nanowires (AgNWs), Prussian blue (PB), uricase, BSA, glutaraldehyde	Uric acid	PB nanoparticles catalyze H ₂ O ₂ oxidation from the uricase reaction and chronoamperometry (CA) measured at 0.3 V	10–3000 μM	0.050 μM	63
Ni–Co and Pd–Co aerogel	Urate oxidase enzyme-immobilized Ni–Co and Pd–Co aerogel	Uric acid	Amperometric determination of uric acid on enzyme-incorporated aerogel electrode	0–250 μM	5.4 ± 0.3 μM	65
Graphene oxide aerogel	Pd–Fe nanoparticle-decorated 3D graphene oxide aerogel	Ascorbic acid Dopamine Uric acid 8-Hydroxyguanine Guanine Adenine Thymine Cytosine	Electrochemical detection <i>via</i> differential pulse voltammogram	5.0–1750 μM 0.25–100 μM 0.5–500 μM 0.5–375 μM 0.5–500 μM 0.5–500 μM 5.0–1500 μM 5.0–1500 μM	0.5537 μM 0.0018 μM 0.0696 μM 0.0432 μM 0.0429 μM 0.0723 μM 0.0572 μM 0.3184 μM	74
Carbon aerogel	Pd nanoparticle-supported carbon aerogel	Dopamine Melatonin	Electrochemical detection <i>via</i> differential pulse voltammogram	0.01–100 μM 0.02–500 μM	0.0026 μM 0.0071 μM	73

biomass precursors and applied for the fluorescence and nonenzymatic electrochemical determination of glucose

(Fig. 4A). The dual-mode detection mode of this sensor enhanced the versatility and reliability of glucose detection.

Additionally, nitrogen doping significantly improved the properties of the carbon-based aerogel, boosting its conductivity and electrocatalytic performance while maintaining cost-effectiveness and scalability for large-scale manufacturing. The sensor was able to detect $3.1 \mu\text{M}$ of glucose fluorometrically and $0.5 \mu\text{M}$ electrochemically. Yue *et al.*⁸³ achieved fast direct electron transfer of glucose oxidase from carbon nanofiber aerogels (Fig. 4B). Here, the aerogel was synthesized from a coconut matrix, adding sustainability to the synthesis route. In addition, the aerogel possessed ultralight low density, high porosity, and high specific surface area. Song *et al.*⁵¹ reported atomically dispersed cobalt on nitrogen-doped carbon aerogels. The 3D framework of the aerogel efficiently dispersed the Co atoms, and the single cobalt atom sites were then applied for nonenzymatic electrochemical oxidation of glucose (Fig. 4C). The sensor reported a detection limit of $0.1 \mu\text{M}$ and was applied for the detection of glucose from saliva and serum samples. Synergistic effects of Pd and Cu for glucose oxidation were reported by Li *et al.*⁵³ on Pd-Cu bimetallic

aerogels (Fig. 4D). The bimetallic aerogel was synthesized using a simple self-assembly reduction technique and was able to oxidize glucose at a low potential (0 V vs. Ag/AgCl) and neutral pH.

Dong *et al.*⁵² reported a heterojunction interface of metal-organic framework (Co-MOF) and gold, which promoted electron transfer and increased conductivity for enhanced glucose detection (Fig. 4E). Here, the Co-MOF aerogel was synthesized by a hydrothermal method, and gold nanoparticles were *in situ* loaded on it. The Co-MOF/Au-modified glassy carbon electrode was able to detect glucose with high sensitivity ($206 \mu\text{A cm}^{-2} \text{ mM}^{-1}$) and a low limit of detection (10 nM). Another compelling application of noble metal-based aerogels for glucose detection was described by Fang *et al.*⁴⁹ Here, a low-cost bismuth-anchored Au aerogel was synthesized by simple precipitation followed by supercritical CO_2 drying. The Au-Bi aerogels greatly enhanced glucose oxidation owing to the synergistic effect between gold and bismuth (Fig. 4F)

4.3. Dopamine detection on aerogel-based sensors

Monitoring the accurate concentration of neurotransmitters is essential for understanding brain function and diagnosing various mental disorders.^{84–86} Several aerogels have been reported for the sensitive determination of the monoamine neurotransmitter dopamine. The secretion of dopamine from living cells is instantaneous, necessitating sensors with high sensitivity and fast response times for monitoring. Zou *et al.*⁸⁷ reported nitrogen-doped graphene aerogel/ Co_3O_4 composite-modified electrodes for the sensitive real-time monitoring of dopamine secreted from living cells under K^+ stimulation (Fig. 5A). The aerogel-modified electrode benefits from the high surface area, conductivity, and catalytic activity, showing a wide linear range for dopamine detection. Incorporating nitrogen-doped graphene aerogels with cobalt oxide (Co_3O_4) nanoparticles enhances the sensor's electrocatalytic activity, sensitivity, and selectivity for dopamine detection. This advancement has significant implications for neurological diagnostics and neurobiological research. Potential applications include personalized medicine for Parkinson's disease and advanced neurochemistry studies, marking a major step forward in tracking neurotransmitter dynamics in living systems. Qi *et al.*⁶⁷ reported a MXene-based aerogel for the sensitive

detection of dopamine (Fig. 5B). In this research, Co_3O_4 /MXene-rGO aerogel was synthesized as the electrode material. Within the composite, the MXene-rGO aerogel prevented the aggregation of Co_3O_4 particles and provided abundant active sites, resulting in enhanced electrocatalytic activity towards dopamine. The sensor could detect dopamine in the range of 0.1–300 μM with a detection limit of 40 nM. Mariyappan *et al.*⁷⁰ reported the synthesis of Mo-W-O nanowire intercalated graphene aerogels through hydrothermal and freeze-drying methods as an electrode material for the simultaneous determination of dopamine and tyrosine (Fig. 5C). The Mo-W-O/GA-modified GCE was applied for the rapid determination of dopamine and tyrosine in the presence of other interfering molecules. The reported sensor parameters were 0.001–448.0 μM and LOD of 0.8 nM for dopamine as well as 0.001–478.0 μM and LOD of 1.4 nM for tyrosine. Another interesting aerogel-based dopamine sensor was reported by Feng *et al.*⁶⁶ In this work, the simultaneous determination of dopamine (DA), ascorbic acid (AA), and uric acid (UA) was achieved on holey nitrogen-doped graphene aerogel (Fig. 5D). This aerogel significantly reduced the overpotential for the electro-oxidation of DA, AA, and UA, contributing to increased current density and a significantly large peak potential difference (Fig. 5E).

