Multiphase photochemistry in flow mode *via* an integrated continuous stirred tank reactor (CSTR) approach†

Antonella Ilenia Alfano, *^a Megan Smyth, ^b Scott Wharry, ^b
Thomas S. Moody, ^{bc} Manuel Nuño, ^d Chris Butters^d and Marcus Baumann *^a

A new photochemical CSTR system capable of handling solids in scaled continuous processes is presented. High-power UV-LEDs are integrated in these CSTRs containing an insoluble base that aids in generating pyrazolines *via* cycloaddition between alkenes and *in situ* generated diazo species. Contrary to reported batch methods product degradation *via* ring contraction is suppressed whilst generating gram quantities of spirocyclic pyrazolines.

Photochemical reactions continue to be emerging transformations for the effective generation of target molecules that are difficult to access *via* ground state chemistry. The last two decades alone have witnessed numerous reports from chemists in academic and industrial labs outlining new and highly selective strategies employing both visible light¹ and UV irradiation.² Whilst small scale reactions are easily accommodated in batch-based systems, the use of continuous flow approaches in combination with reaction automation is the method of choice for scale-up and library synthesis.³ Flow processing additionally offers advantages in relation to better heat transfer, more uniform irradiation, and unique spatiotemporal control, which altogether allow better reaction performance independent of reaction scale.⁴ Moreover, continuous flow-based photochemistry is suitable for the safe and effective use of gases as reaction partners. This allows for safe process intensification by using pressurised gaseous hydrocarbons in tetra-*n*-butylammonium decatungstate (TBADT)-catalysed HAT reactions,⁵ as well as scaled photo-oxidation reactions using air or oxygen gas.⁶ Whilst these examples showcase the advantageous use of gaseous reaction partners for cost-effective photochemical transformations, the use of solids in photoreactions remains a major challenge that impedes

on the development of equally attractive processes. The heterogeneous nature of such photochemical reactions thereby hinders light absorption and reproducibility for batch reactions, whereas continuous flow approaches will be challenging due to reactor fouling arising from blockages of narrow diameter channels.⁷ To date only a small number of bespoke solutions have been reported that accommodate solids in continuous photo-flow reactors. These include the HANU reactor which is an oscillatory flow reactor with static mixing elements capable of processing slurries. In a recent application, insoluble sodium carbonate was processed in a photo-catalysed reductive cross coupling reaction using the HANU reactor.⁸ An analogous heterogeneous photo-catalysed reaction was reported using a series of small CSTRs in combination with sodium carbonate that was introduced *via* a dedicated feeding pump.⁹ In addition, the use of ultrasonication has been demonstrated as part of a photo-catalysed triphasic oxidation reaction using benzylic alcohols, oxygen gas and insoluble titanium dioxide.¹⁰ A final concept study reports the use of a rotor-stator spinning disc reactor for the photochemical degradation of methylene blue using oxygen in the presence of titanium dioxide.¹¹

As part of our endeavours to access underexplored scaffolds with potential applications in medicinal chemistry we recently embarked on a study towards spirocyclic pyrazolines exploiting flow processing. Crucially these entities can be accessed *via* a dipolar cycloaddition reaction between electron-deficient alkenes and diazo species. The latter arise photochemically from *N*-tosylhydrazones in the presence of inorganic bases as reported recently by George and König.¹² However, a major limitation of this approach is the instability of the cycloadducts under the reaction conditions as they readily undergo ring contraction upon loss of nitrogen gas forming cyclopropanes instead (Scheme 1).

Whilst we surmised that superior spatiotemporal control provided by continuous flow processing would negate the fragmentation process, a remaining challenge concerned the necessary use of insoluble inorganic bases such as caesium

Scheme 1 Photochemical batch route to cyclopropanes *via* labile spirocyclic pyrazoline intermediates.

carbonate. To overcome this issue, we turned our attention to a newly developed photochemical CSTR module that is compatible with standardised commercial flow reactors such as the Vapourtec E-Series and R-Series flow systems. These CSTRs are made of glass (volume 50 mL) and integrate adjustable magnetic stirring, temperature control *via* compressed air cooling as well as an exchangeable high-intensity LED panel that can accommodate different wavelengths (*i.e.*, 365 nm *vs.* 420 nm, up to 70 W). As shown in Fig. 1, these photo-CSTRs can be used as single reactors or as part of a cascade whereby the liquid delivery is achieved *via* the pumps of the Vapourtec system (*i.e.*, piston or peristaltic pumps).

