The effects of Bi_2O_3 on the selective catalytic reduction of NO by propylene over Co_3O_4 nanoplates

Dezhong Yu, Da Xin Zhong, Dong Liu D*a and Ying Liangb

Bi₂O₃/Co₃O₄ catalysts prepared by the impregnation method were investigated for the selective catalytic reduction of NO by C_3H_6 (C_3H_6 -SCR) in the presence of O_2 . Their physicochemical properties were analyzed with SEM, XRD, H2-TPR, XPS, PL and IR measurements. It was found that the deposition of Bi₂O₃ on Co₃O₄ nanoplates enhanced the catalytic activity, especially at low reaction temperature. The SO_2 tolerance of Co_3O_4 in C_3H_6 -SCR activity was also improved with the addition of Bi_2O_3 . Among all catalysts tested, 10.0 wt% Bi₂O₃/Co₃O₄ achieved a 90% NO conversion at 200 °C with the total flow rate of 200 mL min⁻¹ (GHSV 30 000 h⁻¹). No loss in its C_3H_6 -SCR activity was observed at different temperatures after the addition of 100 ppm of SO₂ to the reaction mixture. These enhanced catalytic behaviors may be associated with the improved oxidizing characteristics of 10.0 wt% Bi₂O₃/Co₃O₂. XRD results showed that Bi₂O₃ entered the lattice of Co₃O₄, resulting in the formation of lattice distortion and structural defects. H₂-TPR results showed that the reduction of Co₃O₄ was promoted and the diffusion of oxygen was accelerated with the addition of Bi_2O_3 . XPS measurements implied that more Co^{3+} formed on the 10.0% Bi₂O₃/Co₃O₂ catalysts. The improved oxidizing characteristics of the catalyst with the addition of Bi_2O_3 due to the synergistic effect of the nanostructure hybrid, thus enhanced the C_3H_6 -SCR reaction and hindered the oxidization of SO₂. Therefore, the 10.0% Bi₂O₃/Co₃O₄ catalyst exhibited the highest NO conversion and strongest SO₂ tolerance ability.

1 Introduction

Lean burn engines, which are generally used in gasoline and diesel powered vehicles, are more fuel-efficient than the stoichiometric gasoline engines. They also effectively reduce unburned hydrocarbons, CO_2 and CO in exhausts. However, lean burn engines operate with a large excess of air, leading to a significant concentration of oxygen in the exhausts, where the noble-metal three-way catalysts cannot work well to reduce nitrogen oxides (NO_x) . A large amount of NO_x produced by lean burn engines leads to serious air pollution and public health problems.

In order to control NO_x emission under the lean burn conditions, selective catalytic reduction of NO by hydrocarbons (*e.g.* propylene) has been undertaken and reported in the literatures as one potential application (HC-SCR). Many classes of catalysts, including supported noble metals (*e.g.* Pt,^{4,5} Au^{6,7}), metal oxides (*e.g.* Ag₂O,^{8,9} CuO,^{10,11} SnO₂,¹²⁻¹⁴ CoO_x (ref. 15–18)) and zeolite types (ZSM-5,¹⁹ MCM-41 (ref. 20)) have been investigated. In general, the noble metals are active and stable even at lower temperature, but the formation of N₂O is undesirable by using

such precious metals, particularly, platinum-based catalysts. The zeolite-based catalysts were low thermal stability. Among metal oxides catalysts, cobalt oxides (*e.g.* Co₃O₄) are considered as one promising catalyst for HC-SCR due to its high catalytic activity.²¹ When combined with other oxides, such as CeO₂,¹⁶ ZrO₂,¹⁵ Al₂O₃,¹⁸ sulphated ZrO₂,²² the catalytic performances of the cobalt oxide catalyst could be improved as reported. These results implied that the chemical environment around cobalt oxide plays a crucial role in controlling the overall activity of cobalt containing catalysts in SCR reactions.

 $\rm Bi_2O_3$, a common oxide semiconductor, is widely used in the fields of chemical engineering and electronics such as NO detection and the oxidation or ammoxidation of propylene. $^{\rm 24,25}$ In the oxidation/ammoxidation of propene over bismuth/molybdate catalyst, bismuth was thought to involve the rate-determining hydrogen abstraction from propylene, $^{\rm 26}$ exhibiting its mild oxidizing characteristics. This property might be also beneficial for the partial oxidation of propylene in $\rm C_3H_6\textsc{-}SCR$ for NO reduction. Therefore, it is of considerable interest to explore the application of $\rm Bi_2O_3$ in the reduction of NO with propylene.