4.4. Aerogel-based detection of other biomolecules

Ascorbic acid or vitamin C acts as a potent antioxidant and protects cells from free radical damage.⁸⁹ It is also crucial for various bodily functions, such as wound healing, immune system support, collagen formation, and iron absorption.^{90,91} Wang *et al.*⁹² synthesized carbon nanorod-assembled meso-macroporous carbon aerogels from apple fruit and applied them for the amperometric determination of ascorbic acid and hydrogen peroxide (Fig. 6A). The carbon biomass derived from apples was characterized by a high density of defective edge sites and a large surface area, which greatly enhanced the electron transfer between analytes and the electrode surface. This study presents a significant advancement in sustainable electrochemical sensing by introducing an eco-friendly and cost-effective method to synthesize functional carbon aerogels from natural biomass. This technique avoids the use of toxic precursors and intricate templating processes. The resulting carbon aerogels feature a hierarchical mesoporous and macroporous structure made of interconnected carbon nanorods, which offer a high surface area, improved electrical conductivity, and efficient ion diffusion pathways. These structural characteristics lead to superior electrochemical performance, enabling highly sensitive and selective detection of ascorbic acid and hydrogen peroxide. The findings highlight a direct link between green chemistry principles and the development of

functional materials. Ferrag *et al.*⁷⁴ reported the simultaneous detection of eight biomolecules on Pd-Fe nanoparticle-decorated graphene oxide aerogel. In this research, the bimetallic aerogel was immobilized on a glassy carbon electrode and used for the simultaneous voltammetric determination of ascorbic acid, cytosine, 8-hydroxyguanine, guanine, dopamine, uric acid, adenine, and thymine (Fig. 6B). Interestingly, this was the first simultaneous determination of eight biomolecules on a single electrode. The electrode was also tested for recovery studies from real samples, yielding satisfactory results. The hormone melatonin influences the body's internal clock and plays a crucial role in regulating sleep.⁹³ It also impacts other bodily functions such as mood disorders, puberty timing, immune regulation, and transplantation.⁹⁴ Rajkumar *et al.*⁷³ synthesized a palladium-supported carbon aerogel for the electrochemical determination of melatonin and dopamine (Fig. 6C). Here, a simple microwave reduction route is used for the synthesis of Pd/carbon aerogel composite with a large surface area and pore volume. The Pd/carbon aerogel-modified electrode was applied for the individual and simultaneous determination of melatonin and dopamine with a wide linear range (0.01–100 μM and 0.02–500 μM) and a low detection limit of 0.0026 and 0.0071 μM for dopamine and melatonin, respectively. Uric acid is linked to several health conditions, such as hyperuricemia, cardiovascular

Copyright 2025, Elsevier.

problems, hypercholesterolemia, hypertension, Lesch-Nyhan syndrome, and renal dysfunction.⁹⁵ At physiological pH, biomolecules exist in their functional state, and the determination of biomolecules at physiological pH is considered advantageous. Ruiz-Guerrero *et al.*⁶⁵ reported the physiological pH electrochemical determination of uric acid on urate oxidase enzyme-immobilized Ni-Co and Pd-Co aerogels (Fig. 6D). The aerogel-modified electrodes exhibited improved performance compared to the electrodes modified with the urate oxidase enzyme.

4.5. Aerogel-based sensors for other prognostic biomarkers

Biomarker detection requires sensitive detection platforms due to the low concentrations of these biomolecules.⁹⁶ Electrochemical techniques are often acknowledged as cutting-edge technology, and the heightened sensitivity provided by aerogel-based sensing platforms is often preferred for biomarker detection (Fig. 7). Aerogels with high porosity and surface area enhance the interaction between the biomolecules and the sensing materials, resulting in sensitive and selective detection of the biomarkers. Biomarkers such as carcinoembryonic antigen (CEA),^{97–100} tumor-derived exosomes,⁹⁹ prostate-specific antigen (PSA),^{101,102} carbohydrate antigen 15-3 (CA 15-3),¹⁰³ alpha-fetoprotein (AFP),^{97,99} human interleukin-6 (IL-6),¹⁰⁴ ATP5O,

CANX genes,¹⁰⁵ human neutrophil elastase (HNE),¹⁰⁶ immunoglobulin G (IgG),¹⁰⁷ and platelet-derived growth factor-BB (PDGF-BB),¹⁰⁸ have been analyzed using aerogel-based sensing platforms (Table 2).

Carcinoembryonic antigens are a serum biomarker that is elevated in many types of malignancies, including mucinous ovarian cancer, thyroid cancer, colorectal cancer, and breast cancer.¹⁰⁹ CEA biomarker detection is used as an auxiliary tool, combined with pathology and imaging techniques for cancer diagnosis. Majeed *et al.*⁹⁸ described reduced graphene oxide, terbium@amine-functionalized fibrous silica (Tb@FNS-NH₂), and β -cyclodextrin-modified screen-printed carbon electrodes for the detection of CEA (Fig. 7C). This study addresses the persistent challenge of biofouling in clinical sensing by developing a nanocomposite interface with low biofouling properties. The integration of terbium ions enables a ratiometric electrochemical detection approach, which provides internal calibration to minimize background interference. The design involving the carboxylic groups in β -CD-COOH, rGO aerogel and Tb@FNS-NH₂ achieves high surface area, efficient electron transport, and enhanced antibody immobilization, resulting in improved sensitivity, selectivity, and stability for carcinoembryonic antigen (CEA) detection. The immunosensor reported a wide dynamic range (10 fg ml^{-1} to 1.0 ng ml^{-1}) and a low limit of detection (6.0 fg ml^{-1}) for CEA. Prostate-specific antigen

Copyright 2018, Springer.