To validate the photo-CSTR module for multiphase transformations, we targeted the synthesis of Δ^1 -pyrazoline and Δ^2 -pyrazoline systems from bench stable *N*-tosylhydrazones and electron-deficient alkenes. Specifically, methyl methacrylate (**2a**) and *N'*-cyclopentylidene-4-methylbenzene-sulfonylhydrazide (**1a**) were used as reaction partners to generate methyl 3-methyl-1,2-diazaspiro[4.4]non-1-ene-3-carboxylate (**3a**). Initially, the mixture of reactants was pumped into the CSTR module in a semi batch fashion (*i.e.*, without simultaneous removal of the reaction mixture) to evaluate both reactivity and product stability. As summarised in Table 1, the exploration of key parameters quickly allowed the identification of the optimum residence time, flow rate, concentration, stirring rate and light intensity (*i.e.*, wattage). The best conditions were found when using 1.5 equiv. *N*-tosylhydrazone, 1.5 equiv. of Cs_2CO_3 , a substrate concentration of 0.1 M in DCM, light of 365 nm (36.7 W input power) and a residence time of 20 min (Table 1, entry 1), affording 95% yield of product **3a** under steady state conditions. When the substrate concentration was increased to 0.2 M employing

Table 1 Optimisation of reaction conditions towards **3a**

Entry	Deviations from above conditions	Yield ^a % 3a
1	None	95
2	0.2 M, 22 W	47
3	0.05 M	58
4	15 min	59
5	29 W	75
6	44 W	80
7	300 rpm	75
8	Dark	0

Reaction conditions: *N*-tosylhydrazone **1a** (3 mmol), methyl methacrylate **2a** (2 mmol), Cs_2CO_3 (3 mmol), DCM 0.1 M (20 mL), CSTR ($\lambda = 365$ nm, 36.7 W, 500 rpm), 35 °C, 20 min. ^a Yields of **3a** are calculated by ¹H NMR using trichloroethylene as internal standard.

22 W of input power, a drop in the yield was noticed (Table 1, entry 2). A lower concentration of 0.05 M or a shorter residence time of 15 min, did not improve the results as incomplete substrate conversion was observed (Table 1, entries 3 and 4). The yield decreased under both lower input power due to incomplete conversion (Table 1, entry 5) and higher input power due to the degradation into the anticipated spirocyclopropane product *via* nitrogen extrusion (Table 1, entry 6). Reducing the stirring rate to 300 rpm also gave a lower yield (Table 1, entry 7). Lastly, control experiments demonstrated that the light is essential for the observed reactivity (Table 1, entry 8).

Furthermore, a kinetic study was performed for the generation of compound **3a** revealing that the optimal residence time in the CSTR set-up is 20 min. At this point full conversion of the substrate is observed, whereas longer residence times show the onset of cyclopropane formation *via* nitrogen extrusion (Fig. 2).

When evaluating the scope of this process using ethyl acrylate as acceptor, modest results were initially obtained due to incomplete substrate conversion (Table 2, entry 1). Notably, this changed when performing the reaction at higher input power (50 W), whilst simultaneously increasing the residence time to 30 min and reducing the amounts of **1a** and Cs_2CO_3 to 1.2 (Table 2, entry 2). Whereas the input power minimally affected the reaction outcome (Table 2, entry 3), extended irradiation time resulted in partial product decomposition (Table 2, entry 4). Reducing the amount of **1a** resulted in incomplete substrate conversion and a product yield of 65% (Table 2, entry 5).