In the present study, Co_3O_4 nanoplates and Bi_2O_3/Co_3O_4 were prepared with the solvothermal and impregnation method respectively. Their catalytic performances in the NO reduction by C_3H_6 in the presence of O_2 were investigated. The catalysts

were characterized with X-ray diffraction (XRD), temperature programmed reduction with hydrogen (H_2 -TPR), and X-ray photoelectron spectra (XPS). The effects of Bi_2O_3 on the selective catalytic reduction of NO by propylene over Co_3O_4 nanoplates were expected to be elucidated.

2 Experimental

Paper

2.1 Preparation of Co₃O₄ and Bi₂O₃/Co₃O₄

The $\mathrm{Co_3O_4}$ support was synthesized via the solvent-thermal method, 50 mmol $\mathrm{CoCl_2}$ solution (200 mmol $\mathrm{L^{-1}}$, Sinopharm Chemical Reagent Co. China) and 25 mL of NaOH (2 mol $\mathrm{L^{-1}}$, Sinopharm Chemical Reagent Co. China) were added to a round-bottom flask, ultrasonicated for about 20 minutes to obtain a light brown uniform suspension. And then the suspension was transferred into a stainless steel autoclave with Teflon liner. The autoclave was sealed and maintained at 120 °C for 12 h. The obtained product was collected after washing with deionized water for several times, finally calcined at 500 °C for 5 h in air (S1).

The Bi₂O₃/Co₃O₄ catalysts with different Bi₂O₃ contents were synthesized by impregnation method as followed: 0.0155 g Bi(NO₃)₃·5H₂O and 20 mL 3% NH₃·H₂O were added into a round-bottom flask, ultrasonicated for about 20 minutes to obtain a white uniform suspension. After that, the Co₃O₄ support (S1) were added in the suspension, ultrasonicated for about 15 minutes to make it homogeneously distributed in the suspension. The suspension was then dried at 80 °C with continuous stirring for 1 h, further heated at 120 °C for 12 h followed by calcination at 500 °C in air for 4 h, yielding the 5.0 wt% Bi₂O₃/Co₃O₄ catalyst (S2). 10.0 wt% Bi₂O₃/Co₃O₄ (S3) and 15.0 wt% Bi₂O₃/Co₃O₄ (S4) were prepared with 0.0310 g and 0.0465 g Bi(NO₃)₃·5H₂O respectively. In addition, the physical mixture of 10% Bi₂O₃ nanoparticles and Co₃O₄ support was also prepared and labeled as S5. As references, classical catalysts 4% Ag/Al₂O₃ and 2% Pt/Al₂O₃ were prepared to compare the catalytic performance of the Bi₂O₃/Co₃O₄ catalysts.

2.2 Catalytic activity tests

 C_3H_6 -SCR over the catalysts was carried out at atmospheric pressure in a fixed-bed quartz reactor (diameter = 10 mm). 0.1 g catalyst was used in each run with a reaction mixture composed of 200 ppm NO, 200 ppm C_3H_6 , 100 ppm SO₂ (when needed) and 10 vol% O₂ in balance gas N₂. The total flow rate was 200 mL min⁻¹, corresponding to a GHSV 30 000 h⁻¹. Reaction temperature ranges from 100 to 500 °C. The concentration of NO was continuously measured by a NO analyzer (Thermo Environmental Instruments Inc., model 42c), which monitors NO, NO₂, and NO_x (NO_x represents NO + NO₂). The removal efficiency of NO was calculated as NO removal (%) = $(1 - C/C_0) \times 100\%$, where C and C_0 are concentrations of NO in the outlet and inlet, respectively.

