Two-dimensional transition metal dichalcogenide-based counter electrodes for dye-sensitized solar cells

Eric Singh, ^{abc} Ki Seok Kim, ^b Geun Young Yeom ^{*bc} and Hari Singh Nalwa ^{*d}

Dye-sensitized solar cells (DSSCs) are gaining considerable interest as alternatives to semiconductor-based thin film solar cells. The noble metal platinum (Pt) is conventionally used as a counter electrode (CE) material for fabricating DSSCs, since Pt is expensive and scarce, therefore, new materials have been explored to develop cost-effective Pt-free counter electrodes. Two-dimensional (2D) graphene-based counter electrodes have achieved the highest power conversion efficiency (PCE, η) of 13%, which has stimulated research activities in 2D layered transition metal dichalcogenides (TMDs) for developing Pt-free DSSCs. In this review, progress made on alternative counter electrodes for fabricating low-cost Pt-free DSSCs, based on earth-abundant 2D TMDs including MoS₂, WS₂, TiS₂, FeS₂, CoS₂, NiS₂, SnS₂, MoSe₂, NbSe₂, TaSe₂, NiSe₂, FeSe₂, CoSe₂, Bi₂Se₃ and their based composites, are discussed and summarized. Also, the considerable progress made on thin films of MoS₂ and MoS₂ based carbon, graphene, carbon nanotubes (CNTs), carbon nanofibers (CNFs), and poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PEDOT:PSS) composites as efficient counter electrodes (CEs) for DSSCs are discussed, in terms of their electrochemical and photovoltaic properties. At present, PCE values higher than that of standard Pt CE have been recorded for a number of TMD-based CEs, which include MoS₂ and MoSe₂/thin films deposited on Mo foil, MoS₂/CNTs, MoS₂/graphene, MoS₂/carbon, MoSe₂/PEDOT:PSS, NbSe₂, FeS₂, FeSe₂ nanosheets, TiS₂/graphene, and NiS₂/graphene hybrid systems in DSSCs, for the reduction of triiodide (I₃[−]) to iodide (I[−]). The highest PCE (η = 10.46%) *versus* Pt CE (η = 8.25%) at 1 Sun (100 mW cm^{−2}, AM 1.5G) was measured for DSSCs having a low cost and flexible CoSe₂/carbon-nanoclimbing wall counter electrode deposited on a nickel foam. Though TMD-based materials show great potential for solar cell devices, their long-term stability is equally important. The DSSCs with a TiS₂/graphene hybrid, and TiS₂/PEDOT:PSS composite CEs, showed stability up to 20 to 30 days, respectively, without any measurable degradation in the photovoltaic performance. The long-term stability of TMDs-based DSSCs under different environmental conditions is also described in view of their commercial applications.

1. Introduction: dye-sensitized solar cells (DSSCs)

Silicon has been traditionally used in fabricating solar cells. O'Regan and Grätzel¹ in 1991 demonstrated dye-sensitized solar cells (DSSC) as a low-cost approach and as an alternative to silicon solar cells. The concept of a DSSC system was hypothesized based on photosynthesis in nature. The first DSSC was

fabricated using nanocrystalline porous TiO₂ as optically transparent thin-film photoelectrodes and a ruthenium(II)-bipyridyl complex as a photosensitizer (dye), which generated a power conversion efficiency of 7.9% for the triiodide/iodide (I₃[−]/I[−]) redox couple. This inspired a new field of research based on DSSCs where a broad range of novel materials are now being explored for electrodes (photoanode and counter electrode (CE; cathode)), photosensitizers (dyes), and reduction-oxidation (redox) electrolytes for fabricating DSSC devices.

The commonly used components in dye-sensitized solar cells are a photoanode, a CE, a photosensitizing dye, and an electrolyte. These include tris(2,2'-bipyridyl)cobalt(II/III) [Co(bpy)₃] (Co²⁺/Co³⁺), triiodide/iodide (I₃[−]/I[−]) and 5,5'-dithiobis(1-methyltetrazole)/1-methyltetrazole-5-thiolate (T₂/T[−]) as redox couples, poly(3,4-ethylenedioxythiophene) (PEDOT), poly(styrenesulfonate) (PSS), poly(3-hexylthiophene) (P3HT), 2,2',7,7'-tetrakis(*N,N*-*p*-dimethoxy-phenylamino)-9,9'-spirobifluorene (spiro-OMETAD) as solid-state hole-transport

materials (HTM); *cis*-bis(isothiocyanato)bis(2,2'-bipyridyl-4,4'-dicarboxylato)ruthenium(II), (N3 dye), ditetrabutylammonium *cis*-bis(isothiocyanato)bis(2,2'-bipyridyl-4,4'-dicarboxylato)ruthenium(II), where tetrabutyl-ammonium cation: $[(C_4H_9)_4N^+]$ (N719 dye), and (tris(cyanato)-2,2',2''-terpyridyl-4,4',4''-tricarboxylate)ruthenium(II) (N749 or black dye) as photosensitizing dyes, are regularly used. The dye-sensitized mesoporous TiO_2 is used as a photoanode, while the Pt-coated fluorine-doped tin oxide (FTO) on a glass substrate is used as a CE, which facilitates the catalysis process. The counter electrode in a DSSC device acts as a catalyst. Pt counter electrodes yield the maximum electrocatalytic activity for the triiodide/iodide (I_3^-/I^-) redox couple, but are poorly effective for iodine-free redox couple such as Co^{2+}/Co^{3+} and T_2/T^- . Transparent conducting oxides such as FTO or indium-tin oxide (ITO) on glass is the common substrate used in assembling DSSCs with different CE materials. The power conversion efficiency of DSSCs is governed by many factors including light absorbing capacity of photosensitizing dyes and catalytic materials.

The classical photosensitizing dyes were developed by Grätzel's research team,^{2,3} including N3 dye that absorbs up to 800 nm, and N749 dye (also known as black dye) which absorbs sunlight in the longer wavelength region up to 920 nm. In 2014, Mathew *et al.*⁴ used graphene nanoplatelets as a CE, a new push-pull porphyrin with a donor- π -bridge acceptor (D- π -A) chemical structure as a sensitizing dye, and Co(II)/Co(III) redox mediator for developing a DSSC, which exhibited a J_{sc} of 18.1 mA cm^{-2} , V_{oc} of 0.91 V, FF of 0.78 and the highest power conversion efficiency (PCE) of 13% under 100 mW cm^{-2} (AM 1.5) illumination. The high PCE of DSSCs originated from a molecularly engineered porphyrin dye, 4-(7-{2-[(2Z,7Z,11E,16Z)-7,17-bis[2,6-bis(octyloxy)phenyl]-12-bis[{4-[2,4-bis(hexyloxy)phenyl]phenyl}]amino]-21,23,24,25-tetraaza-22-zincahexacyclo[9.9.3.13,6.113,16.08,23.018,21]-pentacosa 1(20),2,4,6(25),7,9,11,13(24),14,16,18-undecane-2-yl]-ethynyl}-2,1,3-benzothiadiazole-4-yl)benzoic acid, coded as SM315 dye. The sensitizing dyes as a light harvester play a very significant role in achieving high PCE for DSSCs, therefore, dyes such as N3, N719, N749, Y123, Z907, JK-303 those absorb as much sunlight as possible is of a great interest, *i.e.*, Y123 dye = 3-[6-[4-bis(2',4'-dihexyloxybiphenyl-4-yl)amino]phenyl]-4,4-dihexylcyclopenta-[2,1-*b*:3,4-*b'*]dithiophene-2-yl]-2-cyanoacrylic acid; Z907 = *cis*-bis(isothiocyanato) (2,2'-bipyridyl-4,4'-dicarboxylato) (4,4'-di-nonyl-2'-bipyridyl)ruthenium(II); and JK-306 = (*E*)-3-{5'-[4-bis(2',4'-dihexyloxybiphenyl-4-yl)amino]phenyl}-2,2'-bithiophene-5-yl]-2-cyanoacrylic acid. The many types of dye-sensitizers such as ruthenium dyes, metal-free organic dyes, porphyrin dyes, quantum dots, and perovskites have been explored for DSSCs. Over the past 30 years, significant progress has been made in exploring diverse aspects of DSSC components, including dye-sensitizers, CEs, electrolytes and photoanodes, and many outstanding reviews are available in the literature on this exciting research topic.⁵⁻¹⁷ Chemical structures of photosensitizing dyes generally used in evaluating the photovoltaic performance of CEs in DSSCs are also discussed elsewhere. Many different types of Pt-free CE materials have been studied for DSSCs including carbon-based materials such as carbon black, mesoporous carbon, carbon nanotubes

(CNTs), carbon fibers, fullerenes, graphene-based materials, metals, transition metal oxides, sulfides, carbides, nitrides, selenides, tellurides, chalcogenides, layered double hydroxides, phosphides and their alloys, conducting polymers such as PEDOT:PSS and other composites materials.¹⁸⁻²²

Platinum (Pt) and ITO are the traditional materials used in fabricating different types of solar cell devices. In DSSCs, the Pt deposited on a FTO transparent conductive glass substrate is used as a CE for the reduction of triiodide (I_3^-) ions to iodide (I^-) ions. In this case, Pt acts as a catalyst for the regeneration of redox couples while FTO acts as an electron collector. Pt is a highly expensive metal which has been identified as one of the most critically important metals for the U.S. economic growth.^{23,24} Among electrocatalysts for DSSCs, Pt shows the best photovoltaic performance due to its high conductivity, chemical stability, and electrochemical activity but it is scarce. The current idea is to explore new alternative catalytic materials to replace the conventional Pt CE in DSSCs using easily available, inexpensive, highly electrically conductive, and high electrocatalytic activity materials. Earth-abundant 2D materials that offer high optical transparency and high electrocatalytic activity have been explored as potential candidate materials for CEs (cathode) and for replacing Pt in DSSC devices. During the last decade, graphene-based materials in the form of their thin films, nanosheets, fibers, multilayers, nanoplatelets, quantum dots, nanofoams and their nanocomposites with metals, CNTs, organic polymers, upconversion nanoparticles, titanium dioxide (TiO_2), ionic liquids, and halide perovskites, have been extensively investigated as Pt-free CEs for DSSCs²⁵ and heterojunction solar cells.^{26,27} The merit of graphene-based CEs in DSSC devices includes their high optical transparency, high electrical conductivity, large effective specific surface area, and the flexibility to fabricate them on different types of substrates.

Layered 2D TMDs are graphene analogs, therefore, research activities have been strongly diverted towards this new class of low-cost 2D materials. Among 2D TMDs, transition-metal disulfides and diselenides such as MoS_2 , $MoSe_2$, WS_2 , TiS_2 , $NbSe_2$, $TaSe_2$, $NiSe_2$, $FeSe_2$, $CoSe_2$, SnS_2 , Bi_2Se_3 and other TMD thin films have been investigated as CEs to fabricate Pt-free DSSCs. The CE acts as an electrocatalyst, and is one of the main components of a DSSC device which facilitates the reduction of triiodide (I_3^-) ions to iodide (I^-) ions in a redox electrolyte for dye generation. In this review, electrochemical and photovoltaic properties of low-cost catalytic CEs developed from earth-abundant TMDs and their composites with carbon, graphene, CNTs, carbon nanofibers, PEDOT:PSS and other materials are discussed. The impact of materials processing and morphology associated with PCEs of DSSCs has also been analyzed. Finally, this review discusses the electrochemical and environmental stability of TMDs-based CEs for DSSCs.

Hf, V, Nb, Ta, Tc, Re, Pd, Pt) and X is a chalcogen (S, Se, Te), such as MoS₂, WS₂, MoSe₂, WSe₂, form 2D layered structures and are abundantly available in nature. In a MX₂ monolayer structure (X–M–X), an atomic layer of a transition metal (M) is sandwiched between two chalcogen (X) atomic layers, where transition metal atoms (M) such as Mo and W are covalently bonded with chalcogen atoms (X) such as S, Se, Te. Each layer is 6–7 Å thick in the TMD layered structures. Weak van der Waals interactions occur between two adjacent MX₂ layers of TMDs, whereas the intra-layer M–X bonds are covalent.^{28–31} From an electrical point of view, MoS₂, MoSe₂, WS₂ and WSe₂ are semiconductors, WTe₂ and TiSe₂ are semimetals, VSe₂ and NbS₂ are metals, while NbSe₂ and TaS₂ are superconductors in their bulk crystalline forms.^{26,30} Geim and Grigorieva³² created a library of 2D materials (Table 1) where the 2D materials were classified into three different classes. Their graphene family includes graphene-based materials hBN, and BCN; the 2D chalcogenides include a large family of TMDs having insulator to semiconducting to metallic behavior; and the 2D oxides include layered oxides, perovskite-based materials, hydroxides, and others. The 2D TMDs include MoS₂, WS₂, VS₂, NbS₂, ZrS₂, TiS₂, NbSe₂, WSe₂, MoSe₂, ZrSe₂, WTe₂, and MoTe₂, and layered semiconductor chalcogenides such as GaSe, GaTe, InSe, Bi₂Se₃, and Bi₂Te₃. 2D materials represented by different colors denote their stability under ambient conditions. 2D materials among the graphene family have been extensively studied so far. 2D TMDs such as MoS₂, WS₂, WSe₂ and MoSe₂ are structurally similar. Among 2D TMDs, W based materials have stronger spin–orbit coupling while Se materials exhibit lower stability.

Research activities into 2D TMDs were intensified after the monolayers of MoS₂ showed high carrier mobility of 100 cm² V^{−1} s^{−1} and on/off current ratios of >10⁸ because of the interesting bandgap of MoS₂.³³ The monolayers of MoS₂ are direct semiconductors whereas MoS₂ bilayers, trilayers, few-layers are indirect semiconductors. Thickness dependent bandgap energies of 2D TMDs-based semiconductors, including MoS₂, MoSe₂, MoTe₂, WS₂, and WSe₂ (2H–MX₂), were calculated by

Yun *et al.*³⁴ using the first-principles calculations as shown in Fig. 1.³⁴ As the number of layers in the TMDs is reduced to a single layer, the band curvatures lead to significant changes of effective masses. When a single layer of the TMDs is strained, the direct bandgap turns to an indirect bandgap. It was found that bandgap energy and effective masses are reduced by tensile strain, contrary to the compressive strain that increases both parameters. Also the applied larger tensile stress gives rise to a metallic character. This study emphasized the electronic structures of 2D TMDs.

The photoluminescence and absorption spectra of monolayers of MoS₂, MoSe₂, WS₂, and WSe₂ have been measured.³⁵ TMDs as bulk crystals are indirect-bandgap semiconductors, however they become direct-bandgap semiconductors as their thickness is reduced to monolayers. The bandgap increases as the number of layers decreases. Photoluminescence peaks at

Fig. 1 Colored lines representing thickness dependence of bandgap energies of 2D TMDs including MoS₂, MoSe₂, MoTe₂, WS₂, and WSe₂ attain (2H–MX₂ semiconductors). 1.84 eV for MoS₂, 1.65 eV for WSe₂ and 1.56 eV for MoSe₂ have been observed.³⁶ The indirect bandgap at 1.2 eV for bulk crystals of WSe₂ was reported,³⁷ whereas the monolayer showed a photoluminescence peak at 1.65 eV (752 nm). In the case of bulk crystals of MoSe₂, the indirect bandgap was measured as 1.1 eV (1.13 μ m) while the monolayer exhibited a photoluminescence peak at 1.57 eV (792 nm). The photoluminescence emission peak for monolayer WS₂ appeared at 1.97 eV.³⁸

Mechanical exfoliation is the most common approach for peeling off monolayers or a few-layers of TMD materials from their bulk crystals,^{39–41} which is a top-down method. A second widely used approach is chemical vapor deposition (CVD), which is a bottom-up method to consecutively deposit desired thickness layers of TMDs.^{42–45} Other approaches for preparing layers of TMDs include chemical,⁴⁶ lithium intercalation,^{47–49} and ultrasonic-assisted liquid exfoliation in organic solvents,^{50–54} and salt-assisted liquid-phase exfoliation,⁵⁵ all of

which can prepare mono-layers to multi-layers of TMDs, such as MoS_2 , MoSe_2 , WS_2 , and WSe_2 .

Raman scattering methods for single-layer, multi-layer and bulk 2D TMDs, including MoS_2 , MoSe_2 , WS_2 , and WSe_2 , in terms of phonons with respect to the number of layers, has been reviewed and analyzed.^{56,57} Tonndorf *et al.*³⁷ studied photoluminescence and Raman characteristics of the monolayers of MoS_2 , MoSe_2 , and WSe_2 . Fig. 2a shows a schematic representation of the four Raman active modes and two Raman inactive modes of TMDs MX_2 ($\text{M} = \text{Mo}, \text{W}$ and $\text{X} = \text{S}, \text{Se}$) as predicted for the D6h point group.⁵⁸ The Raman active modes include three in-plane modes referred as E_{1g} , E_{2g}^1 , and E_{2g}^2 , and one out-of-plane mode referred as A_{1g} . However, experimentally only the two active Raman modes E_{2g}^1 and A_{1g} were observed. The active Raman E_{2g}^2 mode appears at very low frequencies, whereas the E_{1g} mode is forbidden.⁵⁹ A systematic study of the optical absorption of single-layer and few-layers of MoS_2 from the 385 nm (3.22 eV) to 1000 nm (1.24 eV) spectral range was conducted by Castellanos-Gomez *et al.*⁶⁰ using a hyperspectral imaging technique. Poly(dimethylsiloxane) (PDMS) was used as a transparent substrate for depositing mechanically exfoliated MoS_2 thin films. The optical absorbance spectra of MoS_2 flakes consisting of single-layer to six-layer were recorded as a function of different excitation wavelengths. The bandgap of a monolayer MoS_2 was measured as 1.85 eV, which decreased with increasing number of MoS_2 layers, reaching a bandgap value of 1.35 eV for the bulk MoS_2 . Fig. 2b and c shows Raman spectra for the E_{2g}^1 and A_{1g} modes of the exfoliated MoS_2 flakes ranging from single-layer to six-layer, and the variation of peak frequency difference (Δ) between the E_{2g}^1 and A_{1g} modes as a function of the number of MoS_2 layers. The Δ value increases with the increasing number of layers from 19.8 cm^{-1} for a single-layer to 25 cm^{-1} for bulk MoS_2 .

Raman spectroscopy for few-layer MoSe_2 nanosheets was recorded by Balasingam *et al.*⁶¹ which showed Raman peaks at 239 cm^{-1} and 287.11 cm^{-1} (Fig. 2d) corresponding to the A_{1g} mode (out-of-plane) and E_{2g}^1 mode (in-plane) of MoSe_2 , respectively. For bulk crystal MoSe_2 , the A_{1g} and E_{2g}^1 modes appear at 242 cm^{-1} and 286 cm^{-1} , respectively. The red shift in the A_{1g} mode and a blue shift in the E_{2g}^1 mode indicate the formation of a few-layered MoSe_2 nanosheet. Raman spectra of monolayers, few-layers and bulk WS_2 and WSe_2 were evaluated by Zhao *et al.*⁶² Thickness dependent Raman A_{1g} and E_{2g}^1 modes of 1 to 5 layers, as well as bulk WS_2 and WSe_2 , are shown in (Fig. 2e and f). As discussed above, the frequency difference (Δ) can be used to distinguish the number of layers. McCreary *et al.*³⁸ reported the E_{2g}^1 mode at 357.5 cm^{-1} (in-plane) and A_{1g} mode at 419 cm^{-1} (out-of-plane) with a frequency difference (Δ) of 61.5 cm^{-1} for WS_2 monolayer. Photoluminescence emission and Raman scattering of 2D TMDs have been extensively studied and analyzed by several research groups around the world.^{63–71}

morphology using a wide variety of spectroscopic techniques, including X-ray diffraction (XRD), Raman spectroscopy, X-ray photoelectron spectroscopy (XPS), UV-vis (Ultraviolet-visible) spectrometry, atomic force microscopy (AFM), field-emission scanning electron microscopy (FESEM), high-resolution transmission electron microscopy (HRTEM) and energy dispersive X-ray spectroscopy (EDX). The electrochemical catalytic activity and photovoltaic performance of CEs in DSSCs are evaluated using different methods. Electrocatalytic activity can be evaluated by cyclic voltammetry (CV), rotating disk electrode (RDE) for determining rate constant and effective catalytic surface area, interfacial charge transfer parameters (series resistance and charge-transfer resistance) measurements by electrochemical impedance spectroscopy (EIS) and Tafel polarization plots for electrocatalytic ability, incident photon-to-current conversion efficiency (IPCE) spectra measurements; these measurements of a DSSC device and their electro-catalytic activities are compared with a standard Pt CE. Photovoltaic tests of a DSSC device are performed by measuring photocurrent density–voltage (J – V) characteristic curves of CEs under a simulated solar illumination at 100 mW cm^{-2} (AM 1.5G) corresponding to 1 Sun intensity unless specified for other sunlight intensity. The photovoltaic and electrochemical parameters of the DSSC system include short-circuit photocurrent density (J_{sc}), open-circuit voltage (V_{oc}), fill factor (FF), power conversion efficiency (PCE) which is the solar-to-electricity conversion efficiency (η), series resistance (R_s), charge-transfer resistance (R_{CT}) at the CE/electrolyte interface, capacitance, and Nernst diffusion impedance (Z_N). When using a new material as a CE catalyst, the electrochemical and photovoltaic properties of a DSSC device are compared with a conventional Pt CE due to its optimal electrocatalytic activity and chemical stability in the electrolyte. The dye-adsorbed TiO_2 mesoporous film deposited on a FTO glass substrate is used as a photoanode (working electrode) of the DSSC device. The ruthenium N719 dye has been commonly used for the reduction of triiodide (I_3^-) to iodide (I^-). DSSCs are assembled with different CEs to be studied, and filled with the same redox electrolyte solution such as triiodide/iodide (I_3^-/I^-) redox couple. The CE reduces the triiodide (I_3^-) ions to iodide ions (I^-). For example, a typical iodide electrolyte solution contains 0.1 M of LiI , 0.05 M of iodine (I_2), 0.6 M of 1,2-dimethyl-3-*n*-propylimidazolium iodide (DMPII), and 0.5 M of 4-*tert*-butylpyridine (TBP) in acetonitrile. All these spectroscopic techniques and electrochemical measurements were performed, which have been discussed throughout this review as needed in order to evaluate the potential of 2D TMDs (such as MoS_2 , WS_2 , TiS_2 , FeS_2 , CoS_2 , NiS_2 , SnS_2 , MoSe_2 , NbSe_2 , TaSe_2 , NiSe_2 , FeSe_2 , CoSe_2 , Bi_2Se_3 and their based hybrids/composites) as CEs for fabricating low-cost Pt-free DSSCs.

