## Structure of the caffeine–pyrogallol complex: revisiting a pioneering structural analysis of a model pharmaceutical cocrystal†‡

 Okba Al Rahal,<sup>id</sup><sup>a</sup> Michael Ferguson,<sup>id</sup><sup>a</sup> Cameron B. Lennox,<sup>id</sup><sup>ab</sup> Louise Male<sup>id</sup><sup>a</sup> and Tomislav Friščić<sup>id</sup><sup>\*ab</sup>

The 1967 attempt of structural analysis of the solid-state complex of caffeine and pyrogallol was a pioneering structural investigation in the supramolecular chemistry of caffeine, of what today would easily be considered an archetype of a model pharmaceutical cocrystal. Re-investigating this historically important system demonstrates that this long overlooked complex is most likely a tetrahydrate with a different structure and composition than initially proposed, and provides the crystal structure of the anhydrous cocrystal.

Cocrystals have emerged as a means to develop new materials, by modifying the solid-state environment and properties of molecules without disrupting their covalent structure.<sup>1</sup> Cocrystallisation has found particular value in controlling solid-state reactivity,<sup>2</sup> and the creation of materials with novel optical,<sup>3</sup> emissive,<sup>4</sup> electrical,<sup>5</sup> responsive and other behaviours.<sup>6</sup> Arguably the most important application of cocrystals is in pharmaceutical materials science, allowing the optimisation of diverse solid-state properties of active pharmaceutical ingredients (APIs).<sup>7</sup> The development of pharmaceutical cocrystals has heavily relied on model systems, such as commercial drugs, but also readily accessible molecules with functional groups typical of APIs. Among the latter, caffeine (**caf**, Fig. 1a) is among the most popular, providing a sandbox for exploring cocrystal design,<sup>8</sup> polymorphism,<sup>9</sup> moisture sensitivity,<sup>10</sup> nucleation,<sup>11</sup> screening methods,<sup>12</sup> formulation stability, *etc.*<sup>13</sup> The Cambridge structural database (CSD) contains > 330 **caf**-based structures, a testament to the popularity and importance of

**caf** in the structural science of organic solids.<sup>14</sup> Complexation of **caf** is a persistent topic of supramolecular chemistry in solution and the solid state, and has been attracting the attention of chemists, and pharmaceutical and food scientists for over 120 years.<sup>15,16</sup> Much groundbreaking work in **caf** complexation has focused on carboxylic acids,<sup>17</sup> notably the work of Higuchi in the 1950s,<sup>18</sup> and the earliest crystallographic report of a **caf** cocrystal in the CSD appears to be by Shefter, who in 1968 reported the structure of a complex with 5-chlorosalicylic acid: a pioneering entry of X-ray crystallography to understand **caf** complexation.<sup>19</sup>

Here, we revisit an even earlier attempt of crystallographic analysis of a solid-state **caf** complex, which appears to have remained largely overlooked. In a thesis published in 1967, followed by a subsequent 1968 report, Arnone and Marchessault described a hydrated cocrystal with pyrogallol (**pyg**, Fig. 1a), of composition **caf**·**pyg**·5H<sub>2</sub>O.<sup>20</sup> Whereas low data quality prevented reliable analysis (*R*-value > 0.5), the structure was proposed to consist of alternating **caf** and **pyg** layers, connected by hydrogen bonding with water molecules. Unexpectedly, a recent report outlined the structure of a hydrated cocrystal of composition 2**caf**·3**pyg**·2.5H<sub>2</sub>O, with crystallographic parameters very different from those of Arnone and Marchessault.<sup>21</sup> While the original 1967 work appears to have remained largely unknown to the crystal engineering community, its historical significance in pharmaceutical and food science as one of the earliest, if not the earliest, crystallographic explorations of the supramolecular chemistry of **caf**, and also a prototype of a model pharmaceutical cocrystal, mandate revisiting this system. We now show that the phase reported by Arnone and Marchessault is readily reproduced, but is in fact a tetrahydrate of a different structure than initially proposed, and report the previously not known anhydrate.

Cocrystallisation of **caf** and **pyg** was explored by ball-milling and by SpeedMixing,<sup>22</sup> *i.e.* rapid mixing in the presence of a liquid additive. Upon processing an equimolar mixture of **caf** and **pyg** in the presence of small amounts of nitromethane

**Fig. 1** (a) ORTEP view of the asymmetric unit of **caf-pyg**·4H<sub>2</sub>O, with non-hydrogen atoms shown as ellipsoids of 50% probability. Views of the crystal structure of **caf-pyg**·4H<sub>2</sub>O: (b) a single hydrogen-bonded column; (c) two disordered core chains, shown in ball-and-stick style and colored blue and black, surrounded by an envelope of water molecules shown in stick style; (d) two interwoven hydrogen-bonded **caf-pyg** helices and (e) repeat unit of a **caf-pyg** helix viewed along the crystallographic *c*-axis.