2.3 Catalysts characterization

Scanning electron microscopy (SEM) images were taken on a Hitachi S4800 scanning electron microscope operating at 5.0 kV. X-ray powder diffraction (XRD) was carried out on

Brukeraxs D8 Discover (Cu K $\alpha = 1.5406$ Å). The scanning rate is 1° min⁻¹ in the 2θ range from 20 to 80 degree. The reducibility of Bi₂O₃/Co₃O₄ catalysts was estimated by temperature programmed reduction with hydrogen analysis (H2-TPR). The experiments were carried out with a Micromeritics 2910 apparatus using $H_2/Ar(3/97, v/v)$ gas with a total flow rate of 15 mL min $^{-1}$. In each run, 0.030 g of the catalyst was previously activated at 500 °C for 30 min under air, and then cooled to RT. TPR started with the introduction of the mixture of H₂ and Ar. The catalyst was heated from room temperature (RT) to 1000 °C (10 °C min⁻¹). H₂ consumption was continuously monitored with the thermal conductivity detector. X-ray photoelectron spectra (XPS) of the catalysts were measured in a VG Multilab 2000 spectrometer by using Al Kα (1486.6 eV) radiation as the X-ray source. Photoluminescence (PL) measurement was carried out on a Shimadzu RF-5301 PC fluorescence spectrophotometer. Raman spectra were recorded using a Horiba Jobin-Yvon Lab Ram HR800 Raman microspectrometer, with an excitation laser at 514 nm.

3 Results

3.1 Scanning electron microscope (SEM) observation and XRD analysis

Co₃O₄ nanoplates with different dimensions were observed on the support Co₃O₄ (S1), shown in Fig. 1(a). Fig. 1(b-d) presented Bi₂O₃/Co₃O₄ catalysts with different Bi₂O₃ loading amounts. It was shown that Bi₂O₃ nanoparticles with dimension *ca.* 20 nm were supported on Co₃O₄. And the crystal size of Bi₂O₃ slightly increased with increasing Bi₂O₃ loading amount from 5% to 15%.

Fig. 2(A) shows the XRD patterns of the synthesized Co₃O₄ and Bi₂O₃/Co₃O₄ catalysts. It can be seen that the Co₃O₄ support possessed the characteristic peaks of Co_3O_4 (JCPDS 73-1701, a =5.45 Å). Besides the characteristic peaks of Co₃O₄, the diffraction peaks due to Bi₂O₃ (JCPDS 22-515, a = 10.94 Å and c = 11.28Å) were also observed on Bi₂O₃/Co₃O₄ catalysts which became sharper with the increase of Bi₂O₃ loading amount. It was suggested that the crystal size of Bi₂O₃ was bigger on the catalyst with higher loading amount of Bi2O3, which was consistent with the SEM observations. Moreover, the diffraction peaks of Co₃O₄ over Bi₂O₃/Co₃O₄ catalysts behaved a slight shift towards lower degree in comparison with that of Co₃O₄, shown in Fig. 2(B). It indicated that the Bi3+ inserted the lattice of Co3O4 in the preparation process, and changed the lattice parameter of Co₃O₄ due to the different radius of Bi and Co atoms. At the same time, the characteristic peak of Co₃O₄ became weak obviously after the deposition of Bi2O3, which revealed the reduction of crystal size. It was implied that the insertion of Bi₂O₃ induced the structure defect of Co₃O₄ and suppressed the growth of crystal.

3.2 Temperature-programmed reduction by hydrogen (H_2 -TPR)

The H₂-TPR profiles of Co₃O₄, Bi₂O₃ and Bi₂O₃/Co₃O₄ catalysts were shown in Fig. 3. For the reduction of Bi₂O₃, a sharp peak

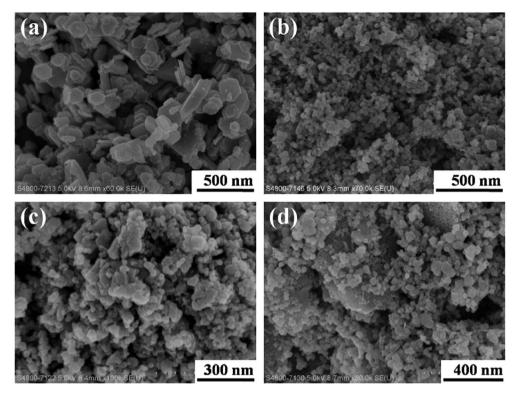

Fig. 1 SEM images of Co_3O_4 (a), 5.0% Bi_2O_3/Co_3O_4 (b), 10.0% Bi_2O_3/Co_3O_4 (c) and 15.0% Bi_2O_3/Co_3O_4 (d).