3. TMD-based counter electrodes for DSSCs

The new materials used as CEs in DSSC devices are generally characterized by their molecular structure and surface

3.1 MoS_2 counter electrodes

3.1.1 Pristine MoS_2 . TMDs have been traditionally used as solid lubricants^{72–80} but recently have found the potential for applications in the fields of electronics and photonics. Like 2D graphene-based materials, layered transition-metal

dichalcogenides MX_2 ($\text{M} = \text{W}, \text{Mo}, \text{Hf}, \text{Nb}, \text{Re}, \text{Ta}$; $\text{X} = \text{S}, \text{Se}, \text{Te}$) have become of great interest due to their unique electronic and photonic properties and a very wide range of applications in field-effect transistors (FETs),^{81–99} photodetectors,^{100–102} light-emitting diodes (LEDs),^{103,104} ferroelectric memories,¹⁰⁵ static random access memory (RAM),⁸³ high-frequency resonators,¹⁰⁶ supercapacitors,^{107,108} energy conversion and storage devices,^{109–112} gas sensors,^{113,114} biosensors,^{115,116} biomedical applications,¹¹⁷ organic solar cells,¹¹⁸ and photonics/optoelectronics.^{119,120}

TMDs are one of the 2D graphene analogs which show great potential for both bulk-heterojunction (BHJ) and dye-sensitized solar cells. A review article on atomically thin MoS_2 layers used as the electron-transport layer (ETL), hole-transport layer (HTL), interfacial layer, and protective layer in fabricating bulk-heterojunction (BHJ) solar cells has been recently published by Singh *et al.*¹¹⁸ Here, the applications of MoS_2 thin films as CEs for fabricating Pt-free dye-DSSCs are discussed.

Polytypism in MoS_2 has been studied by using Raman spectroscopy.¹²¹ Layered MoS_2 exists in 2H, 3R and 1T phases where monolayers are stacked in a different sequence.^{122–124} The semiconducting 2H- MoS_2 phase of the bulk crystal contains two-layer per unit cell stacked in a hexagonal symmetry, where each Mo atom is coordinated with six sulfur (S) atoms. The 3R- MoS_2 phase contains three-layer per unit cell stacked in a rhombohedral symmetry. The metallic 1T phase contains one MoS_2 layer per unit cell in tetragonal symmetry with octahedral coordination. A structural phase transition of 2H- MoS_2 to 1T- MoS_2 (2H \rightarrow 1T) has been reported due to a lithium ion

intercalation process.^{122–125} The metallic 1T phase of MoS_2 exhibits very interesting electronic properties.^{126–129} Therefore, Wei *et al.*¹³⁰ used metastable 1T metallic phase MoS_2 in fabricating DSSCs. In that work, MoS_2 films were deposited on FTO glass substrate by a hydrothermal method, performing reactions at 180 or 200 °C for 24 hours. The MoS_2 films prepared at 200 °C showed lumps, while those grown at 180 °C had flower-like structures. High-angle annular dark-field scanning transmission electron microscopy (HAAD-FSTEM) images, Raman spectroscopy, and XPS also showed the formation of 2H and 1T metallic phases of MoS_2 . Fig. 3 represents the J - V curves of 2H- MoS_2 and flower-structured 1T metallic phase MoS_2 . The flower-structured 1T metallic MoS_2 film was grown onto an FTO substrate as a CE of DSSC, which exhibited PCE (η) of 7.08%, that is a three times higher PCE compared with 2H phase MoS_2 ($\eta = 1.72\%$) and comparable to a Pt CE ($\eta = 7.25\%$). Such a large difference in PCE values of 1T and 2H phases occurs because the electrical conductivity of 1T- MoS_2 is 10^7 times larger compared with 2H- MoS_2 , which gives rise to a higher electrocatalytic activity for the 1T phase than that of the 2H phase. The 1T- MoS_2 CE also demonstrated lower charge-transfer resistance (R_{CT}). The IPCE curves and CV measurements also showed a better electrocatalytic activity of 1T- MoS_2 CE in DSSC than that of 2H- MoS_2 .

A very interesting study was conducted by Infant *et al.*¹³¹ who developed CE materials for DSSCs by vertically oriented MoS_2 on an FTO substrate, in order to increase the reflectivity of MoS_2 CE. Fig. 4 shows high resolution SEM images of CVD-deposited MoS_2 thin films, the reflectivity of MoS_2 CE measured by UV-vis spectrophotometer, and CV measurements using standard hydrogen electrode (SHE) as a reference electrode. The high quality thin films of MoS_2 were obtained at the optimum conditions of 600 °C with a 15 minute reaction time at a flow rate of 50 sccm. The FTO substrate is damaged if temperature is increased above 600 °C and the reaction time is over 15 minutes, leading to excessive deposition of sulfur on the surface. The layered MoS_2 thin films are polycrystalline and have 0.18–0.27 nm spacing as evidenced by the TEM image and SEAD pattern. The CVD-prepared MoS_2 thin films are vertically oriented on the FTO substrate, which yields more active sites and eventually enhance the reflectivity so that more photons are absorbed, and also created active edge sites facilitating the generation of the I^-/I_3^- redox couple. The reflectance of vertically inclined MoS_2 films on the FTO substrate was measured by a UV-vis spectrophotometer between 350–800 nm wavelength for reaction temperatures varying from 400 to 700 °C, a reaction time ranging from 5 to 30 minutes, and different flow rates of Ar gas (Fig. 4). The maximum reflectance of 38% was observed for a vertically inclined MoS_2 thin film under optimized conditions, due to high crystallinity, and the inclined angle of 26° was estimated that supports the reflectivity of photons to dye molecules. The reflectivity of 38% was observed for MoS_2 thin films prepared at 50 sccm due to its crystallinity and higher inclination angle, which contributes to more absorption photons, and hence leads to a higher PCE of 7.50% compared to PCE of 7.38% for 150 sccm with 25% reflectivity, due to smaller angle of MoS_2 inclination. This approach yielded a PCE of 7.50% for the MoS_2 CE, exceeding the PCE of Pt based CE ($\eta =$

Fig. 3 Photocurrent density–voltage (J - V) curves of 2H-type MoS_2 and flower-structured 1T metallic phase MoS_2 . 7.28%). The MoS₂ CE shows a higher J_{sc} value of 15.2 mA cm⁻², and is higher than Pt CE ($J_{sc} = 14.6$ mA cm⁻²) due to high reflectivity. The R_{CT} of MoS₂ CE was lower than Pt CE, indicating the higher electro-catalytic activity of vertically inclined MoS₂ film on the FTO substrate was due to more active edge sites, which gives rise to enhanced electrocatalytic activity of the MoS₂ CE. Two redox peaks are observed in the CV curves of Pt and MoS₂ CEs, one corresponding to the reduction of I₃⁻, which is a cathodic peak (V_{pc}), and the other corresponding to the oxidation of I⁻, which is an anodic peak (V_{pa}). The value of anodic peak to cathodic peak separation (V_{pp}) was found to be less for the MoS₂ CE (0.456 V) than that of Pt (0.484 V), which also indicates a better electrocatalytic activity of MoS₂ CE due to the presence of active edge sites, as evidenced in the SEM images.

Vertical MoS₂ nanosheets on different substrates using CVD and CS₂ as a sulfur precursor have been developed.¹³² The DSSC CEs with vertical MoS₂ nanosheets showed a comparable electro-catalytic activity to Pt CE for the triiodide (I₃⁻) reduction, resulting from large specific surface areas and more active edges. Li *et al.*¹³³ prepared molybdenum disulfide-based CEs for DSSCs with different morphologies (multilayers, few-layers and nanoparticles) using the thermal decomposition method. The X-ray diffraction and transmission electron microscopy showed edge area to basal-plane ratio in the following order: MoS₂ nanoparticles > multilayered MoS₂ > few-layered MoS₂. A similar order was observed for the PCE values with corresponding CEs-based DSSCs. The MoS₂ nanoparticles-based CE had the minimum R_{CT} , while the few-layered MoS₂ based CE had the maximum, as measured by EIS. The active sites of MoS₂

responsible for the reduction of triiodide lie on the edges of layered materials, instead of their basal planes. MoS₂ nanoparticle CE showed the highest PCE value of 5.41%, compared with 6.58% of Pt CE. A novel approach for improving PCE of MoS₂ CE based DSSCs has been developed,¹³⁴ where electrocatalytic activity was enhanced by artificially generating active edge sites on MoS₂ atomic layers by hole patterning. The PCE of the DSSC increased from 2% to 5.8% after applying the hole patterning approach. Al-Mamun *et al.*¹³⁵ deposited MoS₂ nano-scale thin films onto FTO substrates using a low temperature one-pot hydrazine assisted hydrothermal method. Both the hydrothermal reaction temperature as well as the different molar ratio of reaction precursors was found to impact the structure and performance of MoS₂ films used as CEs for DSSCs. The MoS₂ thin films having surface exposed layered nanosheets were obtained by the hydrothermal process with a molar ratio of reaction precursors as 1 : 28 of (NH₄)₆Mo₇O₂₄·4H₂O and NH₂-CSNH₂ (thiourea) at 150 °C for 24 hours, referred to as MS-150-28. The molar ratio of (NH₄)₆Mo₇O₂₄·4H₂O and NH₂CSNH₂ was fixed at 1 : 7, 1 : 14, 1 : 28 and 1 : 42 and the hydrothermal temperature was maintained at either 120, 150, 180 or 210 °C. The DSSCs having MoS₂ CEs fabricated using different molar ratios of reaction precursors at a temperature of 150 °C (referred to as MS-150-7, MS-150-14, MS-150-28 and MS-150-42) exhibited PCEs of 3.70, 4.97, 7.41 and 4.96%, respectively. The DSSCs with MS-120-28, MS-180-28, and MS-210-28 CEs showed PCEs of 5.52, 7.15 and 5.47%, respectively. The MoS₂ film based CEs showed a PCE of 7.41%, higher than the Pt electrode based DSSCs (η = 7.13%) using TiO₂ photoanodes sensitized by N719 dye.

Pulse electrochemical deposited thin films of molybdenum sulfide (MoS_x) on indium tin oxide/poly(ethylene naphthalate) (ITO/PEN) substrates have been studied as flexible CEs for DSSC, and these showed a PCE of 4.39% for the triiodide (I₃⁻) reduction.¹³⁶ The nanostructured MoS₂ thin films developed by a low-temperature thermally reduced technique on a FTO substrate have also been used for DSSCs.¹³⁷ MoS₂ thin film annealed at 300 °C were also used as CEs for DSSCs, which showed a PCE of 6.351%, slightly lower than the Pt reference CE (η = 6.929%). The performance of DSSCs was impacted by the molar ratio of reaction precursors and the temperature of thermal reaction. Thermally reduced (TR) MoS₂ thin film annealed at 250 °C showed PCE of 1.917%, while those annealed at 350 °C showed PCE of 3.479%. The 300 °C annealed TR-MoS₂ CE also has larger exchange current density than those of 250 °C and 350 °C annealed TR-MoS₂ CEs and comparable with thermally deposited (TD) Pt CE. The R_{CT} values that correspond to the charge-transfer resistance at the electrolyte-electrode interface were 14.98 Ω cm² for TD-Pt CE and 30.98, 141.41 Ω cm² for TR-MoS₂ CEs annealed at 300 °C and 350 °C, respectively. TR-MoS₂ CEs annealed at 250 °C has no R_{CT} value being too large. The annealing temperature of 300 °C generates much larger active area, providing the highest electrocatalytic activity for the reduction of I₃⁻, while 350 °C annealing decreases the active sites of the edge-planes in MoS₂. A PCE of 7.01% was achieved for DSSCs using pristine MoS₂ as a CE, chemically synthesized by low-temperature wet-chemical process, which has a comparable PCE of 7.31% for DSSCs

with Pt CEs.¹³⁸ The R_s and R_{CT} values of 23.51 and 18.50 Ω cm², respectively, for the MoS₂ CE were lower than those of Pt CE (26.73 and 22.88 Ω cm²), suggesting better electro-catalytic activity of MoS₂ for the reduction of triiodide (I₃⁻).

A correlation between the electrical conductivity of the CE, PCE, and the crystallinity of MoS₂ was also demonstrated.¹³⁹ The XRD, XPS, EIS and Hall measurements established a link between the PCE, carrier concentration, mobility, and J_{sc} value. The DSSCs having pristine (non-annealed), vacuum-annealed and N₂-annealed MoS₂ CEs showed PCE values of 1.0, 1.7 and 0.8%, respectively. Thermal annealing in vacuum was found to reduce the over-potential that leads to an increased J_{sc} value of 7.95 mA cm⁻² due to high MoS₂ crystallinity, whereas the N₂-annealing of MoS₂ CEs increases over-potential, which gives rise to lower J_{sc} value of 4.35 mA cm⁻² due to the poor crystallinity of MoS₂. Interestingly, the electrical conductivity of MoS₂ CEs follows the order: N₂-annealed > vacuum-annealed > non-annealed MoS₂. This indicates that the PCE of the DSSCs is influenced by the over-potential that involves an electron transferring from the MoS₂ CE to the electrolyte, instead of the electrical conductivity of the CE. Antonelou *et al.*¹⁴⁰ reported the growth of monolayer and few-layer MoS₂ films by the sulfuration of molybdenum (Mo) foils at 800 °C. The few-layer thick MoS₂ films were used as CEs for DSSCs for the reduction of I₃⁻ to I⁻. The electrocatalytic activity of MoS₂ CE on flexible Mo substrates depends upon the number of monolayers in the DSSC. DSSCs having the MoS₂/Mo CE yield a PCE of 8.4%, close to Pt/FTO-based DSSCs (PCE of 8.7%). Stability of a three-monolayer thick MoS₂ CE was studied for 100 consecutive cycles, where no degradation of the peak current density was noticed for 100 repeated cycles, confirming long term electrochemical stability in an electrolyte solution. MoS₂ layers with 1–2 nm thickness showed long term chemical stability of the DSSC device for the electrolyte solution comparable to Pt CE. The increased number of active sites due to a grainy surface texture of Mo foil leads to the higher electro-catalytic activity of MoS₂ films.

A very interesting comparison was made by Wu *et al.*¹⁴¹ for chemically synthesized MoS₂ and WS₂ as CEs in the reduction of I₃⁻ to I⁻ and disulfide/thiolate (T₂/T⁻) based DSSCs. The R_{CT} values of 0.5 Ω cm² for MoS₂ and 0.3 Ω cm² for WS₂, respectively, compared with R_{CT} of 3.0 Ω cm² for Pt CE, indicates that both MoS₂ and WS₂ are as effective as CEs as standard Pt for triiodide (I₃⁻) reduction in DSSCs. The high FFs of 73% for MoS₂ CEs and 70% for WS₂ CEs also confirm high electro-catalytic activities for the reduction of triiodide (I₃⁻) to iodide (I⁻). Therefore, high PCE values of 7.59% for MoS₂ and 7.73% for WS₂ were observed, which are comparable to the PCE of 7.64% for Pt CEs in DSSCs under simulated AM 1.5 illumination. The Z_N of >100 Ω for triiodide (I₃⁻) reduction on the sulfide electrodes was found to be higher compared with a Z_N of 9.5 Ω on the Pt CE. The photocurrent density voltage (J - V) curves of the DSSCs having MoS₂, WS₂, and Pt based CEs for the triiodide/iodide (I₃⁻/I⁻) redox couple and disulfide/thiolate (T₂/T⁻) redox couple are shown in (Fig. 5). The TiO₂ film photoanode was obtained after pre-heating at 80 °C and immersing in a 5×10^{-4} M solution of N719 dye in acetonitrile/*tert*-butyl alcohol for 20 hours. The

Fig. 5 (a) Photocurrent density–voltage (J – V) curves of the DSSCs having MoS_2 , WS_2 , and Pt counter electrodes for triiodide to iodide (I_3^-/I^-) reduction. (b) J – V curves of the DSSCs using MoS_2 , WS_2 and Pt CEs for redox couple of disulfide/thiolate (T_2/T^-). Reprinted with permission from ref. 141, M. Wu, Y. Wang, X. Lin, N. Yu, L. Wang, L. Wang, A. Hagfeldt and T. Ma, economical and effective sulfide catalysts for dye-sensitized solar cells as counter electrodes. *Phys. Chem. Chem. Phys.*, 2011, **13**, 19298–19301. triiodide/iodide (I_3^-/I^-) electrolyte is made of 0.06 M of lithium iodide (LiI), 0.03 M of I_2 , 0.5 M of 4-*tert*-butyl pyridine, 0.6 M of 1-butyl-3-methylimidazolium iodide, and 0.1 M of guanidinium thiocyanate in acetonitrile. The 5-mercapto-1-methyltetrazole di-5-(1-methyltetrazole) disulfide/*N*-tetramethylammonium salt ($^+\text{NMe}_4\text{T}^-$) (T_2/T^-) electrolyte consists of 0.4 M of $^+\text{NMe}_4\text{T}^-$, 0.05 M of LiClO_4 , 0.4 M of di-5-(1-methyltetrazole) disulfide (T_2), and 0.5 M 4-*tert*-butylpyridine in acetonitrile and ethylene carbonate solution. For both DSSCs, a spray-coating technique was used for fabricating MoS_2 and WS_2 CEs. The J – V curves of the DSSCs having sulfide CEs and T_2/T^- electrolyte show PCE values of 4.97% for MoS_2 , 5.24% for WS_2 , and 3.70% for Pt CE. The PCE values were increased 36% for MoS_2 and 41% for WS_2 compared to the Pt CE, showing that DSSCs having MoS_2 and WS_2 are better than that of the Pt CE for the T_2/T^- redox couple.

The interfaced exfoliated MoS_2 thin films with different porphyrin molecules, where the MoS_2 was functionalized with zinc(II) porphyrin (ZnPP), showed a 10-fold increase in photocurrent compared to MoS_2 films.¹⁴² Exfoliated ultrathin porous MoS_2 sheets prepared by a tetraethylorthosilicate (TEOS)-assisted hydrothermal method were used as CEs in DSSCs.¹⁴³ The cyclic voltammograms and electrochemical impedance spectroscopy showed low R_{CT} and high electro-catalytic activity for porous MoS_2 sheets CEs in DSSCs, with a PCE of 6.35%, slightly better than that of Pt CEs ($\eta = 6.19\%$) under similar experimental conditions. A CE created by spin-coating of MoS_2 nanosheets followed by thermal treatment was also prepared.¹⁴⁴ DSSCs having MoS_2 nanosheets thermally treated at 100 °C showed a PCE value of 7.35%, comparable to conventional a Pt CE (7.53%). When MoS_2 nanosheets were thermally treated at 300 °C, the PCE value decreased significantly due to the transformation of MoS_2 to MoO_3 . MoS_2 films deposited on FTO glass using an RF sputtering method were also used as CEs for TiO_2 -based DSSCs.¹⁴⁵ CV, EIS, and Tafel polarization curve measurements conducted on the MoS_2 CE showed high electrocatalytic activity, low charge-transfer resistance as well as the fast reaction kinetics for triiodide (I_3^-) reduction. The MoS_2 CE prepared after 5 minutes of sputtering showed a PCE of 6.0%, comparable to Pt CEs ($\eta = 6.6\%$) in DSSCs. The PCE of DSSCs having MoS_2 CEs sputtered for 1, 3, 5 and 7 minutes were 5.7,

5.8, 6.0, and 5.2%, respectively. MoS_2 CEs were also developed by synthesizing MoS_2 films at 70 °C using molybdenum(V) chloride and thioacetamide, followed by near-infrared laser-sintering for 1 minute to enhance crystallinity and inter-connectivity between the MoS_2 particles.¹⁴⁶ The DSSC with laser-sintered MoS_2 CE exhibited a PCE of 7.19%, much higher than heat-sintered MoS_2 CE (5.96%) and comparable with a Pt CE ($\eta = 7.42\%$). The laser-sintered MoS_2 CE offers superior electro-catalytic activity for the triiodide (I_3^-) to iodide (I^-) redox couple. Also, a solution-phase process was used to grow MoS_2 nanofilms on FTO glass as a CE for a DSSC, which showed a PCE of 8.3%.¹⁴⁷ Finally, exfoliated and annealed $\text{MoS}_{2x}\text{Se}_2(1-x)$ as well as exfoliated- MoS_2 films were used as CEs.¹⁴⁸ The thickness and size of exfoliated MoS_2 nanosheets were 0.9 by 1.2 nm and 0.2 by 2 μm , corresponding to a single-layer. The MoS_2 based CE showed a PCE of 6%, compared to 5.1% for the annealed MoS_2 films.

3.1.2 MoS_2 /graphene composites. 2D TMDs based composites have been extensively investigated.^{149,150} Like graphene, MoS_2 can be mechanically exfoliated into nanosheets from its bulk crystals and used for studying electronics and photonic properties. These 2D layered materials can be combined into a single hybrid structure, so that both MoS_2 and graphene components can synergistically enhance photovoltaic properties. The nanocomposites of MoS_2 and graphene have been investigated as CEs for DSSCs.