(MeNO<sub>2</sub>), both methods provided a material whose powder X-ray diffraction (PXRD) pattern was distinct from any of the starting materials or **caf** hydrate (see ESI†). Varying the amount of liquid (expressed as the ratio of liquid additive volume to weight of solid material,  $\eta^{23}$ ) enabled this material to be obtained free of any starting materials, as evidenced by PXRD. Recrystallisation of the product by slow evaporation of a solution in ethyl acetate (EtOAc) produced rod-shaped crystals suitable for single crystal X-ray diffraction. Crystallographic analysis revealed a tetragonal unitcell in space group  $P4_2/n$ , with parameters  $a = 23.1123(5)$  Å,  $c = 6.8449(2)$  Å. These measured crystallographic parameters are consistent with those reported ( $a = 23.26$  Å,  $c = 6.99$  Å) for tetragonal **caf-pyg**·5H<sub>2</sub>O by Arnone and Marchessault. Analysis, however, reveals that the structure and composition are significantly different from those proposed for **caf-pyg**·5H<sub>2</sub>O.

Most significantly, the crystal structure (Fig. 1) was found to be a channel hydrate with a tetrahydrate (**caf-pyg**·4H<sub>2</sub>O), rather than pentahydrate, composition. The asymmetric unit of

**caf-pyg**·4H<sub>2</sub>O contains a single molecule of **caf** and **pyg**, as well as four water molecules, with one being split equally over two mutually exclusive sites (oxygen atoms O9 and O9A, Fig. 1a). The water molecules arrange into columns extending along the crystallographic *c*-axis, exhibiting edge-fused hydrogen-bonded pentagons and heptagons (Fig. 1b, also ESI†). Each water column comprises a core helical chain of alternating, hydrogen-bonded O9- and O9A-based water molecules, surrounded by an envelope of other water molecules. The 50:50 disorder of O9 and O9A atoms, validated by periodic density-functional theory (DFT), results in two types of such core chains, identical in structure but offset by a helix half-turn (Fig. 1c, also ESI†). Each water column is further surrounded by helices of hydrogen-bonded alternating molecules of **caf** and **pyg**, again propagating in the *c*-direction (Fig. 1d). As a result of the centrosymmetric space group  $P4_2/n$ , the structure of **caf-pyg**·4H<sub>2</sub>O contains an equal number of left- and right-handed **caf-pyg** helices, as well as left- and right-handed O9···O9A hydrogen-bonded helices. The repeat unit of the **caf-pyg** helix is approximately rectangular in shape, and is based on O–H···N and O–H···O hydrogen bonds between 1,3-positioned –OH groups of each **pyg** with neighbouring **caf** molecules. The **pyg** molecules adopt a planar *anti*-conformation with only one intramolecular hydrogen bond.<sup>24</sup> In this conformation, the –OH group in the 2-position of **pyg** attaches the **caf-pyg** helix to the self-assembled column of water molecules *via* O–H···O bonds (Fig. 1e).

The formation of a **caf-pyg**·4H<sub>2</sub>O single crystal from EtOAc was not expected, as no water was added either during the synthesis of the bulk material or recrystallisation. Moreover, the PXRD pattern simulated for the **caf-pyg**·4H<sub>2</sub>O structure differs from that of the bulk material before recrystallisation from EtOAc, indicating that the formation of a hydrate crystal is due to moisture absorption during crystal growth.

The **caf-pyg**·4H<sub>2</sub>O was also accessible in bulk form, by SpeedMixing or ball milling in the presence of water (see ESI†). Specifically, milling at  $\eta = 0.25$  μL mg<sup>−1</sup> (corresponding to **caf-pyg** : H<sub>2</sub>O molar ratio of *ca.* 1 : 1 : 4.4) gave a material whose PXRD pattern, according to Rietveld refinement, was an excellent match to that simulated for **caf-pyg**·4H<sub>2</sub>O (see ESI†). Attempted indexing of the PXRD pattern gave a tetragonal unitcell with  $a = 23.165(4)$  Å and  $c = 6.944(1)$  Å, in agreement with the parameters for the herein reported **caf-pyg**·4H<sub>2</sub>O structure, and those previously noted for **caf-pyg**·5H<sub>2</sub>O. To validate whether the bulk material could fit to the previously proposed **caf-pyg**·5H<sub>2</sub>O model, we attempted to find the structure solution from PXRD data using DASH (see ESI†). Rietveld fitting of the three best simulated annealing solutions for the formula **caf-pyg**·5H<sub>2</sub>O gave unsatisfactory results, evidenced by significant residual features in the difference plot and poor  $R_{wp}$  (16–20%) and  $R_p$  (11–14%) indices (see ESI†). In contrast, Rietveld refinement of the herein reported **caf-pyg**·4H<sub>2</sub>O structure against bulk PXRD data gave a much better fit, with  $R_{wp} = 7.7%$  and  $R_p = 5.3%$ .