Next, the model reaction giving product **3a** was performed at slightly larger scales (2.6 and 6.6 mmol, Scheme 2), giving a yield of 95% at the smaller scale, whereas a lower yield of 77% together with *ca.* 20% remaining substrate was obtained when increasing the scale. This outcome likely points towards an inconsistent residence time distribution as the reaction scale is

Fig. 1 Image of photo-CSTR module with Vapourtec E-Series flow reactor.

Fig. 2 Reaction kinetics for the generation of **3a** (data based on $^1\text{H-NMR}$ spectroscopy).

Table 2 Optimisation of reaction conditions using ethyl acrylate

Entry	Deviations from above conditions	Yield ^a % 3b
1	None	40
2	50 W, 30 min, 1.2 equiv. of 1a and Cs_2CO_3	99
3	36.7 W, 30 min	90
4	36.7 W, 1 h	60
5	1.0 equiv. of 1a	65

Reaction conditions: *N*-tosylhydrazone **1a** (3 mmol), ethyl acrylate **2b** (2 mmol), Cs_2CO_3 (3 mmol), DCM 0.1 M (20 mL), CSTR ($\lambda = 365$ nm, 36.7 W, 500 rpm), 35 °C, 20 min. ^a Yields of **3b** are calculated by $^1\text{H NMR}$ using trichloroethylene as internal standard.

increased and suggests that a cascade of photo-CSTRs should be used when the process is further scaled (*vide infra*).

After the initial reaction optimisation, the resulting photochemical process was explored across a small set of *N*-tosylhydrazones whilst simultaneously varying the alkene component. As summarised in Scheme 2, this study successfully yielded a selection of interesting Δ^1 -pyrazolines and Δ^2 -pyrazolines and shows that acrylonitrile and *t*-butyl acrylate are suitable replacements as acceptor components giving the corresponding products in quantitative yields (**3c** and **3d**). When employing two different alkenes in combination with 4-methyl-*N'*-(1-methylpiperidin-4-ylidene) benzenesulfonylhydrazide as reaction partner the desired spirocyclic products **3e** and **3f** were again obtained in excellent yields without competing degradation. Additionally, it was found that slightly higher yields are obtained in the absence of an α -substituent adjacent to the electron-withdrawing group. The same trend was observed when using *N'*-cyclododecylidene-4-methylbenzene-sulfonylhydrazide as a larger cyclic fragment, furnishing the two spirocyclic products in 68% and 99% yield (**3g**, **3h**). Notably, no purification was required for Δ^2 -pyrazoline products (*i.e.*, **3b-d**, **3f** and **3h**), rendering this an attractive method to generate these scaffolds.

Scheme 2 Reaction scope towards spirocyclic Δ^1 -pyrazolines and Δ^2 -pyrazolines. Reaction conditions: *N*-tosylhydrazone **1a-c** (2.4 or 3 mmol), acrylate **2a-c** (2 mmol), Cs_2CO_3 (2.4 or 3 mmol), DCM 0.1 M (20 mL), CSTR ($\lambda = 365$ nm, 36.7 W or 50 W, 500 rpm), 35 °C, 20 or 30 min.

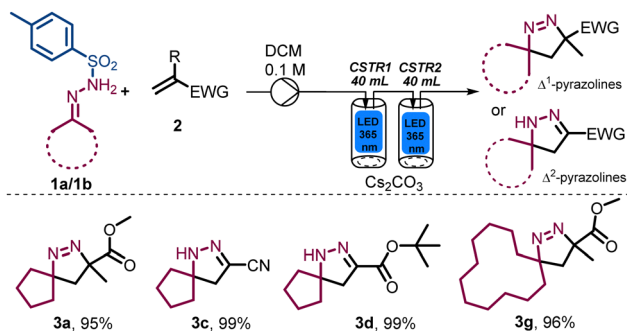

Having accomplished the selective synthesis of different Δ^1 -pyrazoline and Δ^2 -pyrazoline products in high yields, we targeted the preparation of selected examples at larger scale. As indicated for product **3a** (Scheme 2) a drop in conversion was noted during an initial scale-up attempt which was ascribed to a wider residence time distribution (RTD) in the CSTR.¹³ To overcome this problem, we opted to use two photo-CSTR modules in sequence, each being fitted with 365 nm LEDs. When CSTRs are connected in series, their RTD is sufficiently narrowed to become quasi plug flow. Building upon the established optimal conditions with this improved set-up, the scale-up of this transformation was successful (at 10 mmol and 15 mmol scale), furnishing yields greater than 95% for the Δ^1 - and Δ^2 pyrazolines targeted (Scheme 3).