To fabricate a Pt-free DSSC, Lin *et al.*¹⁵¹ used a MoS_2 /graphene nanosheet composite as a CE and nanocrystalline TiO_2 as a photoanode. The redox electrolyte solution in the DSSC was made of 1 M 1,3-dimethylimidazolium iodide, 0.15 M iodine, 0.5 M 4-*tert*-butylpyridine and 0.1 M guanidine thiocyanate in 3-methoxypropionitrile. The MoS_2 /graphene nanosheet based CE showed a PCE of 5.81%, in comparison to a PCE of 6.24% for the conventional sputtered Pt CE. Yue *et al.*¹⁵² used a MoS_2 /graphene flake composite film as the CEs for DSSCs with N719 dye for the reduction of triiodide (I_3^-) to iodide (I^-). The MoS_2 powder (ARCOS, 99%) and 8 nm flakes of multi-layer graphene nanopowder (Uni-Onward Corp., 99.5%) were mixed in specific ratios to prepare the composites. The electrocatalytic activity increased after adding graphene flakes to the MoS_2 film.

Charge-transfer resistances (R_{CT}) of $3.98 \Omega \text{ cm}^2$ for graphene, $2.71 \Omega \text{ cm}^2$ for MoS_2 , $2.09 \Omega \text{ cm}^2$ for $\text{MoS}_2/\text{graphene}$, and $2.01 \Omega \text{ cm}^2$ for Pt CEs were measured. The current density of the $\text{MoS}_2/\text{graphene}$ composite CE was recorded to be higher than that of the MoS_2 , graphene and Pt CEs. The J - V characteristics of the DSSCs having $\text{MoS}_2/\text{graphene}$ as CEs and ranging in thickness from single-layer to six-layer were investigated and compared with conventional Pt CEs. The thickness of the $\text{MoS}_2/\text{graphene}$ layers affected the PCE of the DSSCs, and J_{sc} and V_{oc} increased with increasing number of plaster layers from single to 3-layer, and, thereafter, a decrease was noticed for 4-layers and 5-layers. The effect of graphene content was also studied, where, the R_{CT} was found to decrease for the $\text{MoS}_2/\text{graphene}$ CE, from 0.5 wt% to 1.5 wt% of graphene content. The PCE of the $\text{MoS}_2/\text{graphene}$ composite CE having 1.5 wt% graphene was 5.98%, compared to the PCE of 6.23% for Pt CE. Yu *et al.*¹⁵³ used MoS_2 nanosheets and graphene composites for fabricating CEs for the triiodide (I_3^-) reduction. Graphene thin films were prepared by the chemical vapor deposition (CVD) technique in combination with a hydrothermal process. MoS_2 nanosheets with 210 nm thickness were *in situ* grown on FTO glass substrate, and uniformly dispersed on the surface of a graphene film. Fig. 6 shows the morphology of the synthesized graphene- MoS_2 composites, using field-emission scanning electron microscopy (FESEM) and high-resolution transmission electron microscopy (HRTEM) with different magnifications. The thickness of the graphene film was found to be 2.48 nm by atomic force

microscopy, which corresponds to seven layers of graphene. The top-view FESEM images of graphene- MoS_2 hybrids showed fully covered graphene film with 5 to 20 nm thick MoS_2 nanosheets. The nucleation and growth of MoS_2 nanosheets depends upon the graphene film. Graphene films play an active role for higher electrical conductivity by speeding up the charge transfer process and generating active sites for dispersion and integration of MoS_2 nanosheets. The presence of MoS_2 nanosheets increases the electrode-electrolyte contact area, and therefore helps in improving the electrocatalytic activity. The low R_{CT} of $1.5 \Omega \text{ cm}^2$ for $\text{MoS}_2/\text{graphene}$ CE, $1.7 \Omega \text{ cm}^2$ for MoS_2 , $1.70 \Omega \text{ cm}^2$ for graphene, and a high R_{CT} of $2.1 \Omega \text{ cm}^2$ for a Pt CE, indicates better interaction and contact formation of MoS_2 nanosheets and graphene film with fluorine doped tin oxide (FTO) substrates and a fast charge transfer. The FF of graphene is 24% compared to a FF of 65% for MoS_2 , however when both materials are combined into a composite system, the FF raises to 68%. Therefore, MoS_2 nanosheet/graphene composite CEs resulted in a higher PCE of 7.1% because of the synergetic interactions between graphene and MoS_2 , compared to the low PCE values of 2.8% for graphene and 5.6% for MoS_2 , and a comparable PCE of 7.4% for Pt reference CEs. $\text{MoS}_2/\text{graphene}$ based CEs in a DSSC offer higher electrocatalytic activity for triiodide (I_3^-) reduction induced by the synergetic interactions. Fig. 7 represents the J - V characteristics of DSSCs having graphene- MoS_2 as CEs with increasing number of layers¹⁵² and

graphene-MoS₂ nanosheet based CEs for the triiodide (I₃⁻) reduction.¹⁵³

MoS₂ nanosheets/graphene electrodes were also studied by Lynch *et al.*¹⁵⁴ the PCE of 95% of the Pt electrode was achieved after adding 10 wt% MoS₂ nanosheets to a graphene film CE. This again confirms that the MoS₂ nanosheet/graphene composite ECs have higher catalytic activity than graphene CEs, though the graphene nanosheets contribute to higher electrical conductivity in the composite. An electrochemical strategy¹⁵⁵ was used for preparing MoS₂/graphene composite as CEs of DSSCs, which included electro-deposition and electro-reduction of graphene oxide, and thereafter electro-deposition of MoS₂ on reduced graphene oxide (GO) layers. The MoS₂/graphene composites were characterized by SEM, TEM and Raman spectroscopy. The MoS₂/graphene CEs based DSSCs exhibited a PCE of 8.01%, comparable to a PCE of 8.21% for the Pt CE. In another study, nanocomposites of MoS₂ and nitrogen-doped graphene oxide (N-GO) were used as a CE for DSSCs.¹⁵⁶ The MoS₂/N-GO nanocomposites were characterized by HRTEM, XPS, and Raman spectroscopy, and their electrochemical properties were evaluated by EIS, CV, and Tafel measurements. The MoS₂/N-GO nanocomposite formation offered high specific surface area of N-GO and many edge sites of MoS₂. The MoS₂/N-GO nanocomposite based CE exhibited a PCE of 5.95%, lower than the standard Pt CE (PCE of 6.43%).

Composite films of MoS₂ with nitrogen-doped graphene (N-graphene) were prepared using a drop-coating method and used as a CE of DSSCs.¹⁵⁷ The N-graphene supported an increase in electrical conductivity, whereas MoS₂ increased the electrocatalytic activity in the composite thin film. The N-graphene/MoS₂ composite film showed a PCE of 7.82%, lower than the Pt CE ($\eta = 8.25\%$) based DSSC. The electrocatalytic capability of N-graphene/MoS₂ composite films for the triiodide (I₃⁻) reduction was much higher compared with pristine N-graphene and MoS₂ thin films, as studied using CV, RDE, the Tafel polarization curve, and EIS. The graphene flakes (GF) into a nanosheet-like MoS₂ matrix were dispersed using an *in situ* hydrothermal

method, and used a MoS₂/GF hybrid as a CE to fabricate Pt-free DSSCs.¹⁵⁸ The incorporation of GFs into the MoS₂ matrix was confirmed using scanning electron microscopy (SEM), transmission electron microscopy (TEM), XRD, and Raman spectroscopy. The electrochemical measurements showed improvement in the electrocatalytic activity after the GFs were integrated into the MoS₂ matrix, where the hybrid containing 1.5 wt% of graphene flakes exhibited the highest electrocatalytic activity. The DSSC with the MoS₂/GF hybrid CE showed a PCE of 6.07%, which was 95% of the Pt CE ($\eta = 6.41\%$).

3.1.3 MoS₂/carbon nanotubes composites. Carbon nanotubes (CNTs) are one of the most interesting materials because they offer high optical transparency, high electrical conductivity, high mechanical strength, and high thermal stability, and therefore CNTs have been studied as CEs for DSSCs. It is of great interest to combine the unique properties of both MoS₂ and CNTs into a single hybrid system which could synergistically enhance the electrocatalytic activity of a DSSC system. Yue *et al.*¹⁵⁹ used a flower-like structure of MoS₂/single-wall carbon nanotubes (MoS₂/SWCNTs) as CE catalyst for DSSCs, synthesized using a glucose and PEDOT:PSS assisted (G-P-A) hydrothermal process. The flower-like structure and surface morphology of the (G-P-A) MoS₂/SWCNTs was confirmed by SEM and TEM techniques. The DSSC having (G-P-A) MoS₂/SWCNTs CE exhibits a lower R_{CT} of 1.46 $\Omega\text{ cm}^2$ compared to the R_{CT} of 2.44 $\Omega\text{ cm}^2$ for the Pt electrode. The PCE reached 8.14%, better than that of the Pt-based DSSC (7.78%) with the iodide/triiodide (I₃⁻) electrolyte. The speedy reduction of triiodide (I₃⁻) to iodide (I⁻) by the (G-P-A) MoS₂/SWCNTs CE is attributed to the fast transport of the electrolyte *via* the flower-like structure. The MoS₂ and multi-walled carbon nanotube (MWCNTs) nanocomposites were employed as a CE in DSSCs for the reduction of triiodide (I₃⁻).¹⁶⁰ The microstructure of the MWCNTs@MoS₂ nanocomposite studied by transmission electron microscopy (TEM) confirmed the deposition of few-layers MoS₂ nanosheets on the MWCNTs surface. A MWCNTs@MoS₂ composite based CE resulted in higher

Fig. 7 (a) *J*-*V* characteristics of DSSCs having MoS₂/graphene as counter electrodes with different thickness ranging from single-layer to six-layer and a comparison with sputtered Pt counter electrode (PEC of 6.23%). Copyright© Elsevier.

cathodic current density than those of MWCNTs, MoS₂, and Pt CEs. The MWCNTs@MoS₂ CE showed a low charge-transfer resistance of 1.69 Ω cm² and no degradation up to 100 repeated cyclic voltammogram tests. The DSSC having a MWCNTs@MoS₂ composite CE exhibited a PCE of 6.45%, slightly better than that of the DSSC having sputtered Pt CE (η = 6.41%). The MWCNT@MoS₂ based CE also showed improved catalytic activity for the reduction of I₃[−].

The MoS₂ nanosheets anchored onto the CNT surfaces were used in Pt-free CEs for DSSCs.¹⁶¹ The MoS₂ nanosheets offer edge-plane electrocatalytically active sites for the reduction of I₃[−]. The large surface area of CNTs supports the loading of MoS₂ nanosheets in order to increase the electrochemical activity. The CNTs deposited onto the FTO substrate promoted charge transport, leading to a higher exchange current density and also to the lower charge-transfer resistance. The MoS₂/CNT hybrid based DSSCs achieved a PCE of 7.83%, which is 9.5% higher than that of the Pt CE (η = 7.15%) based DSSC.

Another research group¹⁶² used flower-like MoS₂ and a multi-walled carbon nanotubes (MoS₂/MWCNTs) hybrid as a CE for dye-sensitized solar cells. The flower-like MoS₂/MWCNTs hybrid contains a large specific surface area and lamellar structure, as evidenced by field emission scanning electron microscopy (FESEM). The optimized MoS₂/MWCNTs has a R_{CT} of 2.05 Ω cm² and series resistance (R_s) of 1.13 Ω cm² as measured by electrochemical impedance spectroscopy. Cyclic voltammogram measurements showed larger current density for MoS₂/MWCNTs based CEs than those of MoS₂, MWCNTs, and Pt CEs.

MoS₂/MWCNTs CE based DSSCs exhibited a PCE of 7.50%, comparable with the DSSC based on the Pt CE (η = 7.49%). A carbon nanotubes–MoS₂–carbon (CNTs–MoS₂–carbon) hybrid was prepared using wet impregnation and calcination with polyethylene glycol as a CE for DSSCs.¹⁶³ Spectroscopic characterization by Raman spectra, XRD, TEM, XPS, BET and thermal methods indicated a homogenous coating of CNTs with thin layers of MoS₂, as a result of wetting and emulsification of polyethylene glycol 400. The CNTs–MoS₂–carbon heterostructure was used as CEs for DSSCs, and showed high stability and electrocatalytic activity in the reduction of I₃[−] to I[−] because of low R_{CT} . Interestingly, a PCE of 7.23% achieved for the CNTs–MoS₂–carbon CEs based DSSC was higher than Pt CEs (η = 6.19%).

In another study, nanocomposites of MoS₂ and CNTs using a glucose aided (G–A) hydrothermal method were prepared by Yue *et al.*¹⁶⁴ The (G–A)MoS₂/CNTs nanocomposites obtained by adding 0.5, 1.0, 1.5, 2.0 and 2.5 wt% of acid-treated CNTs were deposited onto a FTO substrate and used as CEs in DSSCs for the reduction of triiodide (I₃[−]) to iodide (I[−]). The dye-sensitized TiO₂ anode was prepared by dipping the TiO₂ anode in 0.3 mM of dye N719 ethanol for 24 hours. Fig. 8 shows the SEM images of MoS₂ nanopowder and MoS₂–MWCNTs composites, J – V characteristics of the DSSCs fabricated with MoS₂, MoS₂/C, (G–A)MoS₂/CNTs and Pt CEs, and the effect of CNT contents on the PCE of the DSSCs using (G–A)MoS₂/CNTs. Scanning and transmission electron microscopy showed tentacle-like structures of the MoS₂/CNTs composites, having large active surface area and

Fig. 8 Scanning electron microscopic image of MoS₂ nanopowder and MoS₂–MWCNTs composites prepared by glucose aided (G–A) hydrothermal method. Photocurrent–voltage (J – V) characteristics of the DSSCs fabricated with MoS₂, MoS₂/C, (G–A)MoS₂/CNTs and Pt CEs. Relationship between the contents of CNTs in (G–A)MoS₂/CNTs CE and the PCE of DSSCs. Reprinted with permission from ref. 164, G. Yue, W. Zhang, J. Wu and Q. Jiang, glucose aided synthesis of molybdenum sulfide/carbon nanotubes composites as counter electrode for high performance dye-sensitized solar cells. *Electrochim. Acta*, 2013, **112**, 655–662. Copyright© Elsevier.

interconnected networks for fast transport for the electrolyte. The CNTs functionalized with a $-\text{COOH}$ functional group were used and MoS_2 was anchored onto the functionalized CNTs. The (G-A) MoS_2/CNTs had specific surface area of $411.7 \text{ m}^2 \text{ g}^{-1}$ and exhibited a small overpotential and better conductivity. The Nernst diffusion impedance (Z_w) values of $1.85 \Omega \text{ cm}^2$ for (G-A) MoS_2/CNTs CEs and $2.25 \Omega \text{ cm}^2$ for Pt CEs were measured, which indicates that the (G-A) MoS_2/CNTs catalyst accelerated the reduction of triiodide ions (I_3^-) to iodide ions (I^-). The (G-A) MoS_2/CNTs based CEs were found to exhibit enhanced electrocatalytic activity as evidenced by the CV, EIS, and Tafel polarization measurements. The photovoltaic performance of the DSSCs having MoS_2 , MoS_2/C , (G-A) MoS_2/CNTs , and Pt CEs were compared. The photovoltaic performance of (G-A) MoS_2/CNTs CEs were also studied as a function of the CNT contents. The PCE of the DSSCs increased as the contents of the CNTs increased from 0 to 1.5 wt%, however, further increase in CNT content leads to a decreased PCE. Likely, the maximum photovoltaic performance of the (G-A) MoS_2/CNTs CE in the DSSCs was achieved for a film thickness of $12 \mu\text{m}$. The (G-A) MoS_2/CNTs composite CE has a lower R_{CT} of $1.77 \Omega \text{ cm}^2$ at the electrolyte/electrode interface than those of MoS_2 , $\text{MoS}_2/\text{carbon}$ and conventional sputtered Pt CEs, and a PCE of 7.92% higher than the PCE of 7.11% for the Pt electrode in DSSCs for the triiodide/iodide (I_3^-/I^-) system. Lin *et al.*¹⁶⁵ fabricated nanocomposites of $\text{MoS}_2/\text{reduced graphene oxide (RGO)}$ with CNTs using electrophoretic deposition. The $\text{MoS}_2/\text{RGO-CNTs}$ hybrid was then used as a CE in DSSCs. In this hybrid, CNTs offer conductive networks for electron transport to increase the rate of charge-transfer at the CE/electrolyte interface. The $\text{MoS}_2/\text{RGO-CNTs}$ hybrid CEs show improved electrocatalytic activity

in comparison with the MoS_2/RGO alone. The DSSC having a $\text{MoS}_2/\text{RGO-CNTs}$ hybrid CE achieved a PCE of 7.46%, exceeding PCE values of DSSCs containing MoS_2/RGO CE ($\eta = 6.82\%$) and Pt CE ($\eta = 7.23\%$). Thin films of $\text{MoS}_2/\text{carbon}$ nanotube composites have also been applied as electrodes for lithium ion batteries.¹⁶⁶

3.1.4 $\text{MoS}_2/\text{TiO}_2$ composites. $\text{MoS}_2/\text{TiO}_2$ heterostructures were developed by Du *et al.*¹⁶⁷ by depositing few-layer MoS_2 on mesoporous TiO_2 by a chemical-bath method. Raman spectrum and HRTEM images indicated a few-layer structure of the MoS_2 . After few-layer MoS_2 deposition, the UV absorption spectra of the TiO_2 photoanode showed enhanced absorption in the visible wavelength region and a PCE of 1.08% for the $\text{MoS}_2/\text{TiO}_2$ based DSSC. Photovoltaic performance of the DSSC was found to be optimized by both thermal annealing and the thickness of the MoS_2 sensitized layer. Jhang *et al.*¹⁶⁸ modified the interface of a MoS_2 CE/electrolyte by incorporating TiO_2 nanoparticles, in order to control the overpotential loss. Their $\text{MoS}_2/\text{TiO}_2$ nanocomposite had a weight ratio of 5 : 1. Thermal annealing of the MoS_2 and $\text{MoS}_2/\text{TiO}_2$ CEs was performed at 400°C in vacuum for 2 hours. Fig. 9 shows the $J-V$ curves for MoS_2 , $\text{MoS}_2/\text{TiO}_2$, and Pt CEs in the DSSCs. The addition of TiO_2 nanoparticles into the MoS_2 CE significantly increased the J_{sc} value from 7.24 mA cm^{-2} for the MoS_2 CE to 13.76 mA cm^{-2} for the $\text{MoS}_2/\text{TiO}_2$ CE. The $\text{MoS}_2/\text{TiO}_2$ CE based DSSC ($\eta = 5.08\%$) shows two times better photovoltaic performance compared with the MoS_2 CE (2.54%) and comparable to the Pt CE (5.27%), because of an increased active surface area from the incorporated TiO_2 nanoparticles and the low overpotential loss. Though the $\text{MoS}_2/\text{TiO}_2$ CE exhibited high PCE, its electrical conductivity was found to be lower compared to the MoS_2 CE, and, therefore, the high electrocatalytic activity was not related to its electrical conductivity.

The $\text{MoS}_2/\text{TiO}_2$ based CE doped with different Co contents for the DSSCs were found to influence the PCE by improving electrocatalytic activity.¹⁶⁹ The Co content-optimized $\text{MoS}_2/\text{TiO}_2$ CE had enhanced catalytic activity at the electrolyte interfaces. The Co 3d orbit plays a role in increasing in the reduction of I_3^- to I^- . The photoanodes were developed using MoS_2 and TiO_2 nanoparticles.¹⁷⁰ The DSSCs with $\text{MoS}_2@\text{TiO}_2$ photoanode showed a PCE of 6.02%, 1.5 times higher than that of the TiO_2 film photoanode ($\eta = 4.43\%$).

3.1.5 $\text{MoS}_2/\text{carbon}$ composites. A very interesting study on $\text{MoS}_2/\text{carbon}$ composites was conducted by Yue *et al.*¹⁷¹ who developed DSSCs using MoS_2 and carbon composites as a CE with different contents of carbon. Fig. 10 represents the SEM images of hydrothermally synthesized MoS_2 and a porous MoS_2 -carbon hybrid, a HRTEM image of MoS_2 -carbon hybrid, an IPCE spectra, and $J-V$ curves of the DSSCs with MoS_2 , MoS_2 -carbon hybrid, and Pt CEs. The commercial MoS_2 particles have lamellar structure with large surface area. The hydrothermally prepared MoS_2 and MoS_2 -carbon hybrid contains a large number of interlaced nanosheets. The intercalated nanosheets in the MoS_2 -carbon hybrid are thinner compared with MoS_2 , indicating an increase in the specific surface area, which is highly suitable for improving the electrocatalytic activity. The MoS_2 and MoS_2 -carbon hybrid CEs were characterized by CV,

EIS, and Tafel polarization curve measurements, and compared with the Pt CE. IPCE spectra of MoS₂, MoS₂-C, and Pt CEs in DSSCs measured in the 300–750 nm range show a similar photoelectric response. A strong photoelectric peak in the IPCE spectra appears at 340 nm. DSSCs with MoS₂ CE show the highest photoelectric response of 44.6% in the IPCE spectra at 520 nm, which is lower compared to a DSSC having a Pt CE (60.9%). Interestingly, in the IPCE spectra of the DSSC having porous MoS₂-carbon CE, the highest photoelectric response of 67.3% is observed at 520 nm, which is higher than that of the Pt CE based DSSC. If one compares the R_{CT} values of 4.13 $\Omega\text{ cm}^2$ for MoS₂ and 2.29 $\Omega\text{ cm}^2$ for Pt electrodes, the MoS₂/carbon electrode had a low R_{CT} value of 2.07 $\Omega\text{ cm}^2$, appearing as a result of the high conductivity and large surface area for the MoS₂/

carbon composite, which eventually contributes to enhanced electrocatalytic activity of the CE. The R_{CT} values of the MoS₂/carbon electrode are also influenced by the carbon content, which decreases with the increase in carbon content, from 3.60 $\Omega\text{ cm}^2$ for 1.13 wt% carbon to 2.07 $\Omega\text{ cm}^2$ for 3.30 wt% carbon. Thereafter, the R_{CT} values increased from 2.40 $\Omega\text{ cm}^2$ for 4.35 wt% carbon content to 3.13 $\Omega\text{ cm}^2$ for 5.38 wt% carbon content. PCE values of 6.01, 7.03, 7.69, 7.33 and 5.76% were measured for MoS₂-carbon electrodes having 1.13, 2.23, 3.30, 4.35 and 5.38 wt% of carbon content, respectively. The highest value of 7.69% was achieved at 3.30 wt% carbon content in a MoS₂/carbon composite CE based DSSC for the I^-/I_3^- redox reaction, and exceeded the PCE value of 6.74% for a Pt CE under similar experimental conditions. PCE values of the DSSCs were also

Table 2 Photovoltaic parameters of MoS₂ based counter electrodes (CEs) used for DSSCs. FTO glass is the common substrate used in assembling DSSCs with different CE materials. The measurements were conducted at a simulated solar light intensity of 100 mW cm⁻² (AM 1.5G) unless specified. The photovoltaic parameters short-circuit photocurrent density (J_{sc}), open-circuit voltage (V_{oc}), fill factor (FF), power conversion efficiency (η), series resistance (R_s), charge-transfer resistance (R_{CT}), electrolyte and dye used of DSSCs of graphene/MoS₂ nano-composites are summarized and compared with standard Pt counter electrode^a

^a Disulfide/thiolate (T₂/T⁻) redox couple. In the case of R_s and R_{CT} : some of the authors used Ω instead of Ω cm² for the resistances without mentioning the size of the electrode.

found to vary as a function of the thickness of MoS₂/carbon CE. PCE values of 5.10, 6.89, 7.69, 7.01 and 4.85% were measured for the CE thicknesses of 4, 8, 12, 16 and 20 μ m for the MoS₂/carbon CE. EIS, CV, and Tafel curve analysis showed low R_{CT} , high electrocatalytic activity, and faster reduction of triiodide (I₃⁻) to iodide (I⁻) for the MoS₂/carbon CE compared to that of the Pt CE.

