A novel ionic liquid functionalized graphene oxide supported gold nanoparticle composite film for sensitive electrochemical detection of dopamine

Jianbo Li, Yanhui Wang, Yuanling Sun, Chaofan Ding, Yanna Lin, Weiyan Sun and Chuannan Luo*

A simple and sensitive electrochemical sensor for detection of dopamine has been developed based on ionic liquid functionalized graphene oxide supported gold nanoparticles (GO-IL-AuNPs) coated onto a glassy carbon electrode. The prepared graphene oxide, ionic liquid functionalized graphene oxide and GO-IL-AuNPs were characterized in detail by scanning electron microscopy, X-ray diffraction and Fourier transform infrared spectroscopy. The electrochemical properties of the hybrid nanomaterials were evaluated through cyclic voltammetry and electrochemical impedance spectroscopy. Meanwhile, the activities of hybrid nanomaterials toward the oxidation of dopamine were analyzed *via* cyclic voltammetry and differential pulse voltammetry. The resulting sensor showed excellent electrocatalytic activity towards dopamine. Under the optimum conditions, differential pulse voltammetry was employed to detect ultra-trace amounts of dopamine, for which a wide linear range of 7 nM to 5 μM and a limit of detection 2.3 nM (S/N = 3) were obtained. The proposed sensor exhibited excellent accuracy and precision and the relative standard deviation (RSD) was less than 5%. The highly sensitive sensor was successfully used for accurate determination of the content of dopamine in practical samples.

1. Introduction

Dopamine (DA) is a catecholamine neurotransmitter secreted by the brain that plays a critical role in maintaining the functional activities of many organs, such as the heart, brain and kidney.[1–3] Dopamine can directly affect human emotions, learning and memory ability. Meanwhile, as a very important neurotransmitter, it mainly exists in the body fluid and brain cells. Research indicates that abnormal levels of dopamine are linked to some ailments, such as Alzheimer's disease, depression, Parkinson's disease, hyperactivity disorder and schizophrenia.[4–7] Hence, the rapid and accurate measurement of the content of DA is a significant research area in clinical practice. So far, many analytical approaches have been developed for detection of DA, including high performance liquid chromatography,[8] fluorescence,[9] chemiluminescence,[10] mass-spectrometry,[11] capillary-electrophoresis,[12,13] and surface plasmon resonance.[14] However, the above-mentioned analytical methods are costly and time consuming, require complicated pretreatment, consume large quantities of chemical agents and produce environmental pollution. Compared with the above methods, electrochemical techniques for detecting DA have attracted considerable attention because of the major advantage of the

lower cost of the electrochemical instrument combined with fast detection, simplicity, facile operation and impressive cost-effectiveness. With the development of novel functional materials, chemically modified electrodes are now widely used for the detection of dopamine in order to achieve lower detection limits and improve analytical sensitivity and selectivity.[15,16]

Graphene oxide (GO) as a single-atom-thick and two-dimensional carbon material has attracted remarkable interest in electrochemical analysis since it was first successfully manufactured in 2004.[17–19] Graphene oxide is widely used in the sensing field for its excellent properties, such as huge surface area, unique structures and good chemical stability. GO is a layered flexible material with a wealth of functional groups, such as hydroxyl (OH), epoxy (C–O–C), and carboxyl (COOH) groups, on both the edges and basal planes. It can be easily functionalized to form GO-based materials. Guo *et al.* reported a high performance dopamine electrochemical sensor based on graphene oxide and Ag hybrid matrix electrodeposition L-lysine films, which was used to sensitively determine DA in the presence of ascorbic acid.[20] Ghoreishi *et al.* fabricated a graphene oxide nano-sheet modified carbon paste electrode for the determination of dopamine in the presence of tyrosine.[21] Thirumalraj *et al.* report the preparation of highly stable fullerene C_{60} decorated graphene oxide nanocomposite and its sensitive electrochemical detection of dopamine in rat brain and pharmaceutical samples.[22] GO-based materials modified electrodes are used for detection of

Key Laboratory of Chemical Sensing & Analysis in Universities of Shandong (University of Jinan), School of Chemistry and Chemical Engineering, University of Jinan, Jinan 250022, China. E-mail: chm_yfl518@163.com; Tel: +86 531 89736065

DA because of three major reasons: biocompatibility, rapid electron transfer and low cost.