(PSA) is a protein biomarker secreted by the epithelial cells of the prostate.¹¹⁰ A high PSA level may indicate prostate cancer, and PSA has been widely utilized for the detection and diagnosis of prostate cancer.¹¹¹ Hu *et al.*¹⁰¹ reported an aptamer-based electrochemical PSA detection platform using 3D graphene aerogels (Fig. 7A). In this work, Au nanoparticles were introduced into the aerogels to improve the sensitivity of detection. Impedance spectroscopy was then used as an electrochemical technique for the sensitive detection of PSA in the dynamic range of 0.05 to 50 ng ml⁻¹ with a limit of detection of 0.0306 ng ml⁻¹. Carbohydrate antigen 15-3 (CA 15-3) is often used as a biomarker for estimating the progression of breast cancer.¹¹² Jia *et al.*¹⁰³ immobilized CA15-3 antibody on graphene aerogel and polymeric β-cyclodextrin-modified electrode for the voltammetric determination of CA 15-3 (Fig. 7D). In this work, the large effective surface area and high electrical conductivity of graphene aerogel resulted in high antibody loading and strong voltammetric response for CA 15-3. The immune sensor achieved a linear response range of 0.1 mU ml⁻¹ to 100 U ml⁻¹ and a lower detection limit of 0.03 mU

ml⁻¹. Serum platelet-derived growth factor BB (PDGF-BB) is applied as a potential biomarker for the assessment of liver fibrosis in hepatitis B patients,¹¹³ for differentiating bipolar disorders,¹¹⁴ identifying oxidative stress in inflammatory bowel disease,¹¹⁵ and fulminant hepatic failure,¹¹⁶ whereas urine PDGF-BB may be applied for the early diagnosis of prostate cancer.¹¹⁷ Fang *et al.*¹⁰⁸ described a sandwich electrode based on a dual aptamer-modified MoS₂/carbon aerogel electrode for the detection of PDGF-BB (Fig. 7B).

4.6. Aerogel-based wearable and smart biosensors

Wearable biosensors address the limitations of conventional biosensors and demonstrate significant potential for the personalized treatment of physical conditions.^{119,120} Electrochemical techniques are valued for their high selectivity,¹²¹ simplicity,¹²² and sensitivity,¹²³ making them popular in the development of wearable sensors.¹²⁴ Aerogel-based non-invasive wearable sensors have garnered attention due to the inherent benefits of aerogels along with their ability to minimize the discomfort associated with invasive

Table 2 Recent reports on aerogels for biomarker detection

Type of aerogel	Sensor composition	Target analyte	Sensing mechanism	Detection range	LOD	Ref.
Graphene aerogel	3D graphene–Au aerogels on glassy carbon electrode (GCE); Ab1 antibody; CZTS NCs as the label	Carcinoembryonic antigen	Electrochemical detection using H ₂ O ₂ reduction with CZTS NCs, measured by amperometry	0.5 pg ml ⁻¹ to 20 ng ml ⁻¹	0.15 pg ml ⁻¹	100
Graphene aerogel	Nano-PEDOT-graphene aerogel composite with AuNPs, GCE	Prostate-specific antigen	Electrochemical Immunosensor: DPV is used for detection, with [Fe(CN) ₆] ^{3-/4-} as the redox	0.0001 to 50 ng ml ⁻¹	0.03 pg ml ⁻¹	118
Graphene aerogel	Pβ-CD/graphene aerogel nanocomposite and anti-CA 15-3 antibody	Carbohydrate antigen 15-3	Electrochemical immunosensor: DPV is used for detection, with [Fe(CN) ₆] ^{3-/4-} as the redox	0.1 mU ml ⁻¹ to 100 U ml ⁻¹	0.03 mU ml ⁻¹	103
Graphene aerogel	Graphene aerogel functionalized with specific antibodies in ITO	Alpha-fetoprotein, carcinoembryonic antigen, tumor cell-derived exosomes	Electrochemical immunosensor: electrochemical impedance spectroscopy (EIS) is used for detection, with [Fe(CN) ₆] ^{3-/4-} as the redox	AFP: 7.9 pg ml ⁻¹ to 10 μg ml ⁻¹ , CEA: 7.9 pg ml ⁻¹ to 500 ng ml ⁻¹ , exosomes: 10 to 10 ⁶ particles per μL	AFP: 7.9 pg ml ⁻¹ , CEA: 6.2 pg ml ⁻¹ , exosomes: 10 particles per μL	99
Graphene aerogel	Graphene aerogel/AuNPs/Nafion-modified SPE with aptamers	Prostate-specific antigen	Electrochemical immunosensor: EIS is used for detection, with K ₃ [Fe(CN) ₆]/K ₄ [Fe(CN) ₆] as the redox	0.05 to 50 ng ml ⁻¹	0.0306 ng ml ⁻¹	101
Graphene aerogel	rGO-carboxymethyl β-cyclodextrin (β-CD-COOH) and Tb@FNS-NH ₂ composite	Carcinoembryonic antigen	Electrochemical detection using [Fe(CN) ₆] ^{3-/4-} as a redox probe in SWV	10 fg ml ⁻¹ to 1.0 ng ml ⁻¹	6.0 fg ml ⁻¹	98
Graphene aerogel	Pd NP-functionalized Fe ₃ O ₄ -supported GA (FGA-Pd), Ru(bpy) ₃ ²⁺ , Au-FONDS	Prostate-specific antigen	Ru@FGA-Pd enhances electrochemiluminescence (ECL) efficiency <i>via</i> electrostatic interaction, with Pd NPs boosting electron transfer for signal amplification	0.0001 to 50 ng ml ⁻¹	0.056 pg ml ⁻¹	102
Silica aerogel	Amino silica aerogel and aminoalkylsilane	Human interleukin-6 (IL-6)	Sandwich immunoassay-based fluorescence detection (Cy5-labeled secondary antibody)	0.00001 to 10 000 ng ml ⁻¹	10 fg ml ⁻¹	104
Silica aerogel	Tetraethyl orthosilicate, ionic liquid, 3-glycidoxypropyltrimethoxysilane, mesoporous silica aerogel	DNA (ATP5O, CANX genes)	Fluorescence detection after DNA probe immobilization on the aerogel surface	0.00001 to 10 000 ng ml ⁻¹	0.00001 ng ml ⁻¹	105
Nanocellulose aerogels	Greige cotton, calcium thiocyanate, lithium chloride, fluorescent peptide substrate	Human neutrophil elastase	Enzyme activity detection through fluorescence emitted after peptide cleavage	0.02 to 0.1 U ml ⁻¹	0.13 units per ml	106
Cellulose nanofiber aerogel	CNF aerogel integrated into the lateral flow immunoassay strip between the conjugate pad and the nitrocellulose strip	Immunoglobulin G (IgG)	Lateral flow immunoassay	0.17 to 100 ng ml ⁻¹ (buffer) and, 4.6 to 100 ng ml ⁻¹ (serum)	0.01 ng ml ⁻¹ (buffer), 0.72 ng ml ⁻¹ (serum)	107
Carbon aerogel	MoS ₂ /CA, AuNPs, Apt1, Apt2, Fc-AuNPs	Platelet-derived growth factor BB (PDGF-BB)	Differential pulse voltammetry (DPV) is employed to detect the electrochemical signal from the Fc-labelled AuNPs	0.001 to 10 nM	0.3 pM	108
Carbon nanotube aerogel	Ethylenediamine-MWCNT aerogels, AuNPs, thionine (Thi), safranin O (SfO), capture antibodies (Cp-Ab1), SPCE	Alpha-fetoprotein, carcinoembryonic antigen	Square wave voltammetry (SWV): using Thi and SfO as distinguishable signal labels	0.005 to 1.0 ng ml ⁻¹ for both AFP and CEA	AFP: 0.0015 ng ml ⁻¹ , CEA: 0.0010 ng ml ⁻¹	97