Simultaneous thermogravimetric and differential scanning calorimetry analysis (TGA/DSC, see ESI†) of the material

revealed a weight loss of *ca.* 18% in the range 22–60 °C, consistent with the formula **caf-pyg**·4H<sub>2</sub>O. The weight loss is accompanied by a broad endothermic event with a maximum at ~43 °C, followed by a sharper one at ~127 °C. Hot-stage microscopy (see ESI†) revealed that the weight loss step and the first endothermic signal are associated with sample liquefaction, which then solidifies and melts again. These observations suggest that heating of **caf-pyg**·4H<sub>2</sub>O leads to deliquescence and water loss, followed by crystallisation of an anhydrous phase. This agrees with TGA/DSC of the material prepared by milling or SpeedMixing with MeNO<sub>2</sub>, which revealed no weight loss before *ca.* 175 °C, indicating that it should be the anhydrous cocrystal **caf-pyg**. The DSC thermogram of this material exhibits a single, sharp endothermic event at ~127 °C, confirming the melting point of the anhydrous cocrystal. Overall, these observations show that the herein obtained hydrate, as well as the material described by Arnone and Marchessault, is a tetrahydrate of composition **caf-pyg**·4H<sub>2</sub>O.

Besides the difference in water content, the herein determined structure of the **caf-pyg** hydrate differs significantly from the previously proposed pentahydrate model. In the latter, the molecules of **caf** and **pyg** are not directly hydrogen-bonded, but occupy separate layers connected through hydrogen bonds to chains of water molecules.<sup>25</sup> One supramolecular aspect of the proposed **caf-pyg**·5H<sub>2</sub>O structure, however, matches the herein reported **caf-pyg**·4H<sub>2</sub>O structure: the orientation of  $\pi$ -stacked **caf** and **pyg** molecules in **caf-pyg**·4H<sub>2</sub>O corresponds well to that in the proposed pentahydrate model (see ESI†). A deeper comparison of **caf-pyg**·4H<sub>2</sub>O and the pentahydrate model was, however, not possible, as the poor data quality from the original report meant that even the geometries of the component molecules were distorted (see ESI†).

In order to directly compare the herein determined **caf-pyg**·4H<sub>2</sub>O and previously proposed **caf-pyg**·5H<sub>2</sub>O structures, we conducted a DFT optimisation using the PBE functional and D3 semi-empirical dispersion correction. Upon optimisation, the putative pentahydrate structure underwent significant (>15%) volume expansion. Detailed analysis of the optimised crystal structure also revealed a number of unusual characteristics, including the **pyg** molecule adopting an unusual conformation<sup>24</sup> with only one intramolecular hydrogen bond, the central hydroxyl moiety twisted outside of the molecular plane, as well as several water molecules involved in very long (>3 Å) O–H...O hydrogen bonds or engaging in hydrogen bonding through just one –OH group. Attempted Rietveld fitting of the optimised pentahydrate structure to the PXRD pattern of bulk **caf-pyg**·4H<sub>2</sub>O was unsuccessful (see ESI†,  $R_{wp}$  = 46.5% and  $R_p$  = 33.7%), reinforcing the view that the reported<sup>20</sup> pentahydrate complex of **caf** and **pyg** was the herein described **caf-pyg**·4H<sub>2</sub>O structure.

To explore if previous work<sup>20</sup> might have been dealing with another hydrated phase, the anhydrous **caf-pyg** was studied by dynamic vapour sorption (DVS, see ESI†), which revealed a reversible weight change step of 18.8%, consistent with gain or loss of four equivalents of water from **caf-pyg**·4H<sub>2</sub>O (calculated: 18.4%). Analysis of the PXRD pattern of bulk

**caf-pyg**·4H<sub>2</sub>O after the desorption step was consistent with complete transformation into anhydrous **caf-pyg** and, after exposure to 90% relative humidity (RH), it revealed complete conversion back to **caf-pyg**·4H<sub>2</sub>O. The PXRD pattern of an equimolar physical mixture of **caf** and **pyg** after exposure to 100% RH over 24 h revealed Bragg reflections consistent with **caf-pyg**·4H<sub>2</sub>O, **caf-pyg**, **pyg**·0.25H<sub>2</sub>O (CSD QQQBKD01) and **caf** hydrate (CSD CAFINE01), but no other solid forms of **caf** and/or **pyg**. Moreover, *in situ* PXRD monitoring of the thermal desolvation of **caf-pyg**·4H<sub>2</sub>O by heating in the range 20–100 °C revealed only the disappearance of Bragg reflections of **caf-pyg**·4H<sub>2</sub>O and the appearance of those of **caf-pyg** (see ESI†).