In yet another study, MoS₂/carbon fibers were used as CEs for DSSCs.¹⁷² Both electrocatalytic activity and the PCE (3.26%) of

the MoS₂/carbon fiber based CE was found to be better than that of Pt/carbon fiber CE (η = 2.93%). In another study, composites of flower-like MoS₂ microspheres and carbon materials such as vulcan carbon, acetylene black, MWCNTs, carbon nanofibers (CNFs), and rice husk ash were studied as cost-effective Pt-free CEs for DSSCs.¹⁷³ The electrolyte used in the DSSC was a phthaloylchitosan-based polymer. The carbon materials/MoS₂ CEs showed low R_{CT} at the CE/electrolyte interface and high electro-catalytic activity for I₃⁻ reduction. The DSSC with MoS₂/

CNF CE showed a PCE of 3.17%, compared to a PCE of 1.04% for the pure MoS₂ CE.

Another study used MoS₂ and PEDOT:PSS composites as CEs for DSSCs.¹⁷⁴ The MoS₂/PEDOT:PSS composite CE exhibits a PCE of 5.7% and FF of 58%, comparable to the Pt CE. The high PCE of the MoS₂/PEDOT:PSS CE originated from high electrocatalytic activity of the MoS₂ active sites for triiodide (I₃[−]) reduction and high conductivity of PEDOT:PSS. The inorganic/organic MoS₂/PEDOT:PSS composite may be useful as a low-cost Pt-free CEs for DSSCs. Another study used Bi₅FeTi₃O₁₅ (BFTO) nanofibers of 40–100 nm diameter developed by a sol-gel aided electrospinning method.¹⁷⁵ The MoS₂/BFTO nanocomposite-based CE for DSSCs was prepared by uniformly dispersing MoS₂ nanoparticles into the BFTO matrix. The optical bandgap of the MoS₂/BFTO nanocomposites was found to decrease with increasing MoS₂ contents. The DSSC with a MoS₂/BFTO nanocomposite-based CE showed a PCE of 5.20%, 24 times higher than that of the pure BFTO nanofiber based CE. Table 2 summarizes the electrochemical and photovoltaic properties of all types of MoS₂ based CEs discussed in this section above, and a comparison is made with conventional Pt CEs for DSSCs.

3.2 WS₂ counter electrodes

Tungsten disulfide (WS₂), traditionally used as a lubricant, is a semiconductor having van der Waals bonding which forms 2D layered-structures similar to other TMDs. WS₂ can form atomically thin nanosheets,^{176,177} nanorods,¹⁷⁸ and nanotubes,^{179,180} which have been actively studied for potential applications.

Carbon-coated WS₂ CEs have been fabricated for DSSCs at low temperature and characterized using FESEM, XRD, and Raman spectroscopy.¹⁸¹ The electrocatalytic activity of the WS₂ CEs was studied using CV and EIS. The DSSCs with carbon-coated WS₂ CEs show a PCE of 5.5%, comparable to that of Pt CE based DSSCs ($\eta = 5.6\%$). A DSSC having plastic WS₂ CEs exhibited a PCE of 5.0%. Carbon-coated WS₂ seems promising to develop low cost Pt-free CEs for DSSCs. The WS₂ films were

deposited by radio frequency (RF) sputtering and a sulfurization process as CE for DSSCs.¹⁸² The WS₂ films were characterized using XRD, FESEM, Raman spectroscopy, and XPS techniques. The transparent WS₂ CEs demonstrated high electrocatalytic activity and fast reduction of triiodide, (I₃[−]) as characterized using CV, EIS, and Tafel polarization curve. WS₂ CE sputtered for 10 minutes showed a PCE of 6.3%, slightly lower than the Pt-based CE ($\eta = 6.64\%$) used in the DSSC. The *J*-*V* characteristics as a function of sputtering time used to prepare WS₂ films as a CE were also studied. WS₂ film CEs prepared at sputtering time of 5, 10 and 15 minutes showed PCEs of 5.4%, 6.3% and 5.8%, respectively.

Another research team¹⁸³ used edge-oriented WS₂ based CEs for DSSCs. Edge-oriented WS₂ was obtained from mesoporous interconnected WO₃ structures using a high temperature sulfurization process. The DSSCs with edge-oriented WS₂ CEs show a PCE of 8.85%, higher compared to the Pt CE ($\eta = 7.20\%$). The large number of active edge sites in edge-oriented WS₂ is responsible for high electrocatalytic activity for the reduction of triiodide (I₃[−]) in the DSSCs. The WS₂ films were fabricated by the doctor-blade method (or tape casting method; a method removing excessive liquid material using a moving blade for uniform coating) to use as CEs for DSSCs.¹⁸⁴ The TiO₂ (P25) and carbon nanoparticles were introduced into WS₂ films to increase electrical conductivity and bonding strength. The electrochemical catalytic activity of WS₂/P25/C CEs was compared with Pt for the triiodide (I₃[−]) to iodide (I[−]) electrolyte system using CV and EIS measurements. The DSSC developed with WS₂/P25/C CE was shown to yield a PCE of 4.56%.

Yue *et al.*¹⁸⁵ prepared WS₂ decorated multi-walled carbon nanotubes (MWCNTs) by applying a hydrothermal method, for use as a low-cost Pt-free CE for DSSCs. The contents of MWCNTs in MWCNTs-WS₂ CEs varied from 1 to 10 wt%. PCE values of 5.20, 5.45, 6.41, 5.53 and 5.22% were measured in the DSSCs for CEs having 1, 3, 5, 7 and 10 wt% contents of MWCNTs, respectively. CV and EIS showed high electrocatalytic activity for the MWCNTs-WS₂ CE for the triiodide (I₃[−]) reduction. The *R*_{CT}

Fig. 11 (Left) SEM images of (a) WS₂, (b) MWCNTs, and (c and d) WS₂/MWCNTs composites. (Right) photocurrent–voltage (*J*-*V*) curves of the DSSCs with Pt, WS₂, MWCNTs, WS₂/MWCNTs* (prepared without glucose aid), and (G–A)WS₂/MWCNTs counter electrodes under a simulated solar illumination of 100 mW cm^{−2}. Reprinted with permission from ref. 186, J. Wu, G. Yue, Y. Xiao, M. Huang, J. Lin, L. Fan, Z. Lan and J. Y. Lin, glucose aided preparation of tungsten sulfide/multi-wall carbon nanotube hybrid and use as counter electrode in dye-sensitized solar cells. *ACS Appl. Mater. Interfaces*, 2012, 4, 6530–6536. Copyright© American Chemical Society.

of MWCNTs-WS₂ CEs having 1, 3, 7, and 10 wt% contents of MWCNTs were 4.54, 3.47, 3.24, and 4.59 $\Omega\text{ cm}^2$, respectively. The R_{CT} of the MWCNTs-WS₂ CE with 5 wt% contents of MWCNTs shows 2.53 $\Omega\text{ cm}^2$, comparable to the R_{CT} of 2.74 $\Omega\text{ cm}^2$ for a Pt CE. The DSSCs based on WS₂/MWCNTs CEs showed a PCE of 6.41% for 5 wt% MWCNTs, comparable to the PCE of 6.56% for Pt CE under a simulated AM 1.5 solar illumination (100 mW cm^{-2}). The low R_{CT} of WS₂/MWCNTs CEs at the electrolyte/electrode interface contributed to the higher PCEs.

The WS₂ based CEs prepared by a hydrothermal method was also used for DSSC by Wu *et al.*,¹⁴¹ which exhibited a PCE of 7.73%. The same research team¹⁸⁶ also synthesized WS₂/MWCNTs hybrids by a glucose-aided (G-A) hydrothermal route, which is discussed here in detail. Fig. 11 presents the SEM images of WS₂, MWCNTs, and (G-A)WS₂/MWCNTs composites, and J - V curves of the DSSCs with WS₂, MWCNTs, WS₂/MWCNTs* (prepared without the aid of glucose), WS₂/MWCNTs, and Pt CEs, under a simulated solar illumination of 100 mW cm^{-2} . The WS₂ exhibits graphene-like lamellar structure, whereas the MWCNTs have a fiber-like structure, indicating both materials have a large specific surface area. The specific surface area of the (G-A)WS₂/MWCNTs composite was estimated to be 230 $\text{m}^2\text{ g}^{-1}$ by the Brunauer-Emmett-Teller (BET) technique, indicating high electrochemical activity as well as photovoltaic efficiency for CEs. The cathodic peak potentials of the WS₂, WS₂/MWCNTs, and WS₂/MWCNTs* CEs showed cathodic peak potentials of -0.14, -0.13 and -0.17 V, respectively, which implies that the MWCNTs help in improving the electrocatalytic activity, and a lower cathodic peak potential observed for (G-A)WS₂/MWCNTs as opposed to WS₂/MWCNTs* results from the large specific surface area generated by glucose aided preparation. The EIS measurements yielded an R_{CT} of 2.49 $\Omega\text{ cm}^2$ and R_s of 2.54 $\Omega\text{ cm}^2$ for the WS₂/MWCNTs hybrid CE, which is smaller compared with WS₂ CE, and indicates the synergistic effect between WS₂ and MWCNTs that enhanced the electrical conductivity of the hybrid. The (G-A)WS₂/MWCNT CE based DSSC resulted in a PCE of 7.36%, comparable to WS₂ CE (5.32%), MWCNTs CE (4.34%), and the Pt CE (7.54%). The J_{sc} and PCE values increased with increasing content of MWCNTs, up to 5 wt% in the WS₂/MWCNT hybrid CEs, and thereafter started decreasing with further increases in MWCNTs content. The (G-A)WS₂/MWCNT (5 wt%) film also exhibits a smaller transmission between 320 to 800 nm than Pt film, therefore the WS₂/MWCNT film absorbs more incident light, which also further improves photovoltaic performance. The glucose aided (G-A)WS₂/MWCNTs (5 wt%) CE in the DSSC had low R_{CT} and high electrocatalytic activity for the reduction of triiodide (I_3^-), due to the synergistic effects induced by glucose.

3.3 TiS₂ counter electrodes

Titanium disulfide (TiS₂) is a metallic thermoelectric material which attains unique morphologies such as nanotubes, nanoclusters and nanodisks, and exhibits interesting physical properties.^{187–198} Meng *et al.*¹⁹⁹ has prepared 2D TiS₂ nanosheets decorated on graphene using a ball milling method and followed by high-temperature annealing. The electroactive surface

Fig. 12 A comparison of photocurrent density-voltage (J - V) curves of DSSCs having TiS₂-graphene hybrid and Pt counter electrodes. Reprinted with permission from ref. 199, X. Meng, C. Yu, B. Lu, J. Yang and J. Qiu, dual integration system endowing two-dimensional titanium disulfide with enhanced triiodide reduction performance in dye-sensitized solar cells. *Nano Energy*, 2016, 22, 59–69. Copyright© Elsevier.

areas of 1.70 cm^2 for TiS₂-graphene and 0.232 cm^2 for Pt electrodes, measured by CV, indicate more active sites for the hybrid. Fig. 12 compares J - V curves of DSSCs having TiS₂-graphene and Pt/FTO CEs. The CEs based on TiS₂-graphene hybrids exhibited higher electrocatalytic activity for the reduction of triiodide (I_3^-) to iodide (I^-) in electrolyte with a PCE of 8.80%, which is higher than the Pt CE ($\eta = 8.00\%$). The R_s of TiS₂-graphene CEs (2.32 $\Omega\text{ cm}^2$) was found to be smaller compared to the Pt CEs (6.90 $\Omega\text{ cm}^2$), showing better contact between the hybrid CE and FTO glass. Furthermore, the R_{CT} of TiS₂-graphene CE (0.63 $\Omega\text{ cm}^2$) was also lower than the Pt CE (1.32 $\Omega\text{ cm}^2$), which again indicates a higher electrocatalytic activity for the reduction of triiodide (I_3^-). Also, the Z_N of TiS₂-graphene CE (10.52 $\Omega\text{ cm}^2$) was found to be higher than the Pt CE (6.89 $\Omega\text{ cm}^2$). The high electrocatalytic activity of the TiS₂-graphene hybrids is attributed to the highly electroactivity of TiS₂ and enhanced transport facilitated by the graphene conductive network.

Li *et al.*²⁰⁰ deposited composite films of TiS₂/PEDOT:PSS on ITO substrates by drop coating, to study CEs of DSSCs. The wt% of TiS₂ particles in TiS₂/PEDOT:PSS composite films varied from 5 to 15 wt%. TiS₂ particles were dispersed in a PEDOT:PSS matrix to be used as an electrocatalyst for the I^-/I_3^- redox reaction. In the composite, conducting polymer PEDOT:PSS plays the role of a binder for the TiS₂ nanoparticles, as well as a linking agent between TiS₂ particles and the ITO substrate, and also facilitates electron transfer. The TiO₂ photoanode for a DSSC was prepared by immersing it in N719 dye solution for 24 hours at room temperature. Fig. 13 shows the photocurrent density-voltage curves and IPCE curves of the DSSCs with Pt, bare TiS₂, bare PEDOT:PSS, and 10 wt% TiS₂/PEDOT:PSS composite CEs. The TiS₂/PEDOT:PSS composite CE offered a large surface area, yielding a high PCE of 7.04%. The CEs of bare TiS₂, bare PEDOT:PSS, the TiS₂/PEDOT:PSS composite, and Pt were characterized by AFM, SEM, and EDX. AFM images indicated a roughness of 45 nm for PEDOT:PSS and of 378 nm for TiS₂/PEDOT:PSS composite film; therefore, the higher

Fig. 13 (a) Photocurrent density–voltage curves of DSSCs with Pt, bare TiS₂, bare PEDOT:PSS, and 10 wt% TiS₂/PEDOT:PSS composite based CEs recorded under light illumination of 100 mW cm⁻² (AM 1.5). (b) Incident photon-to-current conversion efficiency (IPCE) curves of the DSSCs with similar CEs. Reprinted with permission from ref. 200, C. T. Li, C. P. Lee, Y. Y. Li, M. H. Yeh and K. C. Ho, a composite film of TiS₂/PEDOT:PSS as the electrocatalyst for the counter electrode in dye-sensitized solar cells. *J. Mater. Chem. A*, 2013, **1**, 14888–14896. Copyright© Royal Society of Chemistry.

roughness could lead to a larger active surface area and consequently to the higher electrocatalytic activity for the TiS₂/PEDOT:PSS composite thin. The electrocatalytic properties of the DSSCs using the CEs of bare TiS₂, bare PEDOT:PSS, the TiS₂/PEDOT:PSS composite, and Pt were evaluated by CV, RDE, EIS, and Tafel polarization measurements. The high PCE of the TiS₂/PEDOT:PSS composite CE based DSSC was also measured by IPCE curves. The maximum of the IPCE spectra at 520 nm increased from 52% to 63% as the content of TiS₂ particles increased from 0 to 10 wt%, respectively, and similar characteristics were observed for the J_{sc} values from the J - V curves of the DSSCs. The 10 wt% TiS₂/PEDOT:PSS composite film based CE shows a higher redox current density compared with bare TiS₂ and PEDOT:PSS CEs, therefore, it possesses high

electrocatalytic activity for triiodide (I₃⁻) reduction, and it also exhibits high electrochemical stability after 100 consecutive cycles in the I⁻/I₃⁻ redox electrolyte.

3.4 NiS₂ counter electrodes

Nickel disulfide (NiS₂) is a semiconducting material with pyrite structure which acquires unique morphologies such as hollow prisms, nano/microspheres, nanocubes, nanosheets, nanoparticles, and also exhibits interesting electrical, optical, magnetic, and catalytic properties.^{201–205} Depending upon the synthesis procedures, the stoichiometric composition of nickel sulfide varies to a great extent (NiS, NiS₂, Ni₃S₂, Ni₃S₄, Ni₆S₅, Ni₇S₆, Ni₉S₈, etc.).

In one study, hierarchical NiS₂ hollow microspheres on a FTO substrate were prepared by a hydrothermal method to use as a CE for a DSSC.²⁰⁶ The NiS₂ hollow microspheres were partially broken, offering more active sites for electrocatalysis and electrolyte adsorptions. The IPCE values of 81.3% for the NiS₂ microspheres CE and 76.6% for the Pt CEs at 500 nm were observed. The peak current density of the NiS₂ microspheres CE was found to be higher than the Pt CE, whereas the peak-to-peak separation (E_{pp}) value was lower by 10 mV compared to Pt CE, which suggests a high electrocatalytic activity for the NiS₂ microspheres CE in the reduction of triiodide (I₃⁻) in the electrolyte. The NiS₂ hollow microspheres CE based DSSC showed a PCE of 7.84%, equal to the Pt CE (7.89%), indicating their potential as low-cost CEs for DSSCs. The NiS/NiS₂ composite hollow spheres prepared by a solvothermal method exhibited a low R_{CT} of 0.34 Ω cm⁻² at the CE/electrolyte interface, and a PCE of 7.66%, outperforming the Pt CE (7.01%), and showed high electrocatalytic activity for I₃⁻ reduction, and also better electrochemical stability.²⁰⁷ The NiS and NiS₂ hollow spheres were synthesized through a solvothermal process.²⁰⁸ The Ni/S molar ratio controlled the different stoichiometric ratios of nickel sulfides. The NiS₂ CE based DSSC showed a higher electrocatalytic activity than that of the NiS CE for I₃⁻ reduction. The DSSC with NiS₂ CE yielded a PCE value of 7.13% in comparison to 6.49% for NiS CE.

NiS₂ polyhedrons were studied as CEs for DSSCs by Zheng *et al.*²⁰⁹ Fig. 14 shows SEM, TEM, and selected area electron diffraction (SAED) images of NiS₂ octahedrons and NiS₂ cubes, and electrochemical characteristics of DSSCs having NiS₂ octahedrons, NiS₂ cubes and Pt CEs, under simulated AM1.5G solar light. The average size of NiS₂ octahedrons and cubes were about 250 nm. The electrochemical performance of NiS₂ octahedron and cube based CEs were evaluated using CV, J - V characteristics, EIS, and the Tafel polarization method. The NiS₂ octahedron CEs showed peak current density of 1.40 mA cm⁻², compared to 1.22 mA cm⁻² for the NiS₂ cubes, indicating better electrocatalytic activity. The NiS₂ octahedron CEs also exhibited a higher J_{sc} of 13.55 mA cm⁻² and FF of 62%, higher than that of the NiS₂ cube CE (J_{sc} of 12.62 mA cm⁻² and FF of 60%), giving rise to a higher PCE. Octahedral NiS₂ nanocrystals based CEs incorporated into DSSCs exhibited a PCE of 5.98%, slightly higher than that of the NiS₂ cube nanocrystals (η = 5.43%). The NiS₂ octahedron CE had a PCE of up to 91% of the

Fig. 14 SEM, TEM, and SAED images of NiS₂ octahedrons (a–c) and NiS₂ cubes (d–f). SAED patterns of NiS₂ octahedrons (c) and NiS₂ cubes (f) were recorded from the corresponding particles depicted (b) and (e), respectively. (g) C–V curves of DSSCs having counter electrodes of NiS₂ octahedrons, NiS₂ cubes and Pt for the reduction of tri-iodide (h) J–V curves of DSSCs with NiS₂ octahedrons, NiS₂ cubes and Pt CEs under simulated AM1.5G solar light. Nyquist plots (i) and Tafel polarization curves (j) of DSSCs having NiS₂ octahedrons, NiS₂ cubes and Pt CEs. Reprinted with permission from ref. 209, J. Zheng, W. Zhou, Y. Ma, W. Cao, C. Wang and L. Guo, facet-dependent NiS₂ polyhedrons on counter electrodes for dye-sensitized solar cells. *Chem. Commun.*, 2015, 51, 12863–12866. Copyright© Royal Society of Chemistry.

conventional Pt CE in DSSCs ($\eta = 6.55\%$). The R_s of the NiS₂ octahedron based CE was $13.14 \Omega \text{ cm}^2$, somewhat lower than that of the NiS₂ cube CE (R_s of $14.98 \Omega \text{ cm}^2$), indicating higher

electrical conductivity of the NiS₂ octahedron based CE. The R_{CT} of the NiS₂ octahedron CE was measured as $9.86 \Omega \text{ cm}^2$, also lower than that of the NiS₂ cube CE (R_{CT} of $13.17 \Omega \text{ cm}^2$), which

Fig. 15 (a) Photocurrent density–voltage (J – V) curves of DSSCs with bare NiS_2 , NiS_2 @RGO nanocomposites, bare RGO, and Pt CEs measured under light illumination of 100 mW cm^{-2} (AM 1.5). Reprinted with permission from ref. 210, Z. Li, F. Gong, G. Zhou and Z. S. Wang, NiS_2 /reduced graphene oxide nanocomposites for efficient dye-sensitized solar cells. *J. Phys. Chem. C*, 2013, **117**, 6561–6566. Copyright© American Chemical Society.

demonstrates that the NiS_2 octahedrons with $\{111\}$ facets possesses better electrocatalytic activity than the NiS_2 cubes with $\{100\}$ facets.