Ionic liquids (IL) are composed of large organic cations, such as pyridinium, phosphonium or imidazolium, and a relatively small anion, such Cl^-, Br^-, or larger complexes like tetrafluoroborate or hexafluorophosphate. Ionic liquids have some unique properties, such as high electric conductivity, low volatility and low toxicity. IL as a promising material have attracted great interest in the last few years. They have been widely used as electrode modifiers for constructed sensors, because of their viscosity, high conductivity and fairly wide electrochemical window.[23–24] The excellent electrochemical conductivity of ILs could lead to more sensitive electrochemical responses, especially for the detection of trace components. Furthermore, ILs can be uniformly dispersed in graphene oxide owing to their good solvation properties.

In recent years, GO-based materials grafted onto noble metal nanoparticles have attracted considerable interest owing to their flexible structure, excellent catalytic capabilities and excellent electron transport properties.[25] Recently, gold nanoparticles have been considered as an attractive candidate because of their huge specific surface area, excellent biocompatibility, good chemical stability and outstanding conductivity and catalytic properties. The unique two-dimensional crystal structure of GO acts as the substrate support for gold nanoparticles, which was attributed to the high electrocatalytic activities and extraordinary electronic transport properties. Meanwhile, composite materials prepared by gold nanoparticles dotted on graphene oxide as an enhanced sensing material have unparalleled electrochemical performance.

Herein, nanocomposites composed of gold nanoparticles anchored to ionic liquid functionalized graphene oxide were achieved by a simple one pot reaction. Ionic liquid as a linker attached gold nanoparticles and graphene oxide through electrostatic forces. Combining the advantageous features of gold nanoparticles and ionic liquid functionalized graphene oxide, the nanocomposites could incur synergy on electrochemical properties and thus improve the sensitivity of the nanomaterials. The prepared nanomaterials-modified glassy carbon electrode exhibited remarkable electrochemical catalytic activities towards dopamine. With a huge specific surface area and a large quantity of oxygen groups, GO shows good adsorption of dopamine. These oxidized areas on the GO plane break the long-range conjugated network and π-electron cloud, leading to a degradation of carrier mobility and conductivity. Ionic liquid functionalized graphene oxide could effectively prevent the agglomeration of graphene oxide, and the conductivity of the electrode could be enhanced and AuNPs have excellent load effects. The introduction of AuNPs brings not only electrochemical activity but also a certain biocompatibility. Meanwhile, AuNPs can effectively catalyze the electrochemical reaction of dopamine on the electrode surface. The electrochemical performance of the as-prepared sensor toward the oxidation of dopamine was explored in detail. The results indicated that the proposed sensor could achieve simple and efficient detection of dopamine.

2. Experimental

2.1. Reagents and apparatus

Dopamine, epinephrine, serotonin, ascorbic acid, uric acid, chloroauric acid and 1-butyl-3-methyl imidazole hydrobromide were purchased from Aladdin Industrial Corporation (Shanghai, China). Graphite powder, H_2SO_4, HNO_3, KCl, $KMnO_4$ and ethanol were purchased from Sinopharm Group Chemical Reagent Co. without further purification. The 0.1 M phosphate buffer solution (PBS) was prepared from Na_2HPO_4 and NaH_2PO_4. Chemicals used in the experiment were of analytical grade and all solutions were prepared with doubly distilled deionized water. Dopamine hydrochloride injection samples were purchased from the local hospital. The urine samples were collected from volunteers, and they were informed and agreed to follow the experiment.