It is surprising that TGA/DSC, VT-PXRD and DVS experiments so far did not provide any indication of the recently reported **2caf-3pyg**·2.5H<sub>2</sub>O. Consequently, we attempted a targeted synthesis, by milling **caf** and **pyg** in the respective 2 : 3 stoichiometric ratio, with the addition of ~2.5 equivalents of water. After 20 minutes, this experiment yielded **caf-pyg**·4H<sub>2</sub>O, as seen by PXRD. Reducing the amount of water to *ca.* 1.7 equivalents, however, gave a mixture of **caf-pyg**·4H<sub>2</sub>O and **2caf-3pyg**·2.5H<sub>2</sub>O phases (see ESI†). These experiments indicate a strong preference for the formation of the **caf-pyg**·4H<sub>2</sub>O phase, even when the amount of water is low.

We have also determined the structure of the previously not reported anhydrous cocrystal of **caf** and **pyg** (Fig. 2). Single crystals of this anhydrous phase were produced by slow

Fig. 2 (a) ORTEP representation of the asymmetric unit of **caf-pyg**, with non-hydrogen atoms show as 50% probability ellipsoids; (b) view of the **caf-pyg** crystal structure, illustrating the hydrogen-bonded assembly of molecules; (c) hot-stage microscopy images of **caf-pyg**·4H<sub>2</sub>O, illustrating the liquefaction and recrystallisation (also see ESI†).

evaporation of a solution of the product of SpeedMixing from a chloroform and acetone mixture (see ESI†).

Structural analysis confirmed the composition **caf-pyg**, and the PXRD pattern simulated for the structure agreed with that of bulk **caf-pyg** (see ESI†). The structure of **caf-pyg** is monoclinic (space group  $P2_1/n$ ), and consists of tetrameric (**caf**)<sub>2</sub>(**pyg**)<sub>2</sub> units reminiscent of the MacGillivray synthon,<sup>26</sup> with the two *ortho*-neighbouring –OH groups of each **pyg** molecule forming O–H···N and O–H···O hydrogen bonds with imidazole and the C6-keto moieties of **caf** molecules, respectively, forming a R<sub>4</sub><sup>4</sup>(22) motif. The remaining –OH group on each **pyg** molecule forms a hydrogen bond to a keto group of a neighbouring (**caf**)<sub>2</sub>(**pyg**)<sub>2</sub> unit, resulting in layers parallel to the crystallographic (101) set of planes. In contrast to **caf-pyg**·4H<sub>2</sub>O, the **pyg** molecules in anhydrous **caf-pyg** adopt the most stable *syn1*-conformation,<sup>24</sup> with two intramolecular O–H···O hydrogen bonds.

In summary, we have re-investigated what is likely to be one of the earliest reported attempts of crystallographic analysis of a caffeine cocrystal. We show that the initially reported crystalline complex with pyrogallol and its associated crystallographic parameters are readily reproduced. Structure analysis, however, shows that the complex is actually a tetrahydrate of a caffeine cocrystal with pyrogallol, with the anhydrous form also reported here. The tetrahydrate crystal packing is different than initially proposed: whereas the original model anticipated that caffeine and pyrogallol would interact solely *via*  $\pi$ -stacking,<sup>25</sup> the herein reported structures show direct hydrogen bonding between the components. Beyond the historical relevance in caffeine complexation, which is an area of significance in the development of supramolecular chemistry and has attracted interest for over a century, we note that this is also a contribution to the still poorly developed understanding of caffeine complexation with polyphenols.<sup>14,27</sup>

The data supporting this article have been included as part of the ESI†. Crystallographic data in CIF format has been deposited with the Cambridge Structural Database (CSD), deposition codes CCDC 2344173 and 2344174.†

We are grateful to Prof. A. Arnone for valuable discussions and comments, and for the support of Leverhulme International Professorship (TF), NSERC Doctoral scholarship (CBL), University of Birmingham, and the BlueBEAR HPC service.