body fluid monitoring. Chen *et al.*⁶⁴ reported N-doped reduced graphene oxide/Au-based dual-aerogel as an electrode material for a wearable uric acid sensor that utilizes sweat (Fig. 8A). This study represents a significant advancement in continuous wearable biosensing technology for personalized healthcare. The synthesized 3D aerogel provided a large electroactive surface area and efficient electron transfer pathways. The electrode showcased direct

electrooxidation of uric acid. The three-dimensional porous aerogel consisting of gold nanowires and N-doped graphene nanosheets (designated as N-rGO/Au DAs) offers rapid electron transfer, a large active surface, and ample access to the target. As a result, direct uric acid electro-oxidation occurs at the N-rGO/Au DAs with significantly greater activity than that of the individual gels (*i.e.*, Au and N-rGO). Furthermore, the resulting sensing chip demonstrated high

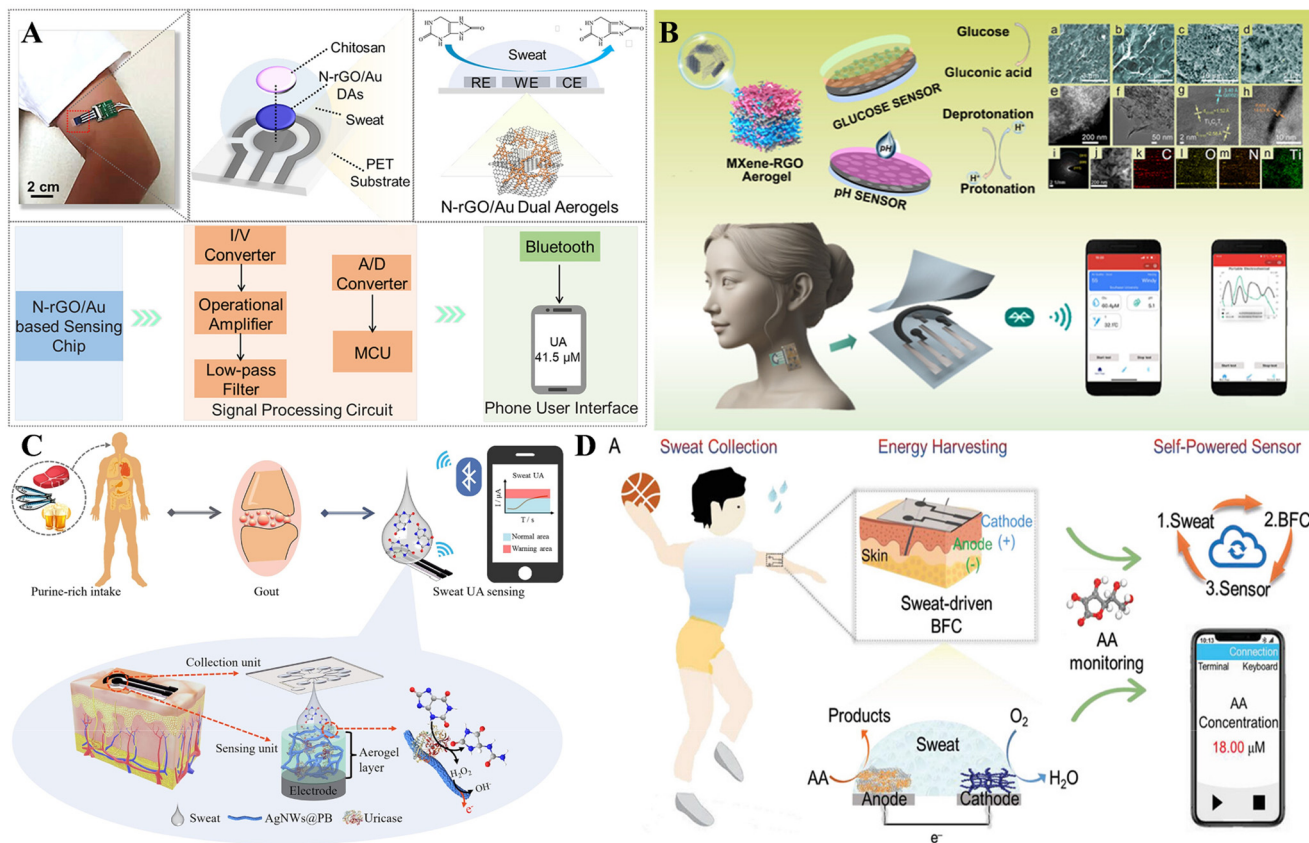

Fig. 8 (A) Schematics and working principle of N-doped reduced graphene oxide/Au aerogel-based nonenzymatic wearable uric acid sensor. Reproduced with permission from ref. 64. performance, excellent anti-interference capabilities, long-term stability, and remarkable flexibility for uric acid detection. With the addition of a wireless circuit, this wearable sensor is effectively utilized for the detection of uric acid from human skin. The results obtained are comparable to those assessed by high-performance liquid chromatography. This nonenzymatic aerogel biosensing platform shows great promise for the reliable monitoring of sweat metabolites and paves the way for metal-based aerogels to be used as flexible electrodes in wearable sensing.

Smart sensors capable of continuously monitoring glucose levels without restricting the user's mobility are crucial for diabetes management. Chen *et al.*¹²⁵ synthesized a 3D porous aerogel from Ti₃C₂T_x MXene and reduced graphene oxide as electrode material for the smart sensing of glucose from human sweat (Fig. 8B). The porous aerogel, which firmly anchored the glucose oxidase enzyme, reduced the electron transfer distance between the electrode surface and the enzyme's redox center. The sensor could detect pH and adjust to the pH fluctuations in sweat, thereby increasing the sensitivity of the dynamic glucose monitoring

by providing real-time pH calibration. The smart sensing platform holds promises for personalized fitness applications and health tracking. Jiang *et al.*⁶³ achieved Ag nanowires (AgNWs) and Prussian blue (PB) aerogel-based smart sensor for the detection of uric acid from sweat (Fig. 8C). Uric acid is produced in the human body through the metabolism of purine and is widely distributed throughout the body. Fluids such as blood, sweat, saliva, and urine contain varying amounts of uric acid. Since the human body cannot metabolize uric acid, it must be excreted through the kidneys, and the concentration of uric acid is closely related to potential diseases such as hypertension, kidney damage, gouty arthritis, and hyperuricemia.¹²⁶ The concentration of uric acid in sweat is extremely low and requires highly sensitive sensing platforms for the detection of uric acid from sweat. The aerogel-based smart sensor exhibited a wide linear range and high sensitivity for uric acid detection. The porous structure of the aerogel, along with a large active surface area and ample electron transfer pathways, facilitated the efficient diffusion of uric acid molecules and electrolytes,