was observed at ca. 490 °C, implying the reduction of Bi3+ in a narrow temperature range. A broad reduction peak from 330 to 460 °C with a large shoulder at the lower reduction temperature (ca. 380 °C) appeared on Co₃O₄ support (S1). Many researchers reported that the reduction of Co₃O₄ was a two-step reduction process involving the intermediate reduction of CoO. 16,21,27 Two main clear reduction peaks respectively located around 186 $^{\circ}$ C and 310–480 $^{\circ}$ C were shown in the TPR spectra. The low temperature TPR peak was associated with the reduction of Co³⁺ to Co²⁺, and the peak at high temperature was the subsequent reduction of CoO to metallic cobalt. In the TPR spectrum of Co₃O₄ synthesized in the present work, there are no obvious two peaks probably due to an abroad particle size distribution as shown in SEM observation. The large shoulder at 376 °C (peak I) in Fig. 3 should be attributed to the reduction of Co³⁺ to Co²⁺, and main reduction peak (peak II) is ascribed to the reduction of CoO to metallic cobalt.

The reduction process of Bi₂O₃/Co₃O₄ catalysts (S2-S4) became complicated with the introduction of Bi2O3. The reduction peak at 487 °C became wider and shifted towards to the lower temperature, especially on the Bi₂O₃/Co₃O₄ catalyst with the highest Bi loading amount (S4). In addition, two new peaks around 342 °C (peak I) and 402 °C (peak II) respectively ascribed to the reduction of Co³⁺ to Co²⁺, Co²⁺ to metallic Co appeared on Bi₂O₃/Co₃O₄ catalysts (S2-S4).²⁸ Compared with the bulk Co₃O₄ (S1), both the reduction peak of Co³⁺ and that of Co²⁺ shifted to lower temperature after the deposition of Bi₂O₃, implying the promoted reduction of Co₃O₄. Moreover, the larger reduction peak I than peak II on S2-S4 samples indicated that

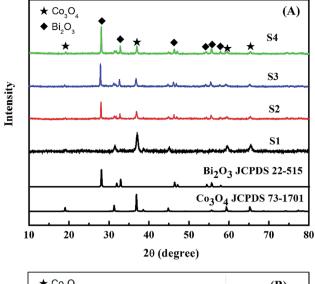

the ratio of Co³⁺/Co²⁺ was higher on S2-S4 samples than that on the Co₃O₄ (S1). It revealed that the deposition of Bi₂O₃ on Co₃O₄ affected the oxidized state of cobalt in the synthesized Co₃O₄, more Co3+ were present on the supported samples (S2-S4) than the pure Co₃O₄.

3.3 X-ray photoelectron spectroscopy (XPS)

XPS measurements were carried out on Co₃O₄ and 10.0% Bi₂O₃/ Co₃O₄ catalysts to examine the influence of Bi₂O₃ on the surface electronic state of Co₃O₄. The Co 2p and O 1s XPS profiles are shown in Fig. 4. In the Co 2p (Fig. 7(a)), the main peaks located at 779.6-781.3 eV and 794.8-796.5 eV are ascribed to Co 2p_{1/2} and Co 2p_{3/2} spin-orbital peaks, respectively.^{29,30} It was wellknown that the spin-orbit splitting value for Co³⁺ compounds is 15.0 eV, 15.1-15.3 eV for the mixed-valence Co₃O₄. Here, the spin-orbit splitting values of Co 2p for CO₃O₄ and 10.0% Bi₂O₃/ Co₃O₄ are the same, 15.2 eV, which is close to that of mixedvalence Co₃O₄. So the cobalt species on both S1 and S3 should be Co₃O₄, agreeable with the XRD and TPR results.