To accommodate the increased heat generated from both photo-CSTRs that was anticipated to have a negative effect on the product stability, a stream of chilled air was used to regulate the CSTR temperature to *ca.* 35 °C. These adjustments were successful affording excellent yields for these products independent of the reaction scale. Overall, this approach shows reaction robustness and the importance of RTD in this application which reached a final throughput of 5 mmol h^{-1} .

A final aspect of our study concerned the integration of an extractive in-line work-up that would remove traces of inorganic materials and ensure isolation of clean pyrazoline products upon solvent evaporation only. To achieve this the solution exiting the second photo-CSTR was mixed with a stream of water before passing a Zaiput membrane separator.¹⁴ As summarised in Scheme 4, this approach worked well for the products tested and provided for a streamlined entry to pure products with minimal manual downstream processing (see ESI† for full details).

In conclusion, we have developed a robust continuous approach for the photochemical generation of Δ^1 -pyrazolines and Δ^2 -pyrazolines from readily available *N*-tosylhydrazones

Scheme 3 Improved reaction performance and scale-up using two sequential photo-CSTRs. Reaction conditions: *N*-tosylhydrazone **1a**, **1b** (15 or 12 mmol), acrylate **2a**, **2c** (10 mmol), Cs_2CO_3 (15 or 12 mmol), DCM 0.1 M (20 mL), CSTR ($\lambda = 365$ nm, 36.7 W or 50 W, 500 rpm), 35 °C, 20 or 30 min.

Scheme 4 Photo-CSTR cascade with integrated in-line work up using Zaiput membrane technology. Reaction conditions: *N*-tosylhydrazone **1a**, **1c** (15 or 12 mmol), acrylate **2a** (10 mmol), Cs_2CO_3 (15 or 12 mmol), DCM 0.1 M (100 mL), CSTR ($\lambda = 365$ nm, 36.7 W or 50 W, 500 rpm), 35 °C, 20 or 30 min. Typical run 2 h (t_{res} 116 min) incl. flushing CSTR with DCM.

and electron-deficient alkenes. Key to the success of this method is the use of a new photo-CSTR module containing solid Cs_2CO_3 as base which allows for the uniform irradiation of the resulting suspension *via* in-built UV-LEDs (365 nm). With reaction stirring, temperature control and light intensity being adjustable, this approach is highly effective in handling the heterogeneous reaction mixture without clogging as the solids are retained in the CSTR. Compared to prior batch-mode studies, our application harnesses superior spatiotemporal and thermal control which is crucial for realising selectivity in the generation of Δ^1 -pyrazoline and Δ^2 -pyrazoline products without competitive ring contraction to generate more stable cyclopropanes. Moreover, as prior batch studies were limited to small scale (*i.e.*, 0.2 mmol) we demonstrate reaction scalability towards gram quantities of products using a photo-CSTR cascade that ensures narrow residence time distribution and therefore consistently high substrate conversion. The integration of an extractive in-line work-up using a Zaiput membrane separator renders this approach an attractive strategy towards underexplored spirocyclic pyrazoline scaffolds.

We are grateful to Science Foundation Ireland (SFI) for providing funding for this research through a Future Frontiers Project grant (20/FFP-P/8712, M. B.). The School of Chemistry at

UCD is acknowledged for supporting our research program and providing access to all spectroscopic facilities. We thank Duncan Guthrie (Vapourtec) for the provision of the photo-CSTR units, and Andrea Adamo (Zaiput Flow Technologies) for fruitful discussions regarding the Zaiput membrane extractor.