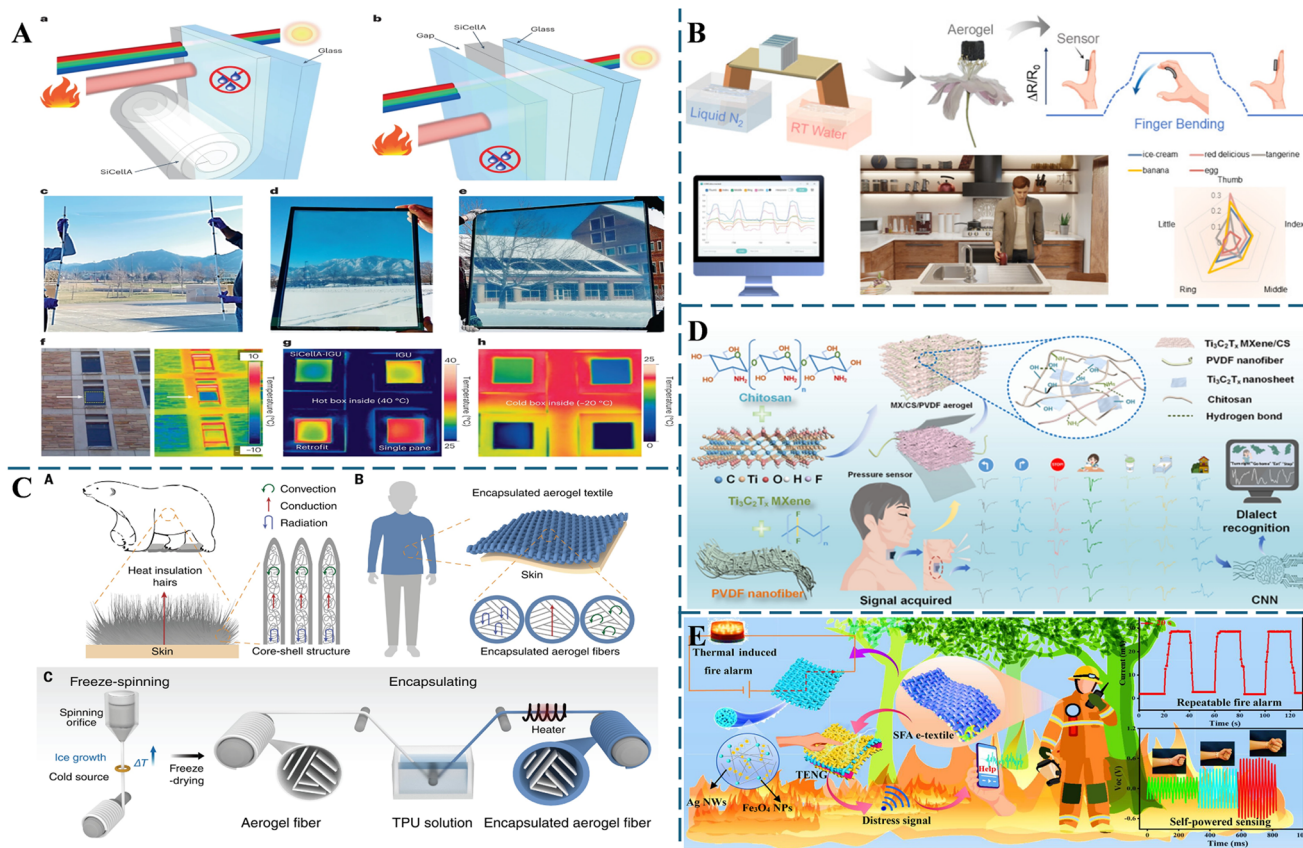

Fig. 10 (A) Schematic representation of silanized cellulose aerogels for enhancing the energy efficiency of glazing windows in buildings. Reproduced from ref. 150. (C) Design, fabrication, and thermal insulation properties of encapsulated aerogel fiber. Reproduced from ref. 153. (D) MXene composite aerogel-based pressure sensors for speech recognition and deep learning. Reproduced from ref. 144. (E) Schematic representation of the applications of self-powered e-textile fire alarms in energy harvesting, smart firefighting, location sharing, and real-time fire warning. Reproduced with permission from ref. 142. Copyright 2022, American Chemical Society.

To overcome this challenge, Wu *et al.*¹⁵³ encapsulated aerogel fiber in a stretchable layer to create a core-shell aerogel structure. The resulting fiber was stretchable up to 1000% strain despite having an internal porosity of over 90%. The fiber was mechanically robust and retained thermal insulation properties even after 10 000 stretching cycles (Fig. 10C). Speech recognition can help overcome language barriers and assist human-computer interactions. Xiao *et al.*¹⁴⁴ reported a MXene/chitosan/polyvinylidene difluoride aerogel-based pressure sensor with a rapid response and low hysteresis for speech recognition through throat muscle vibrations. The device was able to detect six dialects and seven different words in a significant step towards human-computer interaction and speech recognition (Fig. 10D). A conductive aerogel comprising magnetite nanoparticles, calcium alginate, and silver nanowires was reported for the fabrication of a self-powered fire alarm e-textile. The e-textile was able to sense a wide range of temperatures, ranging from 100 to 400 °C, and send accurate geo-location to a nearby device, aiding in rescuing trapped firefighters (Fig. 10E). Wearable electronic devices convert physical signals such as strain, pressure, temperature, and acoustic signals into

electrical signals based on capacitive, resistive, piezoelectric, or triboelectric principles.^{154,155} Liu *et al.*³² described a cellulose aerogel-based e-skin for personal healthcare applications. The e-skin realized a multifunctional wearable device for hyperthermia therapy, intelligent electronic masks, and dual-modal sensing.

7. Environmental monitoring

An interesting recent trend in aerogel technology is its application in environmental monitoring.^{156–159} Aerogel-based sensors have been reported for detecting pesticides,^{160–162} volatile organic compounds (VOCs),^{163,164} heavy metals,¹⁶⁵ bisphenols,^{61,62,166} glyphosate,¹⁶⁰ and pathogens in air and water. The porous structure and high surface area of aerogels are ideal for the adsorption and detection of trace amounts of pollutants and pathogens, resulting in sensitive environmental sensors. Aerogel-based sensors are also reported for detecting toxic gases such as nitrogen oxides,^{167–169} sulfur oxides,¹⁷⁰ carbon dioxide,¹⁷¹ formaldehyde,¹⁷² and ammonia.¹⁷³ The working principle of these sensors involves trapping molecules inside the porous