The electrocatalytic performance of NiS_2 nanoparticles and their nanocomposites with RGO were compared by Li *et al.*²¹⁰ In a hydrothermal process, graphene oxide was transformed to RGO, and then NiS_2 @RGO nanocomposites were formed by depositing NiS_2 nanoparticles on the surface of RGO. CEs for DSSCs were fabricated by drop-casting solutions of NiS_2 , NiS_2 @RGO, and RGO nanocomposites on FTO-coated glass substrate. The surface areas measured by the BET method were 11.4 , 9.4 , and 8.6 , and $5.8 \text{ m}^2 \text{ g}^{-1}$ for NiS_2 @RGO, NiS_2 , and RGO, respectively. Fig. 15 shows J – V curves of DSSCs with bare NiS_2 , NiS_2 @RGO nanocomposites, bare RGO, and Pt CEs. The NiS_2 @RGO nanocomposites based CE showed a PCE of 8.55% ($J_{\text{sc}} = 16.55 \text{ mA cm}^{-2}$, $V_{\text{oc}} = 0.749 \text{ V}$, and $\text{FF} = 0.69$), much higher than that of the NiS_2 CE ($\eta = 7.02\%$), RGO CE ($\eta = 3.14\%$), or standard Pt CE ($\eta = 8.15\%$) for the DSSCs under the same experimental conditions. The larger R_{CT} values of $100.2 \Omega \text{ cm}^2$ for RGO and $8.8 \Omega \text{ cm}^2$ for NiS_2 also suggest the low electrocatalytic activity. On the other hand, the smaller R_{CT} value of $2.9 \Omega \text{ cm}^2$ for the NiS_2 @RGO nanocomposite indicates much higher electrocatalytic activity for the reduction of triiodide (I_3^-) in electrolyte due the cooperative synergetic effect and the increased conductivity from the RGO nanosheets. This study demonstrates that NiS_2 @RGO nanocomposites are a promising alternate CE to conventional Pt CE for DSSC devices.

3.5 FeS_2 based counter electrodes

Pyrite iron disulfide (NiS_2) acquires unique morphological structures including nanocrystals, nanowires, nanosheets, nanocubes, and exhibits interesting electrical, photovoltaic, and catalytic properties.^{211–220} An interesting comparative study was done by Shukla *et al.*²²¹ on pyrite iron disulfide (FeS_2) as a CE material in comparison with Pt and PEDOT CEs in DSSCs.

The FeS_2 film CEs were fabricated on a FTO glass substrate by a spray pyrolysis method and used in I_3^-/I^- and $\text{Co(III)}/\text{Co(II)}$ electrolyte-mediated DSSCs. N719 dye was used for the DSSC with I_3^-/I^- redox electrolyte and C128 dye for the $[\text{Co}(\text{bpy})_3]^{2+/3+}$ redox electrolyte. The I_3^-/I^- redox electrolyte contained 1.0 mM of 1,3-dimethylimidazolium iodide, 50 mM of LiI , 30 mM of I_2 , 0.5 mM of *tert*-butylpyridine, and 0.1 mM of guanidinium thiocyanate in a acetonitrile and valeronitrile (v/v, 85/15) mixed solution. The cobalt electrolyte was made up of 0.22 M of $\text{Co}(\text{bpy})_3(\text{TFSI})_2$, ($\text{bpy} = 2,2'$ -bipyridine and $\text{TFSI} = [\text{bis}(\text{trifluoromethane})\text{-sulfonimide}]$), 0.05 M of $\text{Co}(\text{bpy})_3(\text{TFSI})_3$, 0.1 M of lithium *bis*(trifluoromethanesulfonyl)imide (LiTFSI), and 0.2 M of *tert*-butylpyridine (*tBP*) in acetonitrile. Fig. 16 shows the J – V curves and IPCE of the DSSCs with FeS_2 and Pt CEs in I_3^-/I^- electrolyte, and DSSCs with FeS_2 and PEDOT CEs in the $\text{Co(III)}/\text{Co(II)}$ electrolyte. The catalytic activity of the FeS_2 film CEs was found to be comparable to the Pt and PEDOT CEs, which were both in I_3^-/I^- and $\text{Co}^{2+}/\text{Co}^{3+}$ electrolytes, respectively. With the I_3^-/I^- electrolyte, a PCE of 7.97% was observed for the FeS_2 film CE and a PCE of 7.54% for the Pt CE in the I_3^-/I^- electrolyte, whereas the PCEs were almost the same (6.3%) for the FeS_2 film and PEDOT CEs in the $[\text{Co}(\text{bpy})_3]^{2+/3+}$ redox-mediated DSSCs. The performance of the DSSCs with FeS_2 and Pt CEs was studied by varying solar light illumination intensities between 1 Sun and 0.1 Sun. The current density was observed to be higher for the FeS_2 CE (15.20 mA cm^{-2}) than for the Pt CE (14.77 mA cm^{-2}) at 1 Sun light intensity. When the solar light intensity was reduced to 0.5 and 0.1 Sun, the difference in current density between the FeS_2 and Pt CEs was not noticeable, with the J_{sc} values being 8.97 and 8.91 mA cm^{-2} at 0.5 Sun, and 1.75 and 1.74 mA cm^{-2} at 0.1 Sun for the Fe and Pt CEs, respectively. The PCE values for the FeS_2 and Pt CEs were 9.27% and 8.92% at 0.5 Sun, and 8.68% and 8.32% at 0.1 Sun, respectively. The excellent performance of FeS_2 film in both electrolyte systems makes it very interesting for applications in DSSCs.

In an interesting study, FeS_2 nanorod arrays were fabricated on a FTO substrate after sulfurizing $\text{FeO}(\text{OH})$ nanorods, and used as a CE for DSSCs.²²² The FeS_2 nanorods exhibited better electrocatalytic activity than FeS_2 films and Pt-based CEs due to more active sites, which resulted in high J_{sc} value of the DSSCs. The FeS_2 nanorods-based CEs showed lower interface resistance compared with FeS_2 thin films, which leads to a higher FF and hence a higher PCE comparable to Pt CE based DSSCs. The electrochemical stability of the FeS_2 nanorod arrays-based CE measured in I_3^-/I^- electrolyte showed a slight change in CV plots up to 10 consecutive days of aging time. In another study, FeS_2 powder prepared through a hydrothermal method was used as a CE for fabricating DSSCs.²²³ The effect of NaOH addition on FeS_2 crystal size and electrocatalytic activities was then studied. It was observed that the size of FeS_2 nanoparticles decreased after adding NaOH, and the resulting photovoltaic performance and electrocatalytic activity of DSSC with FeS_2 powder significantly increased, achieving a PCE of 5.78% under simulated sunlight irradiation of 1 Sun.

A chemically prepared FeS_2 nanocrystal ink was used to fabricate a CE for a DSSC, which showed a PCE of 7.31% after

Fig. 16 (a) Photocurrent density–voltage (J – V) curves and (b) IPCE of the DSSCs with FeS_2 and Pt counter electrodes using N719 dye in I_3^-/I^- electrolyte. (c) J – V curve and (d) IPCE of the DSSCs with FeS_2 and PEDOT counter electrodes using C128 dye in Co^{3+}/Co^{2+} electrolyte. Reprinted with permission from ref. 221, S. Shukla, N. H. Loc, P. P. Boix, T. M. Koh, R. R. Prabhakar, H. K. Mulmudi, J. Zhang, S. Chen, C. F. Ng, C. H. A. Huan and N. Mathews, iron pyrite thin film counter electrodes for dye-sensitized solar cells: high efficiency for iodine and cobalt redox electrolyte cells. *ACS Nano*, 2014, 8, 10597–10605. ethanedithiol (EDT) treatment.²²⁴ FeS_2 nanocrystal ink casted on a flexible ITO/PET substrate exhibited a J_{sc} of 14.93 mA cm^{-2} , V_{oc} of 0.71 V, FF of 0.60, and a PCE of 6.36%. The semi-transparent FeS_2 nanocrystal/ITO glass CE has an optical transmittance of 50–70% between 300 to 800 nm in comparison to 15% transmittance for the reference Pt/ITO glass CE. When the DSSC with the FeS_2 nanocrystal CE was illuminated from the rear side, it showed a PCE of 4.17%, which was 57% of the front illumination value, whereas opaque Pt CE had a PCE of 1.06% from the rear side. Semi-transparent FeS_2 nanocrystal CEs offer bifacial DSSCs utilizing incident light from both front and rear sides, and thus could be cost-effective for energy production. The FeS_2 nanocrystal ink also demonstrated high electrocatalytic activity and electrochemical stability. Additionally, MWCNT/ TiO_2 hybrid and pure TiO_2 mesoporous photoanodes with FeS_2 thin films as CEs were studied for DSSCs by Kilic *et al.*²²⁵ In the MWCNT/ TiO_2 hybrid photoanode, CNT played an important role of increasing the optical absorption and shifting it toward a longer wavelength region, where the bandgap of 3.15 eV for mesoporous TiO_2 shifted to 2.5 eV for the MWCNT/ TiO_2 hybrid. The DSSC with the MWCNT/ TiO_2 hybrid photoanode and the Pt CE showed values of J_{sc} of 15.96 mA cm^{-2} , V_{oc} of 0.77 V, FF of 0.57 and a PCE of 7.0%. The DSSC with the pure mesoporous TiO_2 photoanode and the Pt CE both resulted in

PCEs of 6.51%. The enhancement in PCE value of the hybrid photoanode is associated with MWCNTs, which offer an electrical conduction pathway for speedy electron transport. The MWCNT/ TiO_2 hybrid photoanode also showed an increase in IPCE in the 350–600 nm wavelength range compared to the mesoporous TiO_2 photoanode. When FeS_2 thin films were used as a CE with a MWCNT/ TiO_2 hybrid photoanode, the PCE of the DSSC increased to 7.27% under 1 Sun. The DSSC with a FeS_2 CE and a pure TiO_2 photoanode both yielded a PCE of 6.65%. The FeS_2 thin films showed an optical bandgap of 1.27 eV and large effective surface area, which contribute to more light absorption and increased electrocatalytic activity for the reduction of triiodide (I_3^-).

3.6 CoS_2 counter electrodes

Cobalt disulfide (CoS_2) is a semiconducting material that exhibits interesting magnetic, electrical, and catalytic properties for energy storage applications.^{226–231} The properties of CoS_2 nanocrystalline thin films prepared by a hydrothermal method were reported by Jin *et al.*²³² CoS_2 powder was dispersed in ethanol in order to prepare a nanoink (40 mg mL^{-1}) for fabricating a CE. The CoS_2 nanoink ($10\text{ }\mu\text{L}$) was drop-cast on an FTO glass or flexible ITO/PET substrate, followed by ethanol

evaporation. The self-assembled CoS₂ film CE has a thickness of 2.5 μm which can be controlled by the nanoink content. DSSCs were assembled by using a N719 dye-sensitized TiO₂ photoanode as the working electrode, a CoS₂ nanocrystal film or a Pt as the CE, and an electrolyte solution containing LiI (0.1 M), I₂ (0.05 M), 1,2-dimethyl-3-*n*-propylimidazolium iodide (DMPH, 0.6 M), and 4-*tert*-butylpyridine (TBP, 0.5 M) in acetonitrile. The morphology and structure of the CoS₂ self-assemblies were studied by SEM and TEM techniques. Fig. 17 shows an SEM image of a self-assembled CoS₂ nanocrystal film, a photographic image of CoS₂ nanoink, a self-assembled CoS₂ CE, and *J*-*V* curves of the DSSCs, fabricated with the CoS₂ nanocrystal thin film and a Pt CE on the FTO and flexible ITO/polyethylene terephthalate (PET) substrate. The CoS₂ nanoparticles were stabilized with poly(vinylpyrrolidone) (PVP) to form an oriented structure. The DSSC with self-assembled CoS₂ CE shows a *J*_{sc} of 14.62 mA cm⁻², *V*_{oc} of 0.71 V, and a FF of 0.64, resulting in a PCE of 6.78%, which is comparable to a Pt CE with a value of 7.38%. The PCE was found to decrease when the thickness of the self-assembled CoS₂ film was either higher or lower than 2.5 μm. The CoS₂ shows a *R*_s value of 34.20 Ω cm², slightly higher compared to Pt (27.13 Ω cm²), indicating comparable electrical conductivity. The *R*_{CT} value of 7.21 Ω cm² for the CoS₂ CE indicates higher electrocatalytic activity for the reduction of triiodide (I₃⁻). The CoS₂ CE has a high chemical capacitance (*C*_μ) of 27.57 μF, compared to 2.76 μF for the Pt CE, which also is evidence of a high surface area for CoS₂ CE which is beneficial to electrocatalysis. The DSSCs with CoS₂ deposited on a flexible ITO/PET substrate showed a *J*_{sc} of 13.17 mA cm⁻², *V*_{oc} of 0.70 V,

FF of 0.68 and a PCE of 6.40%. The fabrication of a CoS₂ CE is low-cost and solution processable at room temperature, which could make it an alternative to Pt CEs for flexible DSSCs.

Another study used mesoporous CoS₂ nanotube arrays deposited on an FTO glass substrate and used as a CE for a DSSC.²³³ The CoS₂ nanotube arrays were characterized by SEM, TEM, and XRD techniques for their morphology and crystal structures. The electrocatalytic properties of the CoS₂ nanotube arrays were measured using CV and Tafel polarization curve measurements. The DSSCs having CoS₂ CEs achieved a PCE of 6.13%, comparable to that of sputtered Pt CE (6.04%). The *R*_{CT} of the mesoporous CoS₂ nanotube array CE was found to be 3.51 Ω cm² and comparable to the Pt CE (5.78 Ω cm²). The CoS₂ nanotube array based CEs have large active surface area due to the mesoporous nanotube structure. The CoS₂ nanotube array CE also exhibits electrocatalytic activities comparable to Pt CE. Tsai *et al.*²³⁴ also prepared CoS₂ nanoflake arrays from Co(OH)₂ nanoflake arrays through an ion exchange reaction to develop CEs for DSSCs. The CoS₂ nanoflakes were found to be composed of CoS₂ single crystals as well as their aggregates. The DSSC with CoS₂ nanoflake arrays as a CE showed a PCE of 5.20%, comparable to a sputtered Pt CE (5.34%).

Different types of cobalt sulfide (CoS) have been used as CEs for DSSCs. The CoS nanoparticles deposited onto FTO glass substrates showed good transparency and high electrocatalytic activity for the I⁻/I₃⁻ redox couple for a DSSC.²³⁵ CoS nanoparticle CEs showed a low *R*_{CT} value of 1.3 Ω cm², less than that of Pt on FTO glass (*R*_{CT} of 2.3 Ω cm²) and achieved a PCE of 6.6%. An optimized CoS nanoparticle CE was also studied for

Fig. 17 (a) SEM image of a self-assembled CoS₂ nanocrystal film on FTO glass substrate, (b) cross-sectional SEM image of the CoS₂ counter electrode (CE), (c) photographic image of CoS₂ nanoink, and (d) self-assembled CoS₂ CE. (e) Photocurrent density–voltage (*J*-*V*) curves of the DSSCs with CoS₂ nanocrystal thin film and Pt CEs. (f) *J*-*V* curves of the DSSCs with CoS₂ deposited on a flexible ITO/PET substrate. (Right) photocurrent density–photovoltage (J – V) curves for DSSCs having Pt, RGO, SnS₂, and SnS₂@RGO composite CEs. Reprinted with permission from ref. 250, B. Yang, X. Zuo, P. Chen, L. Zhou, X. Yang, H. Zhang, G. Li, M. Wu, Y. Ma, S. Jin and X. Chen, nanocomposite of tin sulfide nanoparticles with reduced graphene oxide in high-efficiency dye-sensitized solar cells. *ACS Appl. Mater. Interfaces*, 2015, 7, 137–143. Copyright© American Chemical Society.

a ferrocene-based liquid electrolyte. The rose-petal like CoS₂ was deposited on an FTO as CE using a chemical bath deposition method.²³⁶ The DSSC assembled with a CoS₂ CE achieved a PCE of 5.32%, higher than that of a Pt CE (5.02%). The PCEs of CoS₂ CEs depend on the deposition parameters including the concentrations of urea and thioacetamide, and the deposition time of the CEs. Also, CoS₂ embedded carbon nanocages were fabricated as CEs for DSSCs through a zeolitic imidazolate framework-67, Co(2-methylimidazole)₂ template.²³⁷ The performance of the CoS₂ CE in a DSSC was optimized *via* a sulfurization process, where CoS₂ nanoparticles with embedded carbon nanocages were sulfurized for a period of 4 hours, and showed the highest PCE of 8.20%, even higher than Pt-based CE (7.88%). The synergic effect of CoS₂ nanoparticles and the carbon matrix resulted in the CE having high electrical conductivity and catalytic activity. Kim *et al.*²³⁸ deposited CoS₂, nickel sulfide (NiS), and Ni-doped CoS₂ nanoparticles on a FTO substrate as CEs for DSSCs *via* a chemical bath deposition method. The surface morphology of the thin films was analyzed by SEM. Electrochemical properties of Ni-doped CoS₂ thin films evaluated by EIS, CV, and Tafel polarization curves indicated increased electrocatalytic activity for the reduction of I₃[−] in the DSSCs compared to Pt CEs. The Ni-doped CoS₂ CE (15% Ni) showed a PCE of 5.50% under 1 Sun illumination, exceeding the PCE of the Pt CE (η = 5.21%). PCE and R_{CT} values of the DSSCs were found to depend on the amount of Ni-doping of the CoS₂ nanoparticles. These yielded PCEs of 4.81, 5.17, 5.50, and 4.12%, for R_{CT} values of 279.7, 36.63, 8.53 and 82.72 Ω cm², at 5, 10, 15 and 20% Ni contents in the CoS₂ CE, respectively. Comparatively, DSSCs with bare CoS₂ and NiS CEs showed poor electrocatalytic activity of I₃[−] reduction.

In another study, CoS₂/graphene composites were prepared *via* a hydrothermal method using Co ions with thiourea in the presence of graphene oxide (GO).²³⁹ The distribution and size of the CoS₂ nanoparticles deposited onto a flexible graphene sheet was controlled in order to optimize the electrocatalytic activity for I₃[−] reduction. A CoS₂ nanoparticles/graphene sheet (CoS₂/G₅₀) CE was prepared by incorporating 50 mg graphene oxide,

and exhibited the lowest electrolyte diffusion resistance and the highest electrocatalytic activity. The DSSC with CoS₂/G₅₀ CE achieved a PCE of 6.55%, higher than bare CoS₂ or graphene CEs or a conventional Pt CE (η = 6.20%). Also, CoS₂/RGO composite films for a CE of a DSSC were prepared using the layer-by-layer (LbL) assembly method, followed by thermal annealing.²⁴⁰ The photovoltaic parameters of the CoS₂/RGO CE based DSSCs were found to depend upon the deposition times of graphene oxide. PCE values of 2.6, 4.1, 5.4, 2.9 and 1.4% were measured for 2, 4, 6, 8 and 10 deposition times of graphene oxide, respectively. It appeared that the lowest R_{CT} of 4.8 Ω cm² was observed for a CoS₂/RGO CE prepared with 6 deposition times.

3.7 SnS₂ counter electrodes

Tin disulfide (SnS₂) attains morphological structures which include nanocrystals, nanosheets, nanowires, nanobelts, and these show potential for field-effect transistors, gas sensors, photocatalysts, and solar cells.^{241–248} In one study, semi-transparent SnS₂ nanosheets were prepared as a CE to develop a Pt-free DSSC for the reduction of I₃[−].²⁴⁹ The SnS₂-based CE with 300 nm thickness showed high electrocatalytic activity, with a PCE of 7.64% compared to a PCE of 7.71% for a Pt CE based DSSC. When SnS₂ nanosheets were functionalized with carbon nanoparticles, the CE exhibited a PCE of 8.06%, a better electrocatalytic performance than a Pt CE. SnS₂ nanosheets could therefore be used as a low cost electrocatalytic electrode material for DSSCs. Yang *et al.*²⁵⁰ prepared SnS₂ nanoparticles and a RGO nanocomposite as a Pt-free CE for a DSSC. The SnS₂ nanoparticles dispersed onto RGO sheets exhibited improved electrocatalytic activity for reducing I₃[−], and also increased conductivity. Fig. 18 illustrates the preparation of SnS₂@RGO nanocomposites and compares J – V curves for DSSCs having Pt, RGO, SnS₂, and SnS₂@RGO composite CEs. The DSSC with SnS₂@RGO nanocomposite CE showed a PCE of 7.12%, much higher than that of the RGO sheet alone (3.73%) and SnS₂ nanoparticles (5.58%), and a comparable PCE value to Pt CE (6.79%). The Z_N values were 0.64, 4.36, 5.01 and 0.95 Ω for the

Table 3 Photovoltaic parameters of WS₂, NiS₂, TiS₂, FeS₂, CoS₂, and SnS₂ based CEs used in DSSCs. FTO glass is the common substrate used in assembling DSSCs with different CE materials. The measurements were conducted at a simulated solar light intensity of 100 mW cm⁻² (AM 1.5G) unless specified. The photovoltaic parameters short-circuit photocurrent density (J_{sc}), open-circuit voltage (V_{oc}), fill factor (FF), and power conversion efficiency (η), series resistance (R_s), charge-transfer resistance (R_{CT}), electrolyte and dye used for DSSCs are summarized and compared with standard Pt counter electrode^a

^a WS₂/MWCNTs* prepared without glucose aid. In the case of R_s and R_{CT} : some of the authors used Ω instead of Ω cm² for the resistances without mentioning the size of the electrode.