Based on the restriction that Co 2p_{3/2} binding energies of Co²⁺ and Co³⁺ components are 781.3 eV and 779.6 eV, respectively, the spin-orbit doublet splitting is 15.2 eV with a fixed ratio of 2/1 for the 2p_{3/2}-to-2p_{1/2} peak area,²⁹ the Co 2p spectra of S1 and S3 can be fitted to the Co²⁺ (peak II and IV) and Co³⁺ (peak I and III) components.30,31 The satellite peak of Co2+ and that of Co3+ in Co3O4 were also respectively observed at 787.0 eV and 791.0 eV.32,33 Fig. 4 shows that the peak areas of peak I and III increased with the addition of Bi₂O₃, implying that the surface Co³⁺ and the surface content ratio of Co³⁺/Co²⁺

Paper RSC Advances

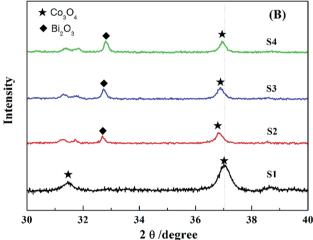

Fig. 2 XRD patterns of Co_3O_4 (S1), 5.0% Bi_2O_3/Co_3O_4 (S2), 10.0% Bi_2O_3/Co_3O_4 (S3) and 15.0% Bi_2O_3/Co_3O_4 (S4) in the wide (A) and narrow (B) ranges.

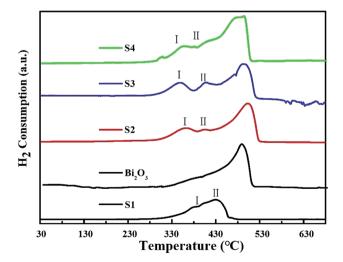

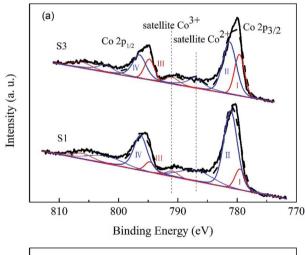

Fig. 3 H_2 -TPR profiles of pure Co_3O_4 (S1), Bi_2O_3 , 5.0% Bi_2O_3/Co_3O_4 (S2), 10.0% Bi_2O_3/Co_3O_4 (S3) and 15.0% Bi_2O_3/Co_3O_4 (S4).

increased with the addition of Bi_2O_3 . More Co^{3+} was present on 10.0% Bi_2O_3/Co_3O_4 (S3) than the bulk Co_3O_4 support (S1), as consistent with the TPR results.

The O 1s XPS spectra of Co_3O_4 and $\text{Bi}_2\text{O}_3/\text{Co}_3\text{O}_4$ catalysts are shown in Fig. 4(b). For the Co_3O_4 sample, there are two peaks (I and II). The peak I located at $\sim\!530.1$ eV is attributed to the surface lattice of Co_3O_4 , and the peak II at $\sim\!531.5$ eV is associated with OH^- groups. In the case of 10.0% $\text{Bi}_2\text{O}_3/\text{Co}_3\text{O}_4$, besides the peak I and II, one new peak at $\sim\!532.8$ eV appeared, which should be related to the contribution of the oxygen from Bi_2O_3 .

3.4 Photoluminescence (PL) and Raman spectra

PL emission spectra originating from the recombination of free charge carriers are useful to reveal the migration, transfer and separation of photogenerated charge carriers. Fig. 5 shows photoluminescence emission spectra of different catalysts at room temperature. All samples show one luminescence peak center at about 358 nm, which can be attributed to the radiative recombination of charge carriers. The pure Co_3O_4 has the strongest PL emission peak. This charge recombination process of Co_3O_4 can be greatly inhibited by the deposition of Bi_2O_3 on

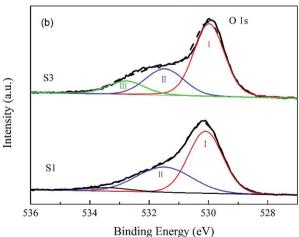

Fig. 4 $\,$ XPS study of Co $_3O_4$ (S1) and 10.0% Bi $_2O_3/Co_3O_4$ (S3): (a) Co 2p spectra, (b) O 1s spectra.

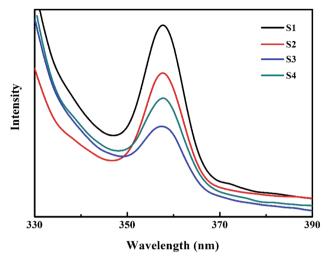

Fig. 5 Room-temperature PL spectra of Co_3O_4 (S1), 5.0% Bi_2O_3/Co_3O_4 (S2), 10.0% Bi_2O_3/Co_3O_4 (S3) and 15.0% Bi_2O_3/Co_3O_4 (S4).