network of aerogels, leading to a measurable output signal such as a change in color, fluorescence, or conductivity. Zhang *et al.*¹⁶⁰ reported a photoelectrochemical phenylethynylcopper/N-doped graphene aerogel incorporated with magnetite nanoparticles as a nanozyme for the detection of glyphosate (Fig. 11A). This research combines analytical chemistry, environmental sensing, nanomaterials, and agricultural safety monitoring. The versatile hybrid sensing platform combines biocatalysis with the durability of nanomaterials, effectively addressing enzyme instability in environmental sensors. The 3D aerogel composite enhanced

the transfer of the photogenerated electrons, providing high signal output and sensitivity. Furthermore, the peroxidase mimic, instead of the natural peroxidase enzyme, improved the stability of the sensor. The sensor reportedly provided a linear detection range for glyphosate detection from 5×10^{-10} to 1×10^{-4} M.

In another study, melamine-doped rGO/MXene aerogel was employed as an electrode material for the electrochemical detection of heavy metal ions Zn^{2+} , Cd^{2+} , and Pb^{2+} .¹⁶⁵ In this case, the composite material significantly enhanced the conductivity of the electrode, while the

melamine-doped MXene served as recognition sites for the metal ions (Fig. 11B). A novel environmental remediation through toxic dye removal was reported by Ali *et al.*¹⁷⁴ In this report, graphene aerogels embedded with gold nanoparticles were synthesized using an *in situ* reduction method. The aerogel composite successfully removed methylene blue from an aqueous solution up to an extent of 90% (Fig. 11C). Graphene aerogel with embedded ZnO nanoparticles was reported for the detection of NO₂ gas at room temperature.¹⁶⁷ In this research, an eco-friendly synthesis approach was adopted, with a zinc-carbon battery recovering the ZnO nanoparticles (Fig. 11D). The macroporous structure of the composite contributes to a higher response rate. The NO₂-sensing properties were reportedly attributed to the porous nature, high conductivity, and the interaction between p-type graphene and n-type ZnO. Zheng *et al.*¹⁷² reported an aerogel-based fluorescent sensor for detecting formaldehyde gas. In this report, a fluorescent probe sensitive to formaldehyde gas was synthesized and covalently attached to the silica aerogel (Fig. 11E). The aerogel exhibited a detection limit of 110 ppm for formaldehyde gas. Sensitive identification of volatile organic compounds (VOCs) at the ppm level is crucial for environmental safety. Liu *et al.* reported the sensitive multiplexed detection of VOCs on a plasmonic aerogel (graphene/AuNPs@ZIF-8) with tunable pores.¹⁷⁵ In this research, the macro- and mesopores of graphene aerogel, along with the micropores of ZIF-8 metal-organic