All electrochemical measurements were performed on a CHI 660D electrochemistry workstation (Beijing Huake Putian Technology Co., Ltd. China). The classical three-electrode system was adopted. An Ag/AgCl (saturated KCl) electrode and a platinum electrode were used as the reference and counter electrodes, respectively. A bare or modified glassy carbon electrode (GCE) was used as the working electrode. Nanophase materials were characterized by scanning electron microscopy (S-2500, Hitachi High-tech International Trading Co., Ltd, Shanghai, China), X-ray diffraction (XRD, Focus D8 Bruker AXS Co. Ltd., Germany) and Fourier transform infrared spectroscopy (FTIR, Nicolet NEXUS-470, Thermo Nicolet, USA). Electrochemical impedance spectroscopy (EIS) was performed on a CHI 604D Electrochemical Workstation (Shanghai CH Instruments Inc., China). All the electrochemical experiments were carried out at room temperature.

2.2. Synthesis of GO-IL-AuNPs

The graphene oxide was synthesized from graphite power according to the modified Hummers' method.[26,27] The GO was dispersed in ultrapure water to get a stock solution of 1.0 mg mL^{-1}. 10 mg of 1-butyl-3-methyl imidazole hydrobromide was mixed with 10 mL of the GO dispersion. A GO-IL hybrid solution was obtained.

The gold nanoparticles were prepared using the method of sodium citrate reduction of chloroauric acid.[28] 3.65 mL of chloroauric acid solution (0.01 M) was diluted into 150 mL and heated to micro-boiling. Then, 3.0 mL of sodium citrate was quickly added whilst heating and stirring. When the solution turned wine red, heating was stopped but stirring was continued until the solution was cooled to room temperature. The gold nanoparticles were stored in a refrigerator at 4 °C. 10 mL of gold nanoparticles was added into 20 mL of GO-IL hybrid solution, and ultrasonic treatment for 30 min produced the GO-IL-AuNPs composite.

2.3. Preparation of the modified electrodes

Prior to the modification, the glassy carbon electrode (GCE) was polished with 0.3 and 0.05 μm alumina slurries sequentially. Subsequently, the electrode was washed thoroughly with
Scheme 1 Schematic illustration of the electrochemical sensors for the determination of DA.

Fig. 1 The SEM images of (a) GO, (b) GO-IL, (c) AuNPs, (d) GO-IL-AuNPs.

ultrapure water and dried at room temperature. 5 μL of the as-prepared GO-IL-AuNPs composite suspension was modified to the surface of the polished GCE and the GO-IL-AuNPs nanofilms modified GCE (GO-IL-AuNPs/GCE) was thus obtained. The schematic illustration is shown in Scheme 1. As a control, GO modified GCE (GO/GCE) and GO-IL modified GCE (GO-IL/GCE) were also prepared.

3. Results and discussion

3.1. Characterization of the nanocomposites

The surface topography of (a) GO, (b) GO-IL, (c) AuNPs and (d) GO-IL-AuNPs nanocomposites was investigated by SEM measurement, and the SEM images are shown in Fig. 1. It is clear from Fig. 1a that the prepared graphene oxide displayed a typical crumpled and wrinkled lamellar structure. Fig. 1b presents an SEM image of GO-IL, which indicates that the surfaces of the GO sheets were uniformly coated with IL. Fig. 1c shows the SEM image of AuNPs, which show a particle diameter in the range of 12–18 nm. The representative SEM image of GO-IL-AuNPs is also shown in Fig. 1d, clearly illustrating that the uniform particle size gold nanoparticles are evenly decorated on the surface of the GO-IL, which suggests that GO-IL-AuNPs have been successfully synthesized.

The XRD patterns of (a) GO, (b) GO-IL, (c) GO-IL-AuNPs are given in Fig. 2A. It is obvious that graphene oxide displays a strong spectral peak at 10.3° corresponding to the (0 0 2) diffraction crystalline plane.[29] The XRD patterns of GO-IL are shown in Fig. 2Ab, and many diffraction peaks between 20° and 30° were attributed to the ionic liquid crystal structure[30] and proven successful synthesis of GO-IL. The XRD pattern of the GO-IL-AuNPs composite shows the major diffraction peaks of 2θ at 38.4°, 44.2° and 65.3°, which corresponded to the (1 1 1), (2 0 0) and (2 2 0) planes of AuNPs and proved that AuNPs were successfully loaded on the surface of GO-IL.