SnS₂@RGO nanocomposite, SnS₂, RGO and Pt CEs, respectively. The RGO and SnS₂ CEs have larger R_{CT} values, hence lower electrocatalytic ability among these CEs, whereas the SnS₂@RGO composite has a lower R_{CT} value, leading to a higher electrocatalytic activity. The role of the RGO sheets is to facilitate the conduction pathway. The E_{pp} of the SnS₂@RGO nanocomposite CE is 593 mV, similar to a Pt CE (E_{pp} of 605 mV). This indicates that the electrocatalytic activity of the SnS₂@RGO nanocomposite CE is similar to that of a conventional Pt CE. The electrochemical stability of the SnS₂@RGO nanocomposite CE was analyzed up to 25 cycles of CV curves, where no drastic change was noticed in peak current density, confirming that SnS₂@RGO nanocomposite CEs are stable for electrocatalysis of I₃⁻ in the electrolyte. The SnS₂@RGO nanocomposite CEs are as promising as Pt CEs in DSSCs. Table 3 lists a summary of the photovoltaic parameters of WS₂, NiS₂, TiS₂, FeS₂, CoS₂, and SnS₂ based CEs for DSSCs and their comparison with a standard Pt CE.

4. Transition-metal diselenides based counter electrodes

4.1 MoSe₂ counter electrodes

Molybdenum dichalcogenides, such as MoS₂, MoSe₂, and MoTe₂, are a very interesting class of materials that has attracted a great attention because of their unique properties.^{251–257} Molybdenum diselenide (MoSe₂) is a semiconductor that has been studied for device applications.^{92,258,259} The nanosheets of MoSe₂ have weak van der Waals forces, therefore, poorly adhere to the surface of substrates. To resolve this problem, Lee *et al.*²⁶⁰ and Chen *et al.*²⁶¹ applied a CVD technique to grow catalytic MoSe₂ films on Mo foils. Lee *et al.*²⁶⁰ used few-layer MoSe₂ in a DSSC as CE for the reduction of I₃⁻ to I⁻. Fig. 19 shows a schematic representation for the preparation of few-layer MoSe₂, and their SEM and TEM images. The few-layer MoSe₂ on Mo film was developed by selenizing the Mo-coated soda-lime glass in a tube furnace. X-ray diffraction analysis exhibits

Fig. 19 (a) Schematic representation for the selenization of Mo-coated soda-lime glass in a tube furnace for few-layer MoSe₂; (b) schematic illustration showing the formation of few-layer MoSe₂ from body-centered cubic (bcc) crystal structures of Mo (c) cross-sectional SEM image of the MoSe₂ on Mo surface, inset shows the borderline between MoSe₂ and Mo substrate; (d) SEM image of the as-synthesized MoSe₂ nanostructures; (e) HRTEM image of the few-layer MoSe₂; (f) high magnification HRTEM image of the few-layer MoSe₂ with interlayer spacing of 0.63–0.64 nm. Reprinted with permission from ref. 260, L. T. L. Lee, J. He, B. Wang, Y. Ma, K. Y. Wong, Q. Li, X. Xiao and T. Chen, few-layer MoSe₂ possessing high catalytic activity towards iodide/tri-iodide redox shuttles. *Sci. Rep.*, 2014, 4, 4063–4069. Copyright© Nature Publishing Group.

body-centered cubic (bcc) crystal structures of the Mo film. The Mo film thickness was 1 μm and selenization was performed at 550 °C for 5 minutes, and produced the best performance for the DSSC. The MoSe₂ layer was about 70 nm as confirmed by the cross-sectional SEM image. The surface of the selenized Mo/glass contains nanoparticles, and the HRTEM image shows the few-layer structures. The interlayer spacing was measured as 0.63–0.64 nm. The few-layer MoSe₂ was prepared by surface selenization of Mo-coated soda-lime glass, which yielded a PCE of 9.0%, compared to a PCE of 8.68% for the Pt/FTO-based photoanode, thus showing the Pt/FTO free MoSe₂ CE outperformed the conventional CE. An MoSe₂/Mo combination as a CE in a DSSC shows a PCE of 8.69%. Fig. 20 shows a comparison of *J*–*V* curves of the DSSCs having MoSe₂/Mo and MoS₂/Mo CEs with different temperatures and times of selenization and sulfurization, and the Pt/FTO CE. The PCE of the DSSCs decreased from 7.14% for MoSe₂ CEs selenized at 580 °C

for 60 minutes, to a PCE of 4.26% for 120 minutes. The edge sites were also found to be important for the high catalytic activity. The Mo substrate plays an important role in significantly reducing the sheet resistance of the CE, which eventually leads to a high DSSC performance. The low sheet resistance of 0.29 Ω sq^{−1} for MoSe₂/Mo, compared to 12.60 Ω sq^{−1} for Pt/FTO, indicates that MoSe₂/Mo is better as a CE in a DSSC than a Pt/FTO. The *R*_{CT} of 0.87 Ω cm² for MoSe₂ and 0.61 Ω cm² for MoS₂ is lower compared to Pt (6.26 Ω cm²) due to high conductivity of the Mo substrate, therefore the Mo substrate seems superior to the FTO substrate. Chen *et al.*²⁶¹ also used a MoSe₂/Mo based CE in a DSSC to develop a Pt/FTO-free CE, which showed a PCE of 8.13%, slightly higher than the Pt/FTO CE (PCE of 8.06%). The *R*_s and *R*_{CT} values of the MoSe₂/Mo CEs were found to be 16.5% and 3.35% of the Pt/FTO CE, indicating a higher electrocatalytic activity of the MoSe₂/Mo.

Fig. 20 Photocurrent density–voltage (J – V) curves of DSSCs having MoSe_2/Mo and MoSe_2/Mo counter electrodes with different temperatures and time of selenization and sulfurization and a comparison with conventional Pt/FTO counter electrodes. Reprinted with permission from ref. 260, L. T. L. Lee, J. He, B. Wang, Y. Ma, K. Y. Wong, Q. Li, X. Xiao and T. Chen, few-layer MoSe_2 possessing high catalytic activity towards iodide/tri-iodide redox shuttles. *Sci. Rep.*, 2014, **4**, 4063–4069. Copyright© Nature Publishing Group.

Thin films of the metal selenides NiSe_2 , CoSe_2 , and MoSe_2 were used as CEs for DSSCs for I_3^- reduction by Ji *et al.*²⁶² NiSe_2 was found to be equally efficient to conventional Pt CEs. In comparison, NiSe_2 also showed a higher PCE than its sulfide analog (NiS_2) due to lower resistance to charge transfer. Fig. 21 shows SEM images of NiSe_2 , CoSe_2 , and MoSe_2 , and Tafel polarization curves and J – V curves of the metal selenides NiSe_2 , CoSe_2 , MoSe_2 , WSe_2 , Bi_2Se_3 , MnSe , PbSe , as well as Pt based CEs used in DSSCs. The metal selenides were deposited on FTO glass. The NiSe_2 , CoSe_2 , and MoSe_2 showed higher exchange current densities compared to other selenides. The J – V curve measurements of the DSSCs indicated better performance of the NiSe_2 CE than that of the Pt CE, however the performance of DSSCs having CoSe_2 and MoSe_2 CEs was lower compared to the Pt CE.

In another study, MoSe_2 nanosheets were prepared using a solvothermal method which shows microsphere hierarchical architecture.²⁶³ MoSe_2 nanosheets used as CE in fabricating a DSSC device showed a PCE of 9.80%, exceeding the PCE of a Pt CE based DSSC ($\eta = 8.17\%$) for the triiodide/iodide (I_3^-/I^-) redox reaction. Bi *et al.*²⁶⁴ anchored fullerene-structured MoSe_2 hollow spheres on highly nitrogen-doped graphene (HNG) as a CE for a DSSC. Diethylenetriamine (DETA) was used as a dopant for nitrogen of graphene. The hollow spheres consisted of 12–15 layers of MoSe_2 which formed the conductive network for facilitating rapid electron transfer in the DSSC. The MoSe_2 hollow spheres of 60–100 nm diameter and 8–12 nm thickness were dispersed on a HNG surface. The HNG– MoSe_2 hybrid has 52.4 wt% of MoSe_2 content. The N content increased from 2.5% in $\text{MoSe}_2/\text{graphene}$ hybrid to 12.5% in the HNG– MoSe_2 hybrid, which also showed high stability after 200 consecutive cycles of CV measurements. The HNG– MoSe_2

hybrid CE showed a PCE of 10.01%, slightly lower than a Pt CE ($\eta = 10.55\%$) under similar conditions, while the $\text{MoSe}_2/\text{graphene}$ hybrid CE had a PCE of 7.34% arising from a poor fill factor of 0.60.

Composites of MoSe_2 nanosheets (NS) and poly(3,4 ethylenedioxythiophene):poly(styrenesulfonate) were investigated as the CE of a DSSC by Huang *et al.*²⁶⁵ MoSe_2 NS acts as an electrocatalyst, while the PEDOT:PSS plays a role of a conductive binder to facilitate electron transfer between the MoSe_2 and the substrate. The weight ratios of MoSe_2 and PEDOT:PSS (MP) in the composites varied from 0.25 to 2.00. Each composite film contained 50 mg of MoSe_2 powder and 200 mg, 100 mg, 50 mg, and 25 mg of PEDOT:PSS, which are respectively referred to as MP-0.25, MP-0.50, MP-1.00, and MP-2.00, as per the ratios. The DSSC with a MP-1.00 composite film (equal weights of MoSe_2 and PEDOT:PSS) CE exhibits the highest electrocatalytic activity for the reduction of I_3^- . The DSSC containing the MoSe_2 NS/PEDOT:PSS composite film based CE shows a PCE of 7.58%, compared to the Pt CE exhibiting a PCE of 7.81% under similar experimental conditions. When MoSe_2 NS/PEDOT:PSS composite films coated on a titanium (Ti) foil flexible substrate was used as CE, the DSSC showed a PCE of 8.51%, compared to a PCE of 8.21% for the Pt-coated Ti foil CE. The CEs in the DSSCs show the relative order of the electrocatalytic activity as Pt > MP-1.00 > bare MoSe_2 > bare PEDOT:PSS, which is the same as observed by the IPCE spectra. The MP-1.00 composite film shows larger values of the heterogeneous rate constant, and the effective catalytic surface area as compared to bare MoSe_2 and bare PEDOT:PSS, because of MoSe_2 NS contents. The $R_{\text{CT-Tafel}}$ values of $3.23 \Omega \text{ cm}^2$ for Pt, $181.46 \Omega \text{ cm}^2$ for bare PEDOT:PSS, $3.77 \Omega \text{ cm}^2$ for MP-1.00, and $3.11 \Omega \text{ cm}^2$ for bare MoSe_2 were observed. The electrocatalytic ability of the CEs follow a trend seen in the R_{CT} values measured from Tafel polarization curves and EIS. The MoSe_2 NS/PEDOT:PSS composite film based CEs thus show potential to replace a costly Pt electrode.

A cobalt selenide ($\text{Co}_{0.85}\text{Se}$)/ MoSe_2 /molybdenum oxide (MoO_3) ternary hybrid was evaluated as a CE for DSSCs.²⁶⁶ $\text{Co}_{0.85}\text{Se}/\text{MoSe}_2/\text{MoO}_3$ ternary hybrids consist of nanorods, nanosheets, and nanoparticles, as confirmed by FESEM. CV showed larger current density for the $\text{Co}_{0.85}\text{Se}/\text{MoSe}_2/\text{MoO}_3$ hybrid compared with a sputtered Pt CE. The $\text{Co}_{0.85}\text{Se}/\text{MoSe}_2/\text{MoO}_3$ CE based DSSCs showed a PCE of 7.10%, much higher than that of a DSSC with a Pt CE ($\eta = 6.03\%$). For comparison, the $\text{Co}_{0.85}\text{Se}$ hollow nanoparticles as a CE for DSSCs showed a PCE of 6.03%, lower compared to the Pt CE based DSSC ($\eta = 6.45\%$).²⁶⁷ The transparent CEs using metal selenides alloys (M-Se; M = Co, Ni, Cu, Fe, Ru) were studied for the electrocatalytic activity for DSSCs and triiodide (I_3^-) reduction.²⁶⁸ The DSSCs containing CEs consisting of a metal selenide alloy showed PCEs of 8.30% for $\text{Co}_{0.85}\text{Se}$, 7.85% for $\text{Ni}_{0.85}\text{Se}$, 6.43% for $\text{Cu}_{0.50}\text{Se}$, 7.64% for FeSe , and 9.22% for $\text{Ru}_{0.33}\text{Se}$. A Pt CE based DSSC exhibited PCE of 6.18%. Also, a nickel cobalt sulfide (NiCo_2S_4) nanoneedle array²⁶⁹ used as a CE for a DSSC showed a PCE value of 6.9%, which is comparable to a Pt CE ($\eta = 7.7\%$).

4.2 NbSe₂ counter electrodes

Niobium diselenide (NbSe₂) has attracted attention due to its superconducting properties^{270–275} and can be easily processed into nanosheets, nanoflakes, nanowires and nanotubes usable for applications in field-effect transistors,^{99a} light-emitting diodes,²⁷⁶ superconductors,²⁷⁷ and lithium batteries.²⁷⁸

NbSe₂ nanosheets, nanorods, and NbSe₂/C composites were used as CEs for DSSCs.²⁷⁹ The morphology and structure of the NbSe₂ materials were characterized by SEM, TEM, and XRD while their electrochemical properties were evaluated by CV, EIS, and Tafel polarization curve measurements. The CEs based on NbSe₂ nanorods and NbSe₂ nanosheets showed lower charge

transfer resistance and ionic diffusion. DSSCs having NbSe₂ nanosheet-based CEs achieved a PCE of 7.34%, which further increased to 7.80% for the NbSe₂/C composite-based CEs due to reduced series resistance, which is a PCE of 98.7% of the conventional Pt-based CEs ($\eta = 7.90\%$). Also, NbSe₂

nanostructures deposited *via* spray-coating were used to develop Pt-free CEs for DSSCs by Ibrahim *et al.*²⁸⁰ Fig. 22 shows SEM images and AFM height profiles of NbSe₂ nanosheets, nanorods, and nanoparticles, CV, *J*–*V* curves, IPCE spectra, and EIS (presented in Nyquist plots) of Pt and NbSe₂ nanostructures

based CEs used in DSSCs. The morphology of the synthesized NbSe₂ nanostructures was analyzed by SEM and AFM techniques. SEM analysis indicated the pristine NbSe₂ 2D sheets were 100 μm thick. The separate NbSe₂ nanosheets were between 100–500 nm in lateral dimension. The length of NbSe₂ nanorods were up to 1.2 μm with diameters ranging between 20 to 100 nm. The average size of the NbSe₂ nanoparticles was between 50–100 nm. The AFM images revealed an average thickness of <8 nm for the NbSe₂ nanosheets, <5 nm for the NbSe₂ nanorods, and <3 nm for the NbSe₂ nanoparticles. HRTEM of the NbSe₂ nanosheets on their edge showed a spacing of 6.3 Å. HRTEM revealed the crystalline nature of individual NbSe₂ nanorods and nanoparticles. The NbSe₂

nanosheets, nanorods and nanoparticles were studied as CEs in DSSCs as a replacement to a conventional Pt CE. The dye-absorbed TiO₂ electrodes were prepared by dipping electrodes into ruthenium dye 719 solution for 24 hours at room temperature. The dye solution contained 0.5 mM dye N719, [*cis*-di(thiocyanato)-*N,N*-bis(2,20-bipyridyl-4-carboxylic acid-40-tetrabutyl-ammonium carboxylate) ruthenium(II)], and 0.5 mM chenodeoxycholic acid in a 1 : 1 mixture of *tert*-butanol and acetonitrile. The electrolyte solution was composed of 1-butyl-3-methylimidazolium iodide (BMII, 0.6 M), 4-*tert*-butylpyridine (0.5 M), iodine (0.03 M), and guanidinium thiocyanate (0.1 M) in a acetonitrile–valeronitrile mixture. The NbSe₂ nanosheet CEs achieved a PCE of 7.73%, compared to a PCE of 7.01% for

Pt-based CEs for DSSCs. The DSSCs with NbSe₂ nanoparticles and nanorods based CEs show PCE values of 6.27% and 5.05%, respectively, due to low FF arising from relatively smaller surface areas, as well as low exposure on the FTO glass substrates. DSSCs having NbSe₂ nanosheets based CE show the best IPCE spectral response, where the peak increases from 84% for a Pt CE to 89% for a NbSe₂ nanosheets based CE. On the other hand, lower IPCE peak values were observed for NbSe₂ nanoparticles and nanorods based CEs. The charge-transfer processes at the interface of TiO₂/dye/electrolyte were analyzed by EIS. The NbSe₂ nanosheet based CEs for the DSSCs shows a middle-frequency semicircle, implying it had the highest electro-catalytic activity for the reduction of triiodide ions (I₃[−]), and efficient generation of electrons, therefore, occurring of larger electrons at the TiO₂/dye/electrolyte interface. This study suggests that NbSe₂ nanosheets could be used as alternative CEs to conventional Pt CEs in DSSCs because of their large surface area.

4.3 TaSe₂ counter electrodes

Three transition-metal selenides (MoSe₂, WSe₂, and TaSe₂) were prepared by Guo *et al.*²⁸¹ and compared as potential CEs for fabricating DSSC devices using a solvothermal method. These transition-metal selenides show high electrocatalytic activity for the reduction of triiodide (I₃[−]), except for MoSe₂, due to low adsorption and charge-transfer. Fig. 23 shows SEM and TEM images of MoSe₂ (a and d), WSe₂ (b and e), and TaSe₂; the Nyquist plots of EIS measurements recorded at −0.75 V bias of the DSSCs based on MoSe₂, WSe₂, and Pt CEs for the triiodide/iodide (I₃[−]/I[−]) redox couple in the electrolyte; and their *J*–*V* curves measured under simulated sunlight illumination. The MoSe₂ nanosheets had thickness of about 10 nm with lateral dimensions ranging 100–150 nm. WSe₂ consists of interlaced nanoplates with 15 nm average thickness and a width varying between 60 and 100 nm. The SEM image of TaSe₂ shows fluffy nanoparticles with a wide size distribution. The HRTEM images of MoSe₂, WSe₂, and TaSe₂ indicated spacings of 0.282 nm, 0.283 nm, and 0.291 nm, respectively. The WSe₂ shows a pore size distribution (PSD) curve at about 43 nm, MoSe₂ at 30 nm, and TaSe₂ at 10 nm. The mesoporous structure of WSe₂ facilitates the adsorption of triiodide (I₃[−]) and transport during the electrocatalytic activity. The BET surface areas were 95.6, 104.4 and 78.8 m² g^{−1}, and the total pore volumes were 0.32 cm³ g^{−1}, 0.41 cm³ g^{−1} and 0.14 cm³ g^{−1}, for WSe₂, MoSe₂, TaSe₂, respectively. The significant difference in BET surface area and the pore size distribution led to different adsorption properties and electrocatalytic activity of the DSSCs. The *R*_{CT} of the transition-metal selenides at the electrolyte/electrode interface indicates the level of electrocatalytic activity. The *R*_{CT} value of 0.78 Ω cm² for the WSe₂ CE is smaller compared with a Pt CE (1.32 Ω cm²) and a TaSe₂ (1.89 Ω cm²) CE, while the *R*_{CT} value of the MoSe₂ (2.43 Ω cm²) CE was larger than that of the Pt CE. Therefore, WSe₂ shows better electrocatalytic activity for triiodide (I₃[−]) reduction. The ionic *Z*_N value of WSe₂ is 1.15 Ω cm², lower than that of the MoSe₂, and TaSe₂ CEs, and comparable to the Pt CE, which demonstrates a larger diffusion coefficient for

triiodide (I₃[−]) within the CEs. The conductivities measured by linear sweep voltammetry decrease in the relative order TaSe₂ > MoSe₂ > WSe₂. The DSSCs based on TaSe₂ and WSe₂ CEs showed larger *J*_{sc} than that of MoSe₂ CE. WSe₂ has larger pores and high electrocatalytic activity suitable for fast regeneration and transfer of triiodide (I₃[−]). PCE values of 7.32% for TaSe₂ and 7.48% for WSe₂ were measured, which are comparable to a sputtered Pt CE (*η* = 7.91%). The lower PCE value of 6.70% for MoSe₂ arises from a lower *V*_{oc} and *J*_{sc} for the DSSC.

4.4 NiSe₂ counter electrodes

Nickel diselenide (NiSe₂) has been studied as a CE of DSSCs for the reduction of I₃[−], which yielded higher PCE of 8.69% than that of a conventional Pt CE (8.04%) under the same experimental conditions.²⁸² Zhang *et al.*²⁸³ developed two types of NiSe₂ CEs on RGO; namely, microsphere NiSe₂/RGO, and octahedron NiSe₂/RGO through a hydrothermal process. The microsphere NiSe₂/RGO CE exhibited higher electrocatalytic performance than a Pt CE for the reduction of triiodide (I₃[−]) because of better carrier transfer induced by graphene nanosheets.