frameworks, enhanced the concentration of volatile organic compounds. The sensor identified multiple VOCs, including toluene, benzaldehyde, nitrobenzene, and benzyl alcohol, with high sensitivity (Fig. 11F). Ratiometric sensors are preferred for sensing applications due to their highly reliable signal output. Li *et al.*¹⁶² reported an intriguing electrochemical ratiometric sensor for the insecticide imidacloprid using a lotus root powder-derived biomass aerogel (Fig. 11G). In this work, the authors synthesized carbon nanotubes and UiO-66-NH₂-doped lotus root powder. The aerogel was immobilized with anthraquinone to produce one of the ratiometric signals.

8. Aerogel-based optical sensors

The colorimetric sensing applications of aerogels are significantly influenced by their high surface area, porous structure, chemical tunability, structural tunability, stability, and, in some cases, optical transparency. In most aerogel-based colorimetric sensors, the optical probes are immobilized within the aerogel pores. The large surface area and tunable properties enhance the optical signals, leading to improved detection. In some instances, the aerogel material itself catalyzes the colorimetric reaction. For instance, Yan *et al.*¹⁷⁶ reported a Pt-Bi aerogel colorimetric sensor for the discrimination of antioxidants. Here, antioxidants inhibit the intrinsic peroxidase-like activity of

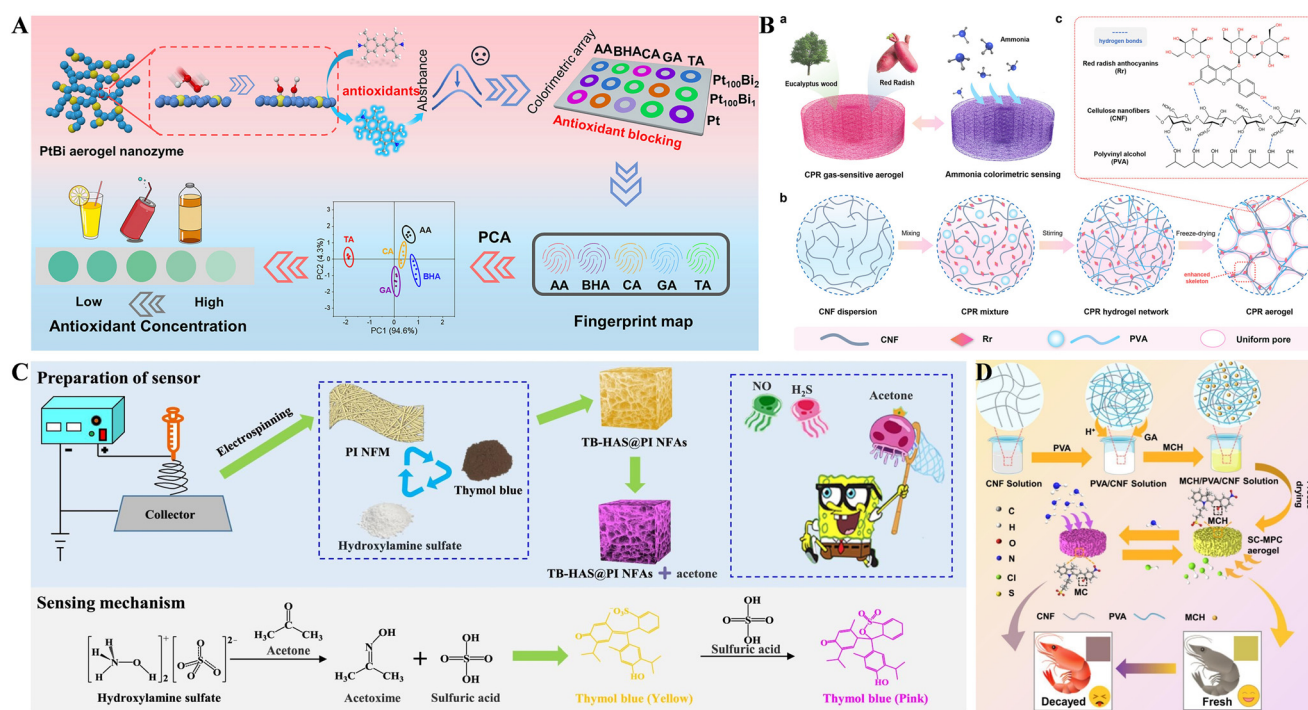

Fig. 12 (A) Schematic representation of the Pt-Bi aerogel-based colorimetric sensor array for the discrimination of antioxidants. Reproduced with permission from ref. 176. Copyright 2025, Elsevier. (B) Synthesis of poly(vinyl alcohol) and nanocellulose-based bio-aerogel for the colorimetric determination of ammonia. Reproduced with permission from ref. 177. Copyright 2025, Elsevier.

the Pt–Bi aerogel and prevent the oxidation of tetramethylbenzidine (Fig. 12A). Depending on the inhibitory effect of antioxidants, the color intensity varies, paving the way for the discrimination of antioxidants. Most nanozyme-based sensors depend on activation mechanisms, such as catalytic enhancement. This article presents an inhibition effect-based sensing model, where antioxidants suppress the catalytic activity of Pt–Bi aerogel nanozymes. The inhibition effect changes the colorimetric response, enabling quantitative and selective detection. This shift in detection strategy broadens the applications of nanozymes and improves the ability to distinguish similar analytes, like structurally related antioxidants.