To further investigate the formation of GO and GO-IL, FT-IR spectra were obtained. The FT-IR spectrum of GO is shown in Fig. 2Ba; the characteristic absorption bands at about 3400, 1720, 1640, 1400 and 1100 cm^{-1} correspond to the stretching vibrations of hydroxyl groups, carboxyl groups, alkene, carbon skeleton and epoxy, respectively.[31] The spectrums of GO-IL
exhibit typical 1-butyl-3-methyl imidazole hydrobromide absorption features of N–H stretching vibration (3120 cm^{-1}), symmetric methylene stretching vibrations (2870 cm^{-1} and 2960 cm^{-1}), C–N stretching vibration (1630 cm^{-1}), imidazole ring skeletal vibration (1570 cm^{-1}), imidazole ring deformation (1060 cm^{-1}), and C–H out-of plane bending vibration (835 cm^{-1}, 735 cm^{-1} and 620 cm^{-1}).[32,33] The results indicate that GO has been combined with the ionic liquid.

3.2. Electrochemical studies

Electrochemical impedance spectroscopy (EIS) is a powerful and effective method to monitor the interfacial properties of different modified electrodes. In the electrochemical imped-ance spectra, the semicircle part at high frequencies refers to the electron transfer controlled process and the linear part at low frequencies represents the diffusion controlled process. The semicircle diameter of the Nyquist plots is equal to the electron transfer resistance (R_{et}), which controls the electron transfer kinetics of the redox reaction at the electrode surface.[34,35] The electron transfer resistance can be directly calculated through the semicircle diameter. The electro-chemical impedance of the bare GCE, GO/GCE, GO-IL/GCE and GO-IL-AuNPs/GCE was determined in 0.2 mM $[Fe(CN)_6]^{3-/4-}$ solution containing 0.1 M KCl over the impedance frequency range from 1.0×10^5 to 0.1 Hz. The Nyquist spectra are shown in Fig. 3A. It was easy to get the R_{et} of the bare GCE, GO/GCE, GO-IL/GCE and GO-IL-AuNPs/GCE, which were about 278 Ω, 1032 Ω, 117 Ω and 37 Ω, respectively. At the same time, the R_{et} of these electrodes were in the following order: GCE > GO/GCE > GO-IL/GCE > GO-IL-AuNPs/GCE. This indicates that the resis-tance of electron transfer is effectively reduced owing to the introduction of IL and gold nanoparticles with excellent elec-tron transfer properties. The GO-IL-AuNPs/GCE has good electro-catalytic performance for oxidation of DA.

The electrochemical behaviors of DA at different modified electrodes were investigated using cyclic voltammetry. Fig. 3B shows the CVs of the bare (a), GO (b), GO-IL (c) and GO-IL-AuNPs (d) modified electrodes in 0.1 M PBS (pH 7.0)
Fig. 2 (A) The XRD patterns of (a) GO, (b) GO-IL and (c) GO-IL-AuNPs. (B) The FT-IR spectra of (a) GO and (b) GO-IL.

containing 1 μM DA at a scan rate of 100 mV s⁻¹. As can be seen from Fig. 3Ba, the bare GCE shows an obvious electrochemical oxidation peak for DA. Compared with the bare electrode, the DA electrochemical response signal intensity at the different modified electrodes was increased, which indicated that the modified materials have excellent electrical conductivity and electro-catalytic activity for DA oxidation. It is worth noting that a significant enhancement response signal was observed at the GO-IL-AuNPs/GCE (Fig. 3Bd), proving that the GO-IL-AuNPs nanocomposite has excellent electrical conductivity and electro-catalytic properties for oxidation of DA. Furthermore, the CVs responses of DA at the different electrodes were investigated in the presence of ascorbic acid. As shown in Fig. 3C, the CVs response of the bare GCE and GO modified GCE are only observed as one peak for the oxidation of AA and DA in PBS solution with 1 μM DA and 40 μM AA, indicating that the peak potential for AA and DA is indistinguishable. However, two well-defined oxidation peaks, corresponding to the oxidation of AA and DA, respectively, are clearly observed in the CV responses of the GO-IL and GO-IL-AuNPs modified GCEs, which provides the possibility of the detection of DA in the presence of ascorbic acid. The ionic liquid has a stronger electrical conductivity so

may have better adsorption capacity for dopamine. Furthermore, the gold nanoparticles have better catalytic performance for dopamine.