 ${\rm Co_3O_4.~10.0\%~Bi_2O_3/Co_3O_4}$ (S3) has the lowest PL emission peak, which is associated with its structural imperfection. The structural imperfection originating from the insertion of the ${\rm Bi}^{3+}$ into the lattice of ${\rm Co_3O_4}$, as evidenced by XRD, increased the number of structural defects (*e.g.*, oxygen vacancies), which could capture the electrons or holes, thus resulting in low radiative PL emission.

Fig. 6 shows the Raman spectra of 10.0% Bi_2O_3/Co_3O_4 (S3), pure Co_3O_4 (S1) and Bi_2O_3 . For the pure Co_3O_4 , the Raman peak at 655 cm⁻¹ was corresponded to the symmetry of Co_3O_4 . S10.0% Bi_2O_3/Co_3O_4 gave the similar Raman spectra with Co_3O_4 , while the characteristic peaks of Bi_2O_3 could not be detected. Compared with Co_3O_4 , the Raman peaks on 10.0% Bi_2O_3/Co_3O_4 shifted to the lower frequencies with stronger intensities, which associated with the lattice distortion or residual stress of the spinel structure. The XRD results showed that part of Bi_2O_3 entered the lattice of Co_3O_4 over 10.0% Bi_2O_3/Co_3O_4 , leading to

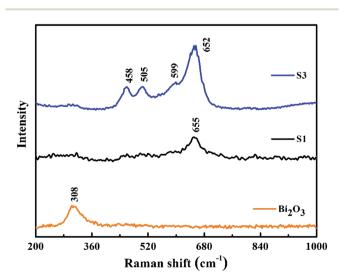

Fig. 6 Raman spectra of Co₃O₄ (S1) and 10.0% Bi₂O₃/Co₃O₄ (S3).

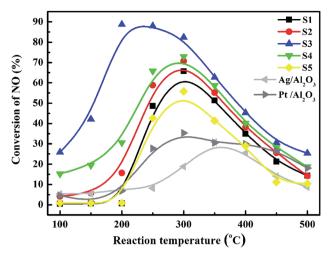

Fig. 7 NO conversions over the catalysts: S1: Co_3O_4 ; S2: 5.0% Bi_2O_3/Co_3O_4 ; S3: 10.0% Bi_2O_3/Co_3O_4 ; S4: 15.0% Bi_2O_3/Co_3O_4 ; S5: the physical mixture of Bi_2O_3 and Co_3O_4 .

the lattice distortion and lattice defect. The highly defective structure formed on 10.0% Bi₂O₃/Co₃O₄ could accelerate the adsorption and activation of O₂, which was suggested to be related to the better catalytic performance.

3.5 Catalytic performance

Fig. 7 depicted the NO conversions over the Bi₂O₃/Co₃O₄ catalysts with different Bi₂O₃ contents (S1-S4), the physical mixture of 10% Bi₂O₃ nanoparticles and Co₃O₄ support (S5), 4% Ag/ Al₂O₃ and 2% Pt/Al₂O₃ reference catalysts within the reaction temperature range of 100-500 °C. Co₃O₄ and Bi₂O₃/Co₃O₄ catalysts showed higher NO reduction activity than those of Ag/ Al₂O₃ and Pt/Al₂O₃, especially Bi₂O₃/Co₃O₄ catalysts. The conversion of NO over Co₃O₄ support (S1) firstly increased with reaction temperature, reached the maximum conversion (ca. 60%) at ca. 300 °C and then decreased at higher temperature. The NO conversion was further increased with the addition of Bi₂O₃ into Co₃O₄ with the activity order: Co₃O₄ (S1) < 5.0% Bi_2O_3/Co_3O_4 (S2) < 15.0% Bi_2O_3/Co_3O_4 (S4) < 10.0% Bi_2O_3/Co_3O_4 (S3). Among all catalysts tested, 10.0% Bi₂O₃/Co₃O₄ (S3) possessed the highest activity for NO conversion in the reaction temperature window, reaching ca. 90% NO conversion at 200 °C. NO conversion under the lower reaction temperature (100-250 °C) over S3 also reached the highest among the catalysts tested. In contrast, the mixture of 10% Bi₂O₃ nanoparticles and Co₃O₄ support (S5) showed lower activity than S1 and S3. It was indicated that the interaction between Bi₂O₃ and Co₃O₄ in S3 is not the simply physical mixture like S5. The chemical interaction between them took place in S3 and should contribute the admirable catalytic performance of S3 in the C₃H₆-SCR reaction.