Pan *et al.*¹⁷⁷ reported an environmentally friendly biobased aerogel for the colorimetric detection of ammonia. In this work, poly(vinyl alcohol) and pH-

responsive radish anthocyanins were introduced into cellulose nanofibers to construct the colorimetric aerogel. The anthocyanins changed the color of the aerogel upon exposure to ammonia, and the aerogel successfully detected ammonia in the concentration range of 10–100 ppm (Fig. 12B). Cao *et al.*¹⁷⁸ demonstrated a colorimetric sensor for breath acetone based on polyimide nanofiber aerogels incorporated with hydroxylamine sulfate and thymol blue. The sensor principle involved the conversion of hydroxylamine sulfate to acetoxime and sulfuric acid in the presence of acetone. The sulfuric acid then reacted with thymol blue to produce pink-colored thymol blue (Fig. 12C). Liu *et al.*¹⁷³ reported a cost-effective ammonia-sensitive aerogel based on sulfonic acid-functionalized spiropyran (Fig. 12D). The sensor operates on a straightforward mechanism of ammonia-mediated proton

framework for immobilizing a wide variety of biorecognition elements. Their hierarchical porosity significantly aids in the entrapment or covalent attachment of enzymes, antibodies, DNA probes, and aptamers, conserving their native activity and ensuring high sensitivity at low detection limits. For example, aerogels modified with enzymes have displayed remarkable catalytic performance and signal responsiveness in glucose sensors, while carbon aerogel-based immunosensors excel in detecting viral and bacterial antigens. Furthermore, molecular imprinting within aerogel matrices is emerging as a popular technique for creating artificial recognition sites for small biomolecules, offering an alternative to conventional bio-receptors.

Aerogels possess properties that enable advanced sensing capabilities, surpassing the limitations of conventional sensing materials. Conventional sensing materials generally exhibit lower surface-to-volume ratios, slower analyte diffusion, and reduced flexibility, which limits their suitability for applications demanding high sensitivity, rapid response, or integration into portable and wearable devices. In contrast, the extensive surface area and porous structure of aerogels provide numerous active sites for analyte adsorption, supporting detection at ultralow concentrations. This sensitivity often eliminates the need for signal amplification that traditional sensors require. The interconnected nanopores in aerogels facilitate efficient analyte diffusion, resulting in response and recovery times ranging from seconds to minutes. These rapid dynamics enable real-time sensing in applications such as wearable health monitoring, where conventional sensors may fail to detect transient events. Chemical modification of aerogels allows the incorporation of specific binding sites, thereby enhancing selectivity for target analytes and reducing interference. Additionally, aerogels exhibit elasticity and compressibility, enabling them to withstand significant deformation and supporting the development of piezoresistive sensors capable of detecting strains or pressures. These characteristics facilitate the creation of wearable technologies, including motion trackers that monitor wrist pulses, vocal-cord vibrations, or facial expressions in real time. Superhydrophobic aerogel variants maintain stable performance in humid or perspiring conditions, expanding their applicability in outdoor and biomedical environments. The low density of aerogels enables the fabrication of ultralight sensors suitable for portable applications, whereas bulky traditional setups are often impractical. Furthermore, durability, mechanical stability, and tunable hydrophobicity ensure reliable sensing in extreme environments, including high humidity and wide temperature ranges. These attributes enable aerogels to outperform conventional materials that may degrade or lose accuracy under such conditions.

Despite these advancements, several substantial limitations and technical challenges remain that must be overcome to fully harness the potential of aerogel-based biosensors. Traditional aerogels, particularly those made

from silica, often have mechanical fragility, restricting their application in dynamic or flexible environments. Moreover, their sensitivity to external factors, such as high humidity or extreme temperatures, can degrade sensor performance over time. Batch-to-batch variability and complexities in sensor fabrication further hinder scalability and reproducibility, posing significant barriers to commercial viability. Additionally, biosensing platforms confront fundamental issues related to long-term sensor operation due to biofouling. Aerogels themselves can act as antifouling coatings for biosensors. Their high porosity and customizable surface properties enable selective analyte access while inhibiting the adhesion of non-specific biomolecules or microbes. To enhance this capability, surface functionalization with hydrophilic or zwitterionic groups, along with the use of cellulose and alginate-based biopolymer aerogels, can produce antifouling coatings that maintain sensor functionality over time. This characteristic is particularly advantageous for wearable and implantable biosensors, where biofouling poses a continuous challenge. Another promising yet underexplored area is the integration of aerogels with microfluidic systems, which are increasingly essential in the development of miniaturized, point-of-care biosensing platforms. Thanks to their porous structure and surface functionalization options, aerogels can serve effectively as both support matrices and reaction chambers in microfluidic settings. Notably, when aerogels are combined with lab-on-a-chip devices, they facilitate localized biomolecule detection, efficient fluid management, and improved analyte capture through enhanced surface contact. Nevertheless, ensuring that aerogel production aligns with microfluidic device assembly techniques like photolithography or soft lithography remains a challenge. Thus, future research should aim at developing flexible aerogel composites that are both mechanically robust and suitable for microscale fabrication processes. Looking ahead, certain promising research avenues merit attention, particularly the development of hybrid aerogels comprising organic and inorganic materials or nanomaterials such as metal nanoparticles, carbon nanotubes, or quantum dots, which could address existing material limitations and enhance optical, electrical, and catalytic properties. These hybrid systems may significantly boost sensor performance, particularly in multiplexed or multi-analyte detection formats. Equally significant is the potential for smart aerogels that respond to stimuli like pH, temperature, light, or magnetic fields, paving the way for dynamic biosensors capable of real-time adaptation to biological changes.

Alongside these developments, the emergence of wearable and implantable aerogel-based biosensors is anticipated, particularly those utilizing flexible aerogel films or coatings. These innovations could transform personalized healthcare by enabling continuous monitoring of physiological factors, such as glucose levels, electrolyte balance, and infection indicators in sweat, blood, or interstitial fluids. Combined with advancements in materials science, the integration of