CEs of ternary Ni–Co compounds having different morphological structures such as nanoparticles, nanotubes, nanowires, nanoflakes, flower-like, and urchin-like have been studied for DSSCs.^{284,285} For example, the CE made of flower-like NiCo₂S₄/NiS microspheres²⁸⁶ exhibited a PCE of 8.8%, much higher than a standard Pt CE (*η* = 8.1%). A similar concept was employed by Qian *et al.*²⁸⁷ for developing a very interesting class of CEs for DSSCs from nickel cobalt (Ni–Co) selenides having different morphological structures, due to the tuning of the Ni/Co molar ratios. The morphological structure and electrocatalytic performance of ternary Ni–Co selenides was optimized by using different Ni/Co molar ratios. Fig. 24 shows the SEM images of Co₃Se₄, Ni_{0.33}Co_{0.67}Se precursor, Ni_{0.33}Co_{0.67}Se, Ni_{0.5}Co_{0.5}Se, Ni_{0.67}Co_{0.33}Se, and NiSe, and also shows CV and *J*–*V* curves of their DSSCs. The different morphological structures were obtained by tuning the Ni/Co molar ratio, Ni_xCo_{1−x}Se, where, *x* was 0, 0.33, 0.5, 0.67, and 1.0. The 3D dandelion-like precursor of Ni_{0.33}Co_{0.67}Se assembled into nanotubes having about 100 nm diameter, Ni_{0.5}Co_{0.5}Se into a floccus-like microsphere structure with a diameter of 4 microns, Ni_{0.67}Co_{0.33}Se microspheres compiled into nanosheets, and Co₃Se₄ built up rough-surface nanotubes. The specific surface areas determined from the BET method were 5.0, 10.1, 26.1, 28.9, and 35.6 m² g^{−1}, for NiSe, Co₃Se₄, Ni_{0.5}Co_{0.5}Se, Ni_{0.67}Co_{0.33}Se and Ni_{0.33}Co_{0.67}Se, respectively. Among all metal selenides, Ni_{0.33}Co_{0.67}Se has the highest specific surface area, which is favorable for providing more active sites for catalysis and increasing the contact area between its CE and the electrolyte, which results in better electrochemical and photovoltaic properties of its DSSCs. The *R*_{CT} values of CEs follows the relative order of NiSe > Co₃Se₄ > Pt > Ni_{0.67}Co_{0.33}Se > Ni_{0.5}Co_{0.5}Se > Ni_{0.33}Co_{0.67}Se, which implies that the electrocatalytic activity increases in a reverse order. Thus, NiSe was of the lowest activity and Ni_{0.33}Co_{0.67}Se was of the highest catalytic activity for the reduction of triiodide (I₃[−]). Therefore, higher contents of Ni in the Ni–Co selenides CEs are

Fig. 24 SEM images of (a) Co_3Se_4 , (b) $\text{Ni}_{0.33}\text{Co}_{0.67}\text{Se}$ precursor, (c–e) $\text{Ni}_{0.33}\text{Co}_{0.67}\text{Se}$, (f and g) $\text{Ni}_{0.5}\text{Co}_{0.5}\text{Se}$, (h) $\text{Ni}_{0.67}\text{Co}_{0.33}\text{Se}$, and (i) NiSe . (j) CVs of DSSCs with Co_3Se_4 , $\text{Ni}_{0.33}\text{Co}_{0.67}\text{Se}$, $\text{Ni}_{0.5}\text{Co}_{0.5}\text{Se}$, $\text{Ni}_{0.67}\text{Co}_{0.33}\text{Se}$, NiSe , and Pt-based CEs at a scan rate of 50 mV s^{-1} . (k) Photocurrent density–voltage ($J-V$) curves of DSSCs with Co_3Se_4 , $\text{Ni}_{0.33}\text{Co}_{0.67}\text{Se}$, $\text{Ni}_{0.5}\text{Co}_{0.5}\text{Se}$, $\text{Ni}_{0.67}\text{Co}_{0.33}\text{Se}$, NiSe , and Pt CEs under AM 1.5G illumination. Reprinted with permission from ref. 287, X. Qian, H. Li, L. Shao, X. Jiang and L. Hou, morphology-tuned synthesis of nickel cobalt selenides as highly efficient Pt-free counter electrode catalysts for dye-sensitized solar cells. *ACS Appl. Mater. Interfaces*, 2016, 8, 29486–29495. not favorable for electrocatalytic activity. The values of cathodic peak current density (red-1) and the E_{pp} can also help understand the electrocatalytic activities of these CEs. The authors noted the following relative order of cathodic peak current

density: NiSe (1.044 mA cm^{-2}) < Co_3Se_4 (1.849 mA cm^{-2}) < Pt (2.373 mA cm^{-2}) < $\text{Ni}_{0.67}\text{Co}_{0.33}\text{Se}$ (2.878 mA cm^{-2}) < $\text{Ni}_{0.5}\text{Co}_{0.5}\text{Se}$ (2.917 mA cm^{-2}) < $\text{Ni}_{0.33}\text{Co}_{0.67}\text{Se}$ (3.120 mA cm^{-2}). They also noted E_{pp} values of NiSe (602 mV) > Co_3Se_4 (565 mV) > Pt (460

mV) > Ni_{0.67}Co_{0.33}Se (365 mV) > Ni_{0.5}Co_{0.5}Se (349 mV) > Ni_{0.33}Co_{0.67}Se (329 mV), which were in an agreement with EIS measurements of the CEs. The 3D dandelion-like Ni_{0.33}S_{0.67}Se microspheres based CEs exhibited the highest PCE of 9.01%, exceeding that of the Pt CE ($\eta = 8.30\%$). The DSSC with a Co₃Se₄ CE showed a PCE of 7.95%, higher than that of NiSe CE ($\eta = 7.23\%$). These results support the notion that the ternary Ni-Co selenides possess higher electrocatalytic activities and photovoltaic properties than those of binary selenides NiSe and Co₃Se₄ as well as Pt CEs for the triiodide (I₃[−]) reduction, due to their unique morphology and chemical composition.

4.5 FeSe₂ counter electrodes

Iron diselenide (FeSe₂) can be processed into nanosheets, nanocubes, flower-like structures, and nanorods, rod clusters, and microspheres,^{288–294} and has applications in catalysis,²⁹⁵ batteries,^{296,297} and photovoltaic devices.²⁹⁸ The first-row (3d) transition metal dichalcogenides (MX₂) with pyrite structure (where, M = Fe, Co, Ni, and X = S, Se) also exhibit electronic, optoelectronic, and magnetic properties comparable to other TMDs.^{299–302} Huang *et al.*³⁰² used 2D FeSe₂ nanosheets with 7 nm average thickness as a CE for a DSSC. Fig. 25 shows the SEM and TEM images of the synthesized FeSe₂ nanosheets. The thickness of FeSe₂ nanosheets was found to be in the 4–7 nm range, as evaluated by TEM images. High-resolution TEM (HRTEM) indicated the crystalline nature of the nanosheets, having 0.168 nm interplanar spacing. The FeSe₂ nanosheets had specific surface area of 35.02 m² g^{−1} as calculated by the BET analysis. The FeSe₂ nanosheets exhibit a low charge-transfer resistance (R_{CT}) and a high electrocatalytic activity for triiodide (I₃[−]) reduction in DSSCs. The FeSe₂ nanosheets CE based DSSC showed a PCE of 7.53%, comparable to a Pt CE, while the PCE of FeSe₂ microparticles CE based DSSC was slightly lower (η

= 6.88%). The large surface area of the FeSe₂ nanosheets contributed to a higher PCE by providing more active sites for electrocatalytic activity, as well as a larger electrode/electrolyte interface that of the FeSe₂ microparticles. The electrochemical stability of the CEs of FeSe₂ nanosheets and Pt were investigated with sequential CV scanning. The current densities of the FeSe₂ CE showed no change after 1000 cycles, confirming corrosion resistance to the electrolyte. The PCEs of FeSe₂ nanosheets under nitrogen protection (N-FeSe₂) and exposure to air for one week (O-FeSe₂) were also studied. The R_{CT} of the N-FeSe₂ CE (0.53 Ω cm²) was much lower than the O-FeSe₂ CE (10.13 Ω cm²) and a Pt CE (1.68 Ω cm²), indicating poorer electrocatalytic activity of the O-FeSe₂ CE compared to the N-FeSe₂ and Pt CEs. The Tafel polarization curves decreased in the order N-FeSe₂ > Pt > O-FeSe₂, having the same order as of exchange current density, CV and EIS measurements. The O-FeSe₂ nanosheets CE based DSSC has a PCE of 6.15%, much lower than that of the N-FeSe₂ ($\eta = 7.53\%$) CE and Pt CE ($\eta = 7.47\%$) under similar conditions.

3D hierarchical FeSe₂ microspheres using a hot-injection method were prepared and studied by Huang *et al.*³⁰³ The morphologies of the FeSe₂ nanomaterials was controlled by the use of alkyl thiols; 1-dodecanethiol (1-DDT) or *tert*-dodecanethiol (*t*-DDT) and their contents were used in synthesis, which varied from irregular FeSe₂ micro/nanoparticles to 3D hierarchical FeSe₂ microspheres and consisted of ultrathin FeSe₂ nanosheets or urchin-like microspheres made of crystalline FeSe₂ nanorods having an average diameter of 650 nm. The FeSe₂ nanomaterials were used as CEs for DSSCs. 3D hierarchical FeSe₂ microspheres made of ultrathin FeSe₂ nanosheets showed the lowest R_{CT} of 0.49 Ω cm² at the electrolyte/electrode interface, a lower Z_N value of 0.39 Ω cm², and faster reaction kinetics for the reduction of I₃[−] to I[−] than that of a Pt CE (R_{CT} of 1.15 Ω cm² and Z_N value of 0.91 Ω cm²). R_{CT} values followed the relative order of FeSe₂ microparticles < FeSe₂ nanorods < Pt < FeSe₂ nanosheets, as supported by EIS measurements. A DSSC with a FeSe₂ nanosheets CE exhibited a PCE of 8.39%, slightly better than that of a Pt CE (8.20%) under simulated solar illumination of 100 mW cm^{−2} (AM 1.5). FeSe₂ nanorods showed a PCE value of 8.03%, higher than that of FeSe₂ microparticles (7.68%). The PCE value of DSSCs is morphology dependent, where the FeSe₂ nanosheets CE has a high electrocatalytic activity and a larger specific surface area (30.03 m² g^{−1}) than that of FeSe₂ nanorods (19.82 m² g^{−1}). The FeSe₂ nanosheets CE based DSSC retained 99.5% of its initial photocurrent density, compared to 98.3% retained by the Pt CE, after simulated solar illumination of 100 mW cm^{−2} for 1 hour, and this indicates better stability of the FeSe₂ nanosheets CE than that of standard Pt CE. Also, the 3D flower-like and sphere-shaped FeSe₂ films were used as CEs for DSSCs.³⁰⁴ The 3D flower-like FeSe₂-based CE exhibited a comparable PCE to a Pt CE ($\eta = 8.00\%$ versus 7.87%).

(e) Photocurrent–voltage (J – V) curves of the DSSCs with $\text{CoSe}_2/\text{C-NCW}$ on flexible nickel foam (NF) CE, measured at light intensities varying from 20 mW cm^{-2} (0.2 Sun) to 100 mW cm^{-2} (1 Sun). (f) Photocurrent–voltage (J – V) curves of the DSSCs with $\text{CoSe}_2/\text{C-NCW}$ on flexible carbon cloth (CC) CE, under similar light intensities. Reprinted with permission from ref. 310, I. T. Chiu, C. T. Li, C. P. Lee, P. Y. Chen, Y. H. Tseng, R. Vittal and K. C. Ho, nanoclimbing-wall-like CoSe_2 /carbon composite film for the counter electrode of a highly efficient dye-sensitized solar cell: a study on the morphology control. *Nano Energy*, 2016, 22, 594–606. Copyright© Elsevier.

nanorods synthesized by a hydrothermal method was studied as CEs for DSSCs.³⁰⁹ FESEM revealed a CoSe_2 nanorod morphology of the CoSe_2 , which supports carrier transport from the surface of the nanorods to the redox electrolyte. The CoSe_2 CE also exhibited larger current density compared with a Pt CE, as measured by CV. EIS shows an R_s of $8.034 \Omega \text{ cm}^2$ and a low R_{CT} of $0.097 \Omega \text{ cm}^2$ for the CoSe_2 CE. The DSSC with a CoSe_2 CE showed a PCE value of 8.38%, higher than the DSSC based on a Pt CE ($\eta = 7.83\%$), under simulated sunlight illumination of 100 mW cm^{-2} (AM 1.5G).

A comprehensive and detailed study was conducted by Chiu *et al.*³¹⁰ on composite films of CoSe_2 /carbon (CoSe_2/C) deposited on FTO substrates having three different morphologies, developed using electro-deposition, followed by an annealing process at 500°C for 30 minutes in vacuum. In the first stage, three types of CoSe_2 /carbon films containing nanowalls were deposited with an electro-deposition process employing different pH baths, while in the second stage, the morphology of the films was transformed after the annealing. The N719 dye-adsorbed TiO_2 film was used as a photoanode for DSSCs. CoSe_2/C films had three different morphologies, including nanograin (NG), nanorock (NR), and nanoclimbing-wall (NCW), which were used as CEs for DSSCs. The electrocatalytic activity of these three CEs was analyzed by CV, RDE, Tafel polarization curves, and EIS, which showed a relative order of $\text{CoSe}_2/\text{C-NCW} > \text{CoSe}_2/\text{C-NG} > \text{Pt} > \text{CoSe}_2/\text{C-NR}$ as CEs in the DSSCs, a similar order as was

observed for the R_{CT} values obtained by EIS and Tafel measurements. The $\text{CoSe}_2/\text{C-NCW}$ showed higher electrical conductivity and a large effective surface area and, therefore, the best electrocatalytic ability for triiodide (I_3^-) reduction. The DSSCs with $\text{CoSe}_2/\text{C-NG}$, $\text{CoSe}_2/\text{C-NCR}$, $\text{CoSe}_2/\text{C-NCW}$, and Pt CEs exhibited IPCE values between 80–95% in the 400 to 600 nm wavelength region, where the highest IPCE value of 95% was observed for the $\text{CoSe}_2/\text{C-NCW}$ CE. The DSSC having a $\text{CoSe}_2/\text{C-NCW}$ CE showed the highest PCE value of 8.92%, even higher than compared with the Pt CE (8.25%). The $\text{CoSe}_2/\text{C-NCW}$ CEs were electro-deposited onto low-cost, flexible, and highly porous substrates, such as carbon cloth (CC, sheet resistance = $0.63 \Omega \text{ sq}^{-1}$) and nickel foam (NF, porosity = 95%, sheet resistance = $0.45 \Omega \text{ sq}^{-1}$). Fig. 26 shows photographs of the flexible nickel foam (NF) and carbon cloth (CC), SEM images of $\text{CoSe}_2/\text{C-NCW}$ film on the flexible NF and CC substrates, and J – V curves of the DSSCs, with $\text{CoSe}_2/\text{C-NCW}$ on NF and CC CEs measured at different light intensities (20–100 mW cm^{-2}). The $\text{CoSe}_2/\text{carbon-NCW}$ CEs shell covered all the minute parts of the carbon cloth and nickel foam core shell structures. The DSSC containing the CE with $\text{CoSe}_2/\text{C-NCW}$ deposited on nickel foam exhibited the highest PCE of 10.46% at 100 mW cm^{-2} (1 Sun) and 7.90% at 20 mW cm^{-2} (0.2 Sun). The DSSC with the CE of $\text{CoSe}_2/\text{C-NCW}$ deposited on low-weight carbon cloth showed a PCE of 9.87% at 1 Sun and 7.83% at 0.2 Sun. The low cost and flexible $\text{CoSe}_2/\text{C-NCW}$ CEs seem to be promising materials to

Table 4 Photovoltaic parameters of MoSe₂, WSe₂, TaSe₂, NbSe₂, FeSe₂, CoSe₂ and Bi₂Se₃ based CEs for DSSCs. FTO glass is the common substrate used in assembling the DSSCs with different CE materials. The measurements were conducted at a simulated solar light intensity of 100 mW cm⁻² (AM 1.5G) unless specified. The photovoltaic parameters short-circuit photocurrent density (J_{sc}), open-circuit voltage (V_{oc}), fill factor (FF), and power conversion efficiency (η), series resistance (R_s), charge-transfer resistance (R_{CT}), electrolyte and dye used for DSSCs are summarized and compared with a standard Pt CE^a

^a Nanograin (NG), nanorock (NR), nanoclimbing-wall (NCW), nickel foam (NF), carbon cloth (CC), rGO = reduced graphene oxide. In the case of R_s and R_{CT} : some of the authors used Ω instead of Ω cm² for the resistances without mentioning the size of the electrode.

replace expensive Pt CE for DSSCs for indoor, outdoor or wearable applications.

CoSe₂ and RGO composites were also explored as CE in DSSCs, which showed a PCE of 7.01% *versus* a Pt CE (η = 6.77%).³¹¹ Co_{0.85}Se and Ni_{0.85}Se was deposited on FTO glass substrate by a low-temperature hydrothermal process and were used as CE for DSSCs by Gong *et al.*³¹² Co_{0.85}Se has a graphene-like nanostructure and possesses a large surface area, while Ni_{0.85}Se is composed of aggregated particles. The graphene-like Co_{0.85}Se CE showed higher electrocatalytic activity than that of

the Pt CE for the reduction of triiodide (I₃⁻). DSSCs with Co_{0.85}Se CE showed a PCE of 9.40%, significantly higher than that of a Pt CE (8.64%), under simulated solar light of 100 mW cm⁻² (AM 1.5G). In the case of the Ni_{0.85}Se CE, the PCE of 8.32% was slightly lower than a Pt CE. Both J_{sc} and PCE values showed a relative order of Ni_{0.85}Se < Pt < Co_{0.85}Se. The R_{CT} value was found to increase in the relative order Co_{0.85}Se (0.6 Ω cm²) < Pt (1.1 Ω cm²) < Ni_{0.85}Se (1.8 Ω cm²), suggesting an inverse order of electrocatalytic activity of these CE in the DSSCs. Table 4 summarizes the photovoltaic parameters of MoSe₂, WSe₂,

TaSe₂, NbSe₂, FeSe₂, CoSe₂ and Bi₂Se₃ based CEs for DSSCs, and their comparison with a standard Pt CE.

4.7 Bi₂Se₃ counter electrodes

Bismuth selenide (Bi₂Se₃) and bismuth telluride (Bi₂Te₃) have been previously studied as topological insulators.^{313,314} Bi₂Se₃, a semiconducting and thermoelectric material, can be processed into single layers, nanosheets, nanotubes, nanoribbons, and nanowires^{315–318} and has applications in field-effect transistors,³¹⁹ sensors,³²⁰ non-volatile memory devices,³²¹ photovoltaic devices,³²² and drug delivery and anti-cancer therapy.^{323,324} Bi₂Se₃/RGO nanocomposites were prepared by a microwave-assisted hydrothermal method as a CE for a DSSC by Zhu *et al.*³²⁵ Fig. 27 shows the TEM images of the graphene nanosheets, Bi₂Se₃ nanospheres and Bi₂Se₃/graphene nanocomposites containing 60 mg graphene contents. The TEM images showed that 10–15 nm Bi₂Se₃ nanoparticles were attached onto graphene nanosheets. SEM images showed that the graphene had a flake-like structure while the Bi₂Se₃ nanoparticles were large size spheres. Furthermore, the surface of the graphene oxide was found to be very smooth in comparison with graphene nanosheets doped with Bi₂Se₃ nanoparticles. The inclusion of Bi₂Se₃ nanoparticles onto graphene nanosheets was controlled to achieve high electrocatalytic activity of the CE for the reduction of triiodide (I₃[−]). The DSSC with a Bi₂Se₃/graphene (60 mg) CE yielded a high PCE of 7.09%,

which is comparable to a Pt CE ($\eta = 6.23\%$). The Bi₂Se₃/graphene nanocomposite CEs with 40 mg and 80 mg graphene content showed PCE values of 6.35% and 6.66% for the DSSCs, respectively, which was much higher than that of pure Bi₂Se₃ CE ($\eta = 1.86\%$), but still comparable to a Pt CE.

5. Bi₂Te₃ based photoanodes

Bismuth telluride (Bi₂Te₃) has been studied for thermoelectric applications and can be processed into nanowires arrays,^{326–329} nanotubes,³³⁰ nanoplates,³³¹ nanosheets,^{332,333} and thin films.³³⁴ Dou *et al.*³³⁵ developed hybrid photoanodes by dispersing Bi₂Te₃ nanotubes into ZnO nanoparticles. The 0.5, 1.0, 1.5, 2.0, and 2.5 wt% of highly crystalline Bi₂Te₃ nanotubes were mixed with ZnO nanoparticles to fabricate photoanodes for DSSCs. Pt films deposited on FTO glass was used as a CE. The electrolyte consisted of 0.05 M I₂, 0.5 M LiI, and 0.1 M 4-*tert*-butylpyridine in acetonitrile-propylene carbonate (1 : 1) solution. In the Bi₂Te₃/ZnO hybrid, Bi₂Te₃ nanotubes provided a conduction pathway which facilitated electron transfer. The J_{sc} value increased gradually with increasing Bi₂Te₃ nanotubes content up to 1.5 wt% (11.767 mA cm^{−2}) and then started decreasing as the Bi₂Te₃ nanotubes content exceeded 2.0 wt% (9.957 mA cm^{−2}), due to the low dye loading on the surface of ZnO nanoparticles. A similar trend was observed for the PCE values. The DSSCs with

Fig. 27 TEM images of (a) graphene nanosheet, (b) Bi₂Se₃ nanospheres (c) and (d) Bi₂Se₃/graphene nanocomposite (60 mg graphene). Reprinted with permission from ref. 325, L. Zhu, K. Y. Cho and W. C. Oh, microwave-assisted synthesis of Bi₂Se₃/reduced graphene oxide nanocomposite as efficient catalytic counter electrode for dye-sensitized solar cell, *Fullerenes, Nanotubes, Carbon Nanostruct.*, 2016, **24**, 622–629. Copyright© Taylor & Francis Group.

a $\text{Bi}_2\text{Te}_3/\text{ZnO}$ composite photoanode containing 1.5 wt% Bi_2Te_3 nanotubes in the ZnO photoanode showed a PCE of 4.27%, which is 44.3% higher compared with a pure ZnO photoanode. The PCE values were 2.96% for the bare ZnO photoanode, and 3.74, 3.96, 4.27, 3.41 and 3.01% for the 0.5, 1.0, 1.5, 2.0 and 2.5 wt% Bi_2Te_3 nanotubes content photoanodes, respectively. This study indicated that loading of thermoelectric Bi_2Te_3 in a ZnO photoanode improves the photovoltaic performance of DSSCs. Wan *et al.*³³⁶ prepared hexagonal Bi_2Te_3 nanosheets of 300–400 nm length by a hydrothermal method. The nanocomposites of the Bi_2Te_3 nanosheets and ZnO nanoparticles were used as photoanodes for DSSCs, where the Bi_2Te_3 nanosheet concentration was varied from 0 to 0.25 wt%. The DSSCs with 0.15 wt% of Bi_2Te_3 nanosheets in the Bi_2Te_3 nanosheet/ZnO nanoparticle composite photoanode showed a PCE of 4.10%, which was improved by 46.95% compared with the bare ZnO photoanode. The thermoelectric Bi_2Te_3 nanosheets in the composite photoanode helped in enhancing the electron density and reducing the temperature of the DSSCs. The Bi_2Te_3 nanosheet/ZnO nanoparticles composite photoanode significantly improved the DSSC performance. A thermoelectric $\text{Bi}_2\text{Te}_3/\text{TiO}_2$ composite based photoanode was also used for DSSCs, where Bi_2Te_3 nanoplates help in converting heat into electricity and enhanced the rate of charge transfer.³³⁷ This resulted in a 28% increase of the PCE of the DSSC. The Bi_2Te_3 nanoplates have also been used for doping TiO_2 photoanodes.³³⁸ The effect of Bi_2Te_3 nanoplates size was evaluated for DSSCs, where a decrease in the size of the Bi_2Te_3 nanoplates led to and higher PCE. The performance of DSSCs with a $\text{Bi}_2\text{Te}_3/\text{TiO}_2$ photoanode increased by 15.3% compared to the undoped TiO_2 photoanode.