3.3. Optimization of the experimental conditions

3.3.1. Influence of the amount of GO-IL-AuNPs nanocomposite suspension. The effect of the loading amount of GO-IL-AuNPs on the electrode surface on the sensing properties was investigated. The relationship between the peak currents of DA and the amount of GO-IL-AuNPs on the GCE is shown in Fig. 4A. The response current value of 1 μM DA gradually increased with the increase of the amount of GO-IL-AuNPs (1 mg mL⁻¹) modified to the electrode surface from 3 to 6 μL. Nevertheless, a further increase in the volume of modification conversely caused a decrease in the response current of DA. Consequently, 6 μL of GO-IL-AuNPs suspension was thought to be the optimal amount for the modified electrode.

3.3.2. Effect of solution pH. The effect of pH on the electrochemical response of 1 μM DA was investigated over the pH range from 4.5 to 7.5 and the results are shown in Fig. 4B. It is obvious that the peak current of DA increases continuously with

Fig. 3 Electrochemical impedance spectroscopy recorded in 0.2 mM K₃[Fe(CN)₆] solution (A). Cyclic voltammograms showing the response of different modified electrodes to 1 μM DA (B); 1 μM DA and 40 μM AA (C) in 0.1 M PBS. (a) GCE, (b) GO/GCE, (c) GO-IL/GCE, and (d) GO-IL-AuNPs/GCE.
Fig. 4 (A) Effect of the volume of GO-IL-AuNPs. (B) Effect of pH value. (C) Effect of accumulation time. (D) CVs of GO-IL-AuNPs/GCE in 0.1 M PBS (pH 5.5) with 10 μM DA at different scan rates (0.02, 0.05, 0.08, 0.1, 0.12, 0.15, 0.18, and 0.2 V s^{-1}). Inset: the linear relationship between peak current and scan rate.

the increasing of the pH from 4.5 to 5.5, and then gradually decreases on further increasing of the pH. Therefore, pH of 5.5 was considered to be the optimal pH for the subsequent electrochemical experiments.

3.3.3. Effect of accumulation time. There is no doubt that the accumulation time will affect the sensitivity of the proposed sensor. The accumulation time can increase the amount of DA on the surface of the modified electrodes and thus improve the electrochemical response signal. Fig. 4C shows the relationship between the response current and the accumulation time. The response current gradually increased with the accumulation time increasing from 10 to 70 s. When the accumulation time exceeded 70 s, the peak current leveled off. Taking into account the sensitivity and efficiency of the sensor, 70 s was selected as the optimum accumulation time for the determination of DA.

3.3.4. Effect of scan rate. The effect of different scan rates on the electrochemical behavior of 10 μM DA at the GO-IL-AuNPs/GCE was investigated with cyclic voltammetry. The corresponding cyclic voltammograms are shown in Fig. 4D. It can be seen that the oxidation peak current increased gradually with the increase of scan rate. The linear relationship between the oxidation peak current and scan rate was obtained in the range of 0.02–0.2 V s^{-1} and the linear regression equation was I_p (μA) $= 7.93005 + 101.3351\nu$ (V·s^{-1}), $R = 0.9994$. It indicated that the oxidation process of DA at the GO-IL-AuNPs/GCE surface was

a typical adsorption controlled process rather than a diffusion controlled process.

3.4. Analytical characteristics

Under the optimal experimental conditions, the proposed sensor was employed for detecting various concentrations of DA

Fig. 5 Differential pulse voltammograms of different concentrations of DA at GO-IL-AuNPs/GCE (pH = 5.5). Inset: linear calibration curve in the range 7 nM to 5 μM DA.