 SO_2 usually exists in the diesel engine exhaust. So it is necessary to investigate the SO_2 tolerance of the catalyst in C_3H_6 -SCR. Fig. 8 exhibited the effects of 100 ppm SO_2 co-fed in the reaction gas on the NO conversions over the catalysts at the different reaction temperatures. NO conversion over the S3

Paper RSC Advances

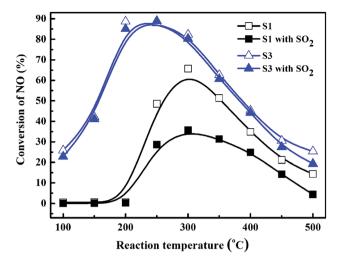

Fig. 8 SO_2 resistibilities of Co_3O_4 (S1) and 10.0% Bi_2O_3/Co_3O_4 (S3) with the reaction temperature.

(10% Bi_2O_3/Co_3O_4) catalyst clearly did not change in the wide reaction window. The steady-state NO conversion reached 90.3% on S3 at 250 °C in the presence and absence of SO_2 . In contrast, NO conversion decreased from 65.8% to 35.7% at 300 °C on the Co_3O_4 support (S1) when 100 ppm SO_2 was contained in the feed gas. NO conversions at other reaction temperatures also reduced in the presence of SO_2 . These results obviously suggested that 10% Bi_2O_3/Co_3O_4 exhibited good resistibility against SO_2 that coexists with NO and C_3H_6 in the reaction mixture.

Fig. 9 shows the SO_2 durability of 10% Bi_2O_3/Co_3O_4 catalyst with the reaction time at the optimum reaction temperature 200 °C in the C_3H_6 -SCR of NO. When NO conversion reached to the maximum (89.3%), 100 ppm SO_2 was added in the reaction system, NO conversion immediately decreased. It was probably due to the competitive adsorption of NO and SO_2 on the active site. 20 min later, NO conversion reduced to 63.6%. After that,

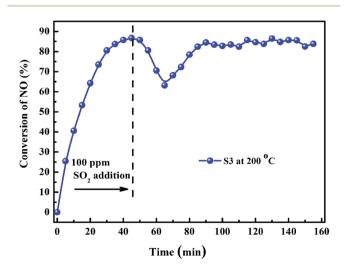

Fig. 9 NO conversion over 10.0% Bi $_2$ O $_3$ /Co $_3$ O $_4$ (S3) before and after the addition of SO $_2$ (reaction temperature: 200 °C).

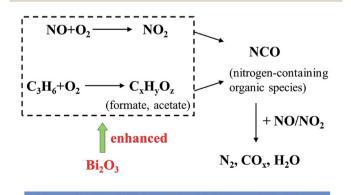

NO conversion recovered to 85.7%, and maintained at ca. 88% through the whole reaction period of 90 min. This result further illustrates the outstanding SO_2 resistibility of 10% Bi_2O_3/Co_3O_4 in the long time-reaction.

4 Discussions

In this study, the deposition of Bi_2O_3 with the proper loading amount on Co_3O_4 nanoplates enhanced NO conversion over Co_3O_4 , especially at low reaction temperature (<200 °C). 10.0% Bi_2O_3/Co_3O_4 catalyst also showed the strong resistibility against SO_2 in the feed gas. XRD results showed Bi_2O_3 could enter the lattice of Co_3O_4 , and promote the formation of the lattice distortion and structural defect as demonstrated by PL spectra and IR spectra. The H_2 -TPR and XPS results showed that more Co^{3+} appeared with the deposition of Bi_2O_3 . These changes were probably related to the promotive effects of Bi_2O_3 in the C_3H_6 -SCR reaction.