6. Long-term stability of TMDs based DSSCs

The long-term stability of DSSCs is one of the most important parameters for commercial applications. The stability of DSSC devices depends upon a number of factors and the components used in their fabrication. The decrease in power conversion

efficiency of a DSSC can be associated with the stability of different electrolyte components, photosensitizing dyes, aging of the TiO_2 photoanode, degradation of the CE (cathode), corrosion of components by electrolytes, sealant, leakage, exposure to solar irradiation, high humidity, and elevated temperature.^{339–349}

A few research reports have been published on the long-term stability of TMDs based DSSCs which are briefly discussed here. Infant *et al.*¹³¹ studied the stability of CVD-deposited vertically oriented MoS_2 thin films on an FTO surface used as a CE in a DSSC. The electrochemical stability of a MoS_2 CE based DSSC was analyzed by CV measurements, where electrodes were repeatedly subjected to 20 cycles at a 10 mV s^{-1} scan rate for the I^-/I_3^- redox couple in the electrolyte. The MoS_2 based CE showed no significant change up to 20th consecutive cycle, whereas the Pt CE exhibited some changes between the cycles (Fig. 28). This confirms that CVD deposited MoS_2 strongly adhered onto the surface of the FTO substrate. The stability of MoS_2 CEs was measured under ambient conditions by storing them for 15 days, where the PCE remained at 94% of its initial efficiency value, which was much higher than that of the Pt CE.

For preparing Pt-free dye-sensitized solar cells, Liu *et al.*³⁵⁰ fabricated DSSCs using MoS_2 and RGO composite as a CE for the reduction of triiodide (I_3^-) to iodide (I^-). AFM, XPS, and XRD confirmed the deposition of MoS_2 nanoparticles onto the RGO surface. The CV measurement showed a higher current density for the MoS_2/RGO nanocomposite based CE compared to RGO, MoS_2 , and Pt-sputtered CEs due to an increased surface area. The MoS_2/RGO CE also exhibited a low R_{CT} of $0.57 \Omega \text{ cm}^2$ for the reduction of triiodide (I_3^-) to iodide (I^-). The MoS_2/RGO nanocomposite CE based DSSC showed a PCE of 6.04%, comparable to a PCE of 6.38% for the conventional Pt CE. MoS_2/RGO nanocomposites based CEs also have better electrochemical stability, as no degradation in current densities was observed up to 100 repeated CV tests. The stability test conducted on a DSSC having MoS_2/RGO nanocomposites as CEs showed over 10% degradation in PCE over a period of 20 days, as depicted in (Fig. 29a). Therefore, MoS_2/RGO nanocomposites based CEs were found to be stable both for environmental and consecutive electrochemical tests. Li *et al.*²⁰⁰ prepared a composite film of $\text{TiS}_2/\text{PEDOT:PSS}$ on an ITO substrate as a CE

Fig. 28 Electrochemical properties of thin films of MoS_2 prepared at 600°C for 15 minutes. 20 consecutive cyclic voltammogram (CV) curve of MoS_2 (a) and Pt (b) counter electrodes recorded at the scan rate of 10 mV s^{-1} and (c) PCE of MoS_2 and Pt CEs based DSSCs measured for 15 days under ambient conditions. of DSSCs for the I[−]/I₃[−] redox system, which exhibited a PCE as high as 7.04% and is comparable to a Pt CE. Fig. 29b shows dark current density–voltage curves of DSSCs with Pt, bare TiS₂, bare PEDOT:PSS, and 10 wt% TiS₂/PEDOT:PSS composite CEs, and also the long-term stability of a 10 wt% TiS₂/PEDOT:PSS composite CE based DSSC. This another example of long-term stability of DSSCs based on TiS₂/PEDOT:PSS CEs.

The stability of DSSCs with a TiS₂/graphene hybrid CE was studied by Meng *et al.*¹⁹⁹ (Fig. 30). The TiS₂–graphene hybrid CE maintained 96% of its initial PCE value after 500 hours in air, also exhibiting higher electrochemical stability. The *R_s* and *Z_N* values for the TiS₂–graphene hybrid CE based DSSC did not change after 10 cyclic measurements. The *R_{CT}* value of a DSSC with Pt CE significantly increased with increasing cycling number, while there was no change in the *R_{CT}* value of the TiS₂–graphene hybrid after 10 cycles. This indicates better electrochemical stability of the TiS₂–graphene hybrid CE than the Pt CE. The stability of photovoltaic parameters of DSSCs having

Fig. 30 Stability of DSSCs with TiS₂–graphene hybrid and Pt CEs. Reprinted with permission from ref. 199, X. Meng, C. Yu, B. Lu, J. Yang and J. Qiu, dual integration system endowing two-dimensional titanium disulfide with enhanced triiodide reduction performance in dye-sensitized solar cells. *Nano Energy*, 2016, 22, 59–69. Copyright© Elsevier.

mesoporous CoS₂ nanotube arrays as CEs was recorded for 10 days by Tsai *et al.*²³³ a slight drop in the *V_{oc}* and FF values were observed, which resulted in a 2.2% decrease in the PCE of the CoS₂ nanotube array CEs. The photovoltaic parameters of the DSSC were quite stable up to 10 days, indicating good stability of DSSCs with mesoporous CoS₂ nanotube array CEs (Fig. 31).

The electrochemical stability of DSSCs with FeSe₂ nanosheets and Pt CEs in an iodine-based electrolyte was studied by Huang *et al.*³⁰² Both CEs were subjected to consecutively CV scanning. The FeSe₂ nanosheets-based CE showed no change in the current densities and *E_{pp}* values up to 1000 cycles, whereas the *E_{pp}* value for the Pt-based CE was observed to increase after 1000 consecutive cycles (Fig. 32). This study confirmed a better corrosion resistance of FeSe₂ nanosheets CE to the iodine-based electrolyte than a Pt CE. Both CEs were also subjected to sequential EIS scanning, where negligible changes in *R_{CT}* were noticed after 10 cycles, again indicating an excellent electrochemical stability of both CEs. Furthermore, *R_s* and *Z_N* values also showed no change upon repeated scanning cycles.

The stability of a FeS₂ nanorod based CE was also measured in an iodide (I[−]) electrolyte up to 10 days, and CV plots showed slight change at different times of aging.²²² The hydrothermally synthesized CoSe₂ nanorods were used as an electrocatalyst for a DSSC for the reduction of I₃[−] using N719 dye by Sun *et al.*³⁵¹ The single crystalline CoSe₂ nanorods based CE showed a PCE of 10.20%, compared with a PCE of 8.17% for a Pt CE, under 1 Sun illumination. The DSSCs having CoSe₂ CEs were stored in daylight and their photovoltaic properties were measured every day, and showed long-term stability. These studies show an excellent electrochemical stability of TMDs-based CEs for DSSCs in iodine-based electrolyte, with no corrosion. The TMDs CEs are also quite stable when stored under ambient conditions of up to 2–3 weeks, as no significant changes were observed in the PCEs of the DSSC devices. Furthermore, TMDs based CEs should be further investigated to exhibit better electrochemical stability and environmental stability than that of standard Pt CEs, and endurance tests should be carried out to study the their stability. The DSSS devices should have a service life of at least 20 years under ambient conditions as pointed out by

Fig. 31 Stability of photovoltaic parameters; open-circuit voltage (V_{oc}), short-circuit photocurrent density (J_{sc}), fill factor (FF), and power conversion efficiency (η) of DSSCs with mesoporous CoS_2 nanotube array CE as a function of time. Grätzel.³⁴² The long-term stability of DSSCs is feasible by carefully selecting components and solar cell structure. The TMDs based CEs may overcome the concerns associated with scarcity, high production cost, and corrosion of Pt CEs in electrolyte solutions. Researchers in this field should address the stability for of TMDs based CEs to evaluate the performance of Pt-free DSSCs.

Some achievements and strategies to overcome the long-term stability of Pt-free DSSCs are summarized in the following section. Kato *et al.*³⁵² used Raman spectroscopy and EIS to evaluate the durability of DSSCs for 2.5 years in outdoor conditions. Both N719 dye-adsorbed TiO_2 CEs and carbon CEs were found to be stable. The V_{oc} and FF values were slightly decreased because of increased Z_N of triiodide (I_3^-), arising

from the change in electrolyte components. Matsui *et al.*³⁵³ achieved stability over 1000 hours for DSSCs at 85°C and under 85% relative humidity, and recorded no degradation of the photovoltaic performance between -40 and 90°C for 200 cycles. Xue *et al.*³⁵⁴ measured thermal stability of DSSCs between -20 to 25°C temperature range for 1080 hours. DSSCs with N719 dye absorbed on the TiO_2 photoanode retained 80% of their initial PCE values after aging for 1080 hours. The deterioration of the N719 dye was found to be the main cause for a decrease the PCE and degradation of DSSC devices. Harikisun and Desilvestro³⁵⁵ evaluated photovoltaic performance of Z907-based DSSCs after continuous light-soaking at 55 – 60°C for 25 600 hours, where a slight degradation was observed. The accelerated aging tests predicted a life time of 40 years for Middle European conditions

while 25 years for Southern European conditions. The 10% and 20% decrease of photovoltaic performance was measured for ionic liquid and solvent based electrolytes over 1000 hours at 180 °C, respectively.

Strategies to improve the long-term stability of DSSCs include developing new photosensitizing dyes, new non-volatile electrolytes, encapsulation, and of course new photoanodes and CEs. Like the heterojunction solar cells,²⁷ several strategies for improving electrochemical and thermal stability of DSSC devices have been proposed. The role of photosensitizing dyes containing π -conjugated organic systems have been studied for the stability of DSSCs. Wu *et al.*³⁵⁶ suggested a novel concept of molecular engineering of donor-acceptor- π -acceptor (D-A- π -A) based photosensitizers, not only to improve the stability of DSSCs but also to enhance the photovoltaic performance. Katoh *et al.*³⁵⁷ compared the stability of five sensitizing dyes in DSSCs with and without π -conjugated oligothiophene moiety, which indicated that dyes with π -conjugated oligothiophene exhibit higher stability than those of without oligothiophene moiety. Joly *et al.*³⁵⁸ fabricated DSSCs with a new organic sensitizer (RK1) which showed a J_{sc} of 18.26 mA cm⁻², V_{oc} of 0.76 V, and FF of 0.74, resulting in a PCE value of 10.2% under 1 Sun illumination for the triiodide/iodide (I_3^-/I^-) redox couple. A similar PCE of 10.19% was achieved for the ruthenium N719 dye. When RK1 dye was used with a viscous ionic liquid electrolyte, the DSSC yielded a J_{sc} of 15.40 mA cm⁻², V_{oc} of 0.665 V, FF of 0.69, and a PCE of 7.36%, with outstanding stability. The DSSC exhibited no degradation of photovoltaic performance after visible-light soaking at 65 °C for 2200 hours, but, thereafter, DSSC started degrading and retained 75% of its initial PCE at 65 °C after 5000 hours.

A new coumarin dye, namely 2-cyano-3-[5'-[1-cyano-2-(1,1,6,6-tetramethyl-10-oxo-2,3,5,6-tetrahydro-1*H*,4*H*,10*H*-11-oxa-3*a*-aza-benzo[*de*]anthracen-9-yl)-vinyl]-[2,2']bithiophenyl-5-yl]-acrylic acid (NKX-2883) was developed by Wang *et al.*³⁵⁹ to examine the stability of DSSCs in a nonvolatile electrolyte made of 0.1 M I_2 , 0.6 M 1,2-dimethyl-3-*n*-propylimidazolium iodide (DMPII), and 0.1 M *N*-methylbenzimidazole (NMBI) in 3-methoxypropionitrile. The NKX-2883 dye-based DSSC showed a J_{sc} value of 18.8 mA cm⁻² and a PCE of 6.5% with 6 micron thick TiO_2 film. The DSSCs maintained a PCE of 6% under continuous light soaking of 100 mW cm⁻² (1 Sun illumination) at 50–55 °C for 1000 hours. Organic photosensitizing dyes having long alkyl chains were also proposed to improve long-term stability for both liquid and quasi-solid-state DSSCs.³⁶⁰ In another study, quinoxaline based metal-free organic sensitizing dyes were utilized to introduce long-term stability in DSSCs.³⁶¹ The length of the alkyl chains on the donor unit was found to affect the performance of DSSC devices. The quasi-solid-state DSSCs with a quinoxaline-based organic dye showed a PCE of 7.14%, and maintained 100% of its initial PCE value after continuous sunlight irradiation for 1000 hours, indicating that molecular engineering of dye molecules can lead to both high PCE and long-term stability of DSSC devices.

The electrochemical stability of CEs in corrosive triiodide/iodide (I_3^-/I^-) electrolyte is of significant concern because it restricts commercial applications of DSSCs. To overcome this

disadvantage of the I^-/I_3^- redox couple, research activities have been focused on finding alternative iodine-free non-corrosive redox electrolytes.^{19,362–366} Cell-sealing conditions are also important when using liquid electrolytes. The DSSCs can be made suitable for outdoor applications by using encapsulation. The role of electrolytes has been studied in the stability of DSSCs by Sauvage *et al.*³⁶⁷ suggesting a new electrolyte based on butyronitrile solvent with low volatility, along with thiophene-based sensitizer Na-Ru(4,4'-bis(5-(hexylthio)thiophen-2-yl)-2,2'-bipyridine)(4-carboxylic acid-4'-carboxylate-2,2'-bipyridine)(thiocyanate)2, coded C106, for DSSCs which showed >95% retention of PCE value after 1000 hours at 60 °C for an exposure to 100 mW cm⁻² light illumination. Yoon *et al.*³⁶⁸ fabricated DSSCs with 1-propyl-3-methyl imidazolium iodide (PMII) ion-gel electrolyte with a poly(styrene-block-ethyleneoxide-block-styrene) (SEOS) triblock copolymer. The DSSC with ion-gel electrolyte retained 92% of its initial PCE up to 1440 hours, compared to 78% for the ionic liquid electrolyte. Lee *et al.*³⁶⁹ reported long-term stability of DSSCs with organic tetrabutylammonium iodide (TBAI) or 1-methyl 3-propyl imidazolium iodide (PMII) in methoxypropionitrile-based electrolytes. The DSSCs having TBAI retained 96.9% of their initial efficiency after being stored for 1000 hours under 1 Sun light irradiation at 60 °C. Yang *et al.*³⁷⁰ proposed the use of poly(ethylene oxide)-poly(vinylidene fluoride) (PEO-PVDF) polymer-blend electrolytes with water and ethanol for improving stability of DSSCs. The electrical conductivity was found to increase after adding water and ethanol to the PEO-PVDF polymer-blend electrolytes. The cross-linking capability of hydroxyl-rich additives for modified electrolytes was found to have a positive impact. Chen *et al.*³⁷¹ demonstrated the long-time durability of DSSCs by using a succinonitrile, silica nanoparticles and 1-butyl-3-methylimidazolium tetrafluoroborate (BMI·BF₄) gel system which maintained 93% of its initial PCE after aging at 60 °C for 1000 hours. Dembele *et al.*³⁷² also demonstrated that adding 1.0 wt% concentration of MWCNTs to TiO_2 photoanodes can improve both PCE and stability of a DSSC, where the PCE value increased to 4.1% compared with 3.7% for pure TiO_2 photoanodes. The performance of the DSSC devices was measured for 10 consecutive days under ambient light exposure. The PCE decreased about 10% for the MWCNTs/ TiO_2 photoanodes, compared to 35% decrease in pure TiO_2 photoanodes.

The long-term stability of Pt-free DSSCs is of significant importance for both indoor and outdoor applications and different approaches can be examined to improve environmental stability.^{356–361,367–377} These studies show that long-term stability may be introduced in TMDs based DSSCs by similar strategies of using long alkyl chain organic dyes, ion-gel and polymer-based electrolytes, silica nanoparticles, or modifying TiO_2 photoanodes. Similar electrochemical and thermal stability studies should be conducted for TMD CEs for DSSC devices.

7. Conclusion and perspective

The electrochemical and photovoltaic properties of DSSC devices employing CEs (CEs) of 2D layered transition metal

dichalcogenides (MoS₂, MoSe₂, WS₂, TiS₂, NbSe₂, TaSe₂, NiSe₂, FeSe₂, CoSe₂, SnS₂, Bi₂Se₃ and their based composites) have been summarized and discussed. This data indicates that the PCEs of TMDs-based CE surpasses conventional Pt CE in dye-sensitized solar cell (DSSC) devices. The composites of TMDs with graphene, CNTs, carbon, carbon nanofibers (CNFs), and PEDOT:PSS also show a great potential as CEs for DSSCs. The DSSCs having CEs made of chemical vapor deposition (CVD)-grown vertically inclined MoS₂ films,¹³¹ hydrothermally prepared MoS₂ films,^{135,141} MoS₂ and MoSe₂ thin films deposited on Mo foil,^{260,261} MoS₂/graphene, MoS₂/CNTs,¹⁶⁴ MoS₂/carbon,¹⁷¹ and MoSe₂/PEDOT:PSS composites exhibit higher PCE values than that of Pt CE for the reduction of triiodide (I₃⁻) to iodide (I⁻). Furthermore, the CEs of TiS₂/graphene hybrids,¹⁹⁹ NiS₂/reduced graphene oxide (RGO) composites,²¹⁰ FeS₂,²²¹ NbSe₂,²⁸⁰ and FeSe₂ nanosheets³⁰² also show a better photovoltaic performance than that of Pt CE in DSSCs. The low cost and flexible CoSe₂/carbon-nanoclimbing-wall CE deposited on nickel foam shows the highest PCE of 10.46% *versus* a Pt CE ($\eta = 8.25\%$) at 1 Sun illumination (100 mW cm⁻² (AM 1.5G)).³¹⁰ It has been observed that the morphology of CEs also plays an important role in determining the electrocatalytic activity of DSSC devices, where CEs with large surface area nanostructures tend to show larger PCE values and a higher electrocatalytic activity of the DSSCs.²⁸² The DSSCs with TiS₂/graphene hybrids¹⁹⁹ and TiS₂/PEDOT:PSS composites²⁰⁰ based CEs showed environmental stability of up to 20 and 30 days, respectively, with no degradation in the photovoltaic performance. Interestingly, thermoelectric Bi₂Te₃ nanosheet/ZnO nanoparticles composite based photoanodes³³⁵ exhibited a 46.95% increase in PCE value compared with a bare ZnO photoanode based DSSC. Also, the DSSC with the Bi₂Te₃/TiO₂ composite based photoanode³³⁶ showed a 28% increase in PCE than that of pure TiO₂ photoanode.

Transition metal dichalcogenides (TMDs) based materials which are analogues of 2D graphene are emerging as a great alternative to fabricating low-cost Pt-free DSSC devices. TMDs-based CEs have demonstrated better electrochemical stability than that of standard Pt CE in iodine-based electrolyte and also under ambient conditions. In addition to long-term stability, TMDs may also cause cytotoxicity to humans, as has been observed for other nanostructured materials,^{378–383} therefore, aspects of toxicity should be investigated in studies with DSSC devices.

2D TMDs based CEs are a cheap alternative to Pt CE for DSSCs. In this review, we have summarized recent developments of TMDs used as CE materials for DSSCs which are still in their infancy. The low-cost 2D TMDs are abundantly available in nature, and can easily be processed into thin films and hybridized with other inorganic and organic materials for fabricating DSSC devices. The vast majority of 2D TMDs have yet to be studied, even as 2D graphene-based materials, but at this early stage they offer a low-cost alternative and outperform their Pt counterparts. Tremendous possibilities exist for developing new TMDs based CEs for I₃⁻/I⁻, Co²⁺/Co³⁺ and T₂/T⁻ redox couples. The important requirements for commercial applications are ease of processing, low-cost manufacturing, high PCE

value, and long-term electrochemical stability. Like graphene-based materials, more edge active sites can be created in TMDs-based CEs to facilitate more dye adsorption. Research on the use of TMDs CE are in very early stage of developing Pt-free DSSCs. TMDs based CEs offer increased charge transfer capability and fast reaction kinetics for the reduction of triiodide (I₃⁻) to iodide (I⁻) in electrolyte for DSSCs and their potential can be realized in parallel to graphene. The large family of TMDs, such as MoS₂, MoSe₂, MoTe₂, WS₂, WSe₂, WTe₂, FeSe₂, TaS₂, NbSe₂, *etc.*, should also be explored with other inorganic and organic materials, as the family of 2D materials is enormously large and are expected to play an important role in developing low-cost highly efficient DSSCs for commercial applications.