Table 1 Comparison of the performances of some sensors for the detection of DA

	1.5	2.57	2.2	102
	2.0	3.00	2.5	99

in 0.1 M PBS by more sensitive differential pulse voltammetry. The electrochemical response of DA may follow the two proton transfer process through the ECE mechanism on the modified electrode. DA oxidation at the surface of the modified electrode was enhanced by diffusion and adsorption through graphene oxide and the ionic liquid, to make contact with the electrode surface easy and facilitate the electron transfer. The electro-catalytic performance of the GO-IL-AuNPs/GCE for DA is shown in Fig. 5. The inset of Fig. 5 displays the linear relationship between response current and the DA concentration in the range of 7 nM to 5 µM. The linearity regression equation was I_p (µA) $= 0.0111c$ (nM) $+ 2.4126$ ($R = 0.9994$). The detection limit of DA was calculated to be 2.3 nM (S/N $= 3$). The above results indicate that the reported GO-IL-AuNPs/GCE has excellent electro-catalytic ability for DA oxidation. As a comparison, the analysis performance of other dopamine sensors is listed in Table 1. It can be seen that the proposed sensor demonstrated better performance compared to other sensors.

To ensure the repeatability of the proposed sensor, repeated experiments were operated in PBS containing 1 µM DA with the same modified electrode. The results of ten measurements showed a relative standard deviation (RSD) of 2.8%. Additionally, the reproducibility of the sensor was estimated by using six sensors prepared in the same way for determination of the same DA solution. The relative standard deviation (RSD) was 3.1%. The storage stability of the proposed sensor was also evaluated. When the sensor was stored in the environment for two weeks, the response current was not significantly weakened and remained at 96.5% of its initial current response, and 92.2% of the initial current response remained after four weeks. These results indicated that the proposed sensor had good repeatability, reproducibility and stability.

In order to evaluate the potential of interference during DA detection, possible interfering compounds such as AA, glucose, uric acid (UA), epinephrine (EP) and serotonin (5-HT) were used. It was found that 40-fold concentrations of AA, uric acid, and epinephrine and 100-fold concentrations of glucose and serotonin (5-HT) had no obvious influence on the response current of 1 µM DA with deviations below ±5%. Besides, some 200-fold concentration of excess ions such as Mg^{2+}, Al^{3+}, Cl^-, SO_4^{2-} and NO_3^- had no influence on the DA response signal. These results demonstrate that GO-IL-AuNPs/GCE has good selectivity towards DA.

3.5. Detection of dopamine in real samples

In order to verify the reliability of the proposed sensor, the GO-IL-AuNPs/GCE was used for the analysis of DA in urine and dopamine hydrochloride injection samples by differential pulse cyclic voltammetry. The standard addition method was employed to analyze the content of DA in these actual samples. The results of the analysis are summarized in Table 2. As can be seen from the results in Table 2, the proposed sensor has good accuracy of detection with recoveries in the range from 98% to 102% and a relative standard deviation below 4%. The above sample analysis results indicate that the proposed sensor is very feasible and sensitive enough to detect trace dopamine in real samples. The sample was characterized by high performance liquid chromatography after 50 cycles. As a result, dopamine was not detected, which indicates that the DA had reacted completely after 50 cycling tests.

4. Conclusions

In this work, a novel platform of an electrochemical sensor based on 1-butyl-3-methylimidazolium cationic groups functionalized graphene oxide film loaded gold nanoparticles was constructed. The ionic liquid has good biocompatibility and strong electron transfer performance. The loading of gold nanoparticles significantly enhanced the catalytic performance of the complexes. The electrochemical properties were evaluated toward the electro-oxidation of dopamine. The interference experiments showed that some common interferents, such as uric acid, epinephrine, and ascorbic acid, caused no interference in the determination of dopamine. Moreover, the proposed sensor has good stability, excellent selectivity and good electrocatalytic activity. Under the optimal conditions, a stable linear relationship was observed between the response current and the concentration of DA in the range from 7 nM to 5 µM with a limit of detection 2.3 nM. The as-prepared sensor was employed to analyze real samples and achieved satisfactory results.