Scheme 1 illustrated the mechanistic investigations for the HC-SCR reactions in the previous literatures. 17,36,37 According to these findings, the reactants (C_3H_6 , NO and NO₂) are supposed to be first adsorbed on the active sites over the catalyst surface. Subsequently, the adsorbed nitrates formed via NO oxidation by O₂. C_3H_6 was also activated to form $C_xH_yO_z$ species such as formate, acetate and so on. As these $C_xH_yO_z$ species become available, nitrates subsequently reacted with them to yield nitrogen-containing organic species, such as NCO species. The final step would be the interaction of NOC intermediates with NO_x (NO, NO_x), decomposing into N₂, CO_x and H₂O as final products. This proposed reaction process reveals the crucial role of O₂ in the feed gas and the importance of oxidizing characteristics of the catalyst surface.

In our work, PL and IR results showed that more oxygen vacancies were produced on the $\mathrm{Co_3O_4}$ after the doping of $\mathrm{Bi_2O_3}$. The vacancy could accelerate the adsorption, activation and diffusion of oxygen, which was suggested to be available for the oxidation reactions involved in HC-SCR. The doped $\mathrm{Bi_2O_3}$ also increased the $\mathrm{Co^{3^+}}$ concentration on the surface. The richness of $\mathrm{Co^{3^+}}$ could promote the adsorption and activation of NO and (or) $\mathrm{C_3H_6}$. What is more is the mild oxidizing characteristics of

Bi₂O₃/Co₃O₄ showed high NO conversion and strong SO₂ tolerance.

Scheme 1 The promotive effects of $\rm Bi_2O_3$ on NO reduction by propene over $\rm Co_3O_4$ catalyst.

bismuth oxide in the selective oxidation and ammoxidation of propene to acrolein and acrylonitrile. It will accelerate the formation of $C_xH_yO_z$ species. In short, the addition of Bi_2O_3 into the Co_3O_4 in the present study probably influenced the oxidation process in the C_3H_6 -SCR reaction, favored the activation of C_3H_6 and NO, and then enhanced the following NCO intermediate formation and its decomposition with reaction with NO_x to N_2 .

About poisoning HC-SCR catalyst with SO2, the previous studies reported that the suppression effect of SO2 on the SCR catalyst could attributed to the formation of sulphate on the catalyst.38 The presence of surface SO42- groups blocked the formation of nitrate and decreased the amount of adsorbed nitrates. Thus it hindered the transformation of NOC species and decreased the catalytic activity. In our work, the presence of 100 ppm SO₂ in the feed gas decreased the NO conversion over Co₃O₄ catalyst, while the SO₂ tolerance of Bi₂O₃/Co₃O₄ was strong. 10% Bi₂O₃/Co₃O₄ showed the good stability when SO₂ was co-fed in the mixture gas during 90 min. This promotive role of Bi₂O₃ on the resistibility against SO₂ also could be explained by the oxidizing properties of 10% Bi₂O₃/Co₃O₄. The addition of Bi₂O₃ into Co₃O₄ promoted the partial oxidation of propene activation of C₃H₆. The activation of C₃H₆ over 10% Bi₂O₃/Co₃O₄ seems more competitive in the compassion with the oxidization of SO₂ to form surface sulfate. Subsequently, it is suggested that the addition of Bi₂O₃ into Co₃O₄ is one appropriate method for improving the SO₂ resistance of Co₃O₄.

5 Conclusions

The optimum $\mathrm{Bi_2O_3}$ loading on the $\mathrm{Co_3O_4}$ nanoplates for the $\mathrm{C_3H_6}\text{-SCR}$ of NO was about 10%, giving the best catalytic activity, especially at low reaction temperature, as well as the strongest $\mathrm{SO_2}$ tolerance. The decoration of moderate $\mathrm{Bi_2O_3}$ on $\mathrm{Co_3O_4}$ influenced the oxidation state of $\mathrm{Co_3O_4}$, facilitate the surface oxygen mobility and the partial oxidation of propene involved in the $\mathrm{C_3H_6}\text{-SCR}$ reaction. Therefore, the combination of $\mathrm{Co_3O_4}$ with $\mathrm{Bi_2O_3}$ is more active than $\mathrm{Co_3O_4}$. The addition of 100 ppm $\mathrm{SO_2}$ to the feed hardly affected the catalytic performance of 10% $\mathrm{Bi_2O_3/Co_3O_4}$.
