This comprehensive review covers remediation, sensing, and energy storage, inspiring sustainable polyoxometalate innovations.

Polyoxometalates (POMs) are metal-oxide complexes with exceptional redox tunability, pseudocapacitive charge storage, and great structural versatility, making them ideal nanomaterials for environmental remediation. This review analyses the POM-based technologies for detection and treatment of air/water pollutants, surpassing conventional technologies that require harsh conditions for hard-to-remove contaminants such as refractory sulfur compounds.

Global pollution includes refractory sulfur compounds from fossil fuels, toxic gases in air, and heavy metals, dyes, and emerging contaminants in water, driving acid rain, smog, antibiotic resistance and ecosystem toxicity. POMs provide efficient oxidative desulfurization, photocatalytic dye/heavy metal removal, and multipollutant adsorption in POM-based hybrid materials. POM structures enable visible-light mineralization in low-input environments with less energy; benefits include scalable low-toxicity remediation, while metal leaching risks under extreme pH are mitigated by heterogenization.

Polyoxometalates in Environmental Remediation and Energy Storage

Ingrid Gregorovic^{a,b}, Nahid Lotfian^c, Ruhollah Khajavian^c, Sukanya Maity^{d,e}, Masoud Mirzaei^{c*}, Sib Sankar Mal^{e*}, Manuel Aureliano^{f,g*} and Annette Rompel^{a,b*}Received 00th January 20xx,
Accepted 00th January 20xx

DOI: 10.1039/x0xx00000x

Over recent decades, while environmental awareness and pollution control efforts have yielded localized improvements, ongoing industrial growth, rapid global population expansion, and escalating energy demands continue to drive significant global environmental pollution challenges. Polyoxometalates, a remarkable class of metal-oxide complexes, have recently emerged as promising compounds in the development of multifunctional materials for environmental pollutant removal, energy conversion and storage, and sensing. This review critically examines current research on their use for the removal of common toxic gases – such as H₂S, NO_x, and volatile organic compounds (VOCs) – from polluted air, as well as the elimination of various organic dyes, heavy metals, and pharmaceutical contaminants from wastewater. POMs have also gained recognition as adaptable redox-active materials suitable for next-generation energy storage systems. Their high electron-transfer capacity, structural flexibility, and remarkable chemical stability make them ideal candidates for various applications. POMs can facilitate multi-electron redox processes, allowing for their application in batteries, supercapacitors, and hybrid devices, which results in improved energy density and cycling performance. Recent developments in POM-based composites and electrode designs are further discussed for innovative, sustainable, and scalable energy storage solutions. Additionally, their tunable electrical and magnetic properties make them effective sensors for detecting various environmental pollutants.

1 Introduction

In recent times, rapid industrial and technological development has caused a significant increase in energy demand and environmental pollution (EP).^{1,2-3} The Encyclopaedia Britannica defines environmental pollution as the addition of any substance (solid, liquid, or gas) or any form of energy (such as heat, sound, or radioactivity) to the environment at a rate faster than it can be removed from the environment or stored in a harmless form. It further categorizes environmental pollution based on the affected medium into air, water, and land pollution.⁴ Increasing attention has been paid to the development of new methods for the removal of potential environmental pollutants¹⁻³ during industrial processes and

clean energy production.⁵ Although industrial development has brought many positive aspects to everyday life (e.g. new technology, better food safety and supply, medicines, etc.), it has also increased consumption and pollution of natural resources (water, soil and air)^{3,6}, which has become both an environmental problem and a health threat for the entire human population.⁷

The global shortage of clean water and the pollution of water resources pose critical health, economic⁸, and environmental challenges.⁹⁻¹¹ Especially in many underdeveloped and currently developing parts of the world, sewage wastewater and wastewater from different factories are discharged directly into the environment, causing catastrophic water pollution (Section 2; **Figure 1**) with hard-to-remove toxic chemicals – inorganic pollutants (Section 2.2) such as heavy metals (Section 2.2.1) and organic pollutants¹² (Section 2.3) such as organic dyes¹³ and solvents.¹⁴

The most prominent classes of health emerging pollutants (EPs)¹⁵⁻¹⁷ (Section 3; **Figure 1**) are pharmaceuticals¹⁸ (Section 3.1), pesticides and herbicides¹⁹ (Section 3.2), cosmetics^{20,21}, industrial and household products²², metals¹³ (Section 2.2), dyes¹³ and aromatic hydrocarbons (Section 2.3.2).²³ The presence of EPs in wastewater has been associated with the development of bacterial resistance^{20,24}, and mutagenicity and toxicity in aquatic organisms^{21,25} and humans.^{22,25}

Pesticides and herbicides (for their removal, see Section 3.2) are an inevitable part of the modern agricultural industry and food production.²⁶ However, in addition to ensuring yields and

protecting crops from pests, the widespread use of these chemicals also affects soil enzymes and microorganisms²⁶ crucial for many essential biological processes, such as N₂-fixation in plants by rhizobacteria.²⁷ The excessive use of pesticides also impacts wildlife, with a scientific focus on bees, birds, fish and small mammals.^{28–30} Human health is also affected by pesticide residues in the environment and food³¹ causing various health problems, such as cancer,^{32,33} endocrine disruption,³⁴ obesity,^{35,36} reproductive health issues, and birth defects.³⁷ Therefore, many Western countries (e.g. EU, USA) have introduced stricter controls and limitations³⁸ on the use and allowable levels of pesticide residues in food, water and soil.³¹

Fossil fuels continue to be one of the primary energy sources in today's world.³⁹ Their combustion (Section 4.1) produces various toxic refractory sulfur-containing compounds (dibenzothiophenes, DBTs)^{40,41} and gases (hydrogen sulfide⁴² (Section 4.2.1), nitrogen oxides (Section 4.2.2), and sulfur oxides (Section 4.2.2)⁴³, which cause different severe environmental issues such as global warming,⁴⁰ smog⁴⁴ and acid rains.⁴⁵ Toxic gases generated from traffic and flue gases from the industry have made poor air quality an important factor in causing respiratory^{46–48} and cardiovascular health⁴⁹ issues in urban areas.⁵⁰ Air purification (Section 4; **Figure 1**) using adsorption processes⁵¹ (Section 4.2) and desulfurization of fossil fuels⁵² (Section 4.1) is currently a logical approach to decreasing air pollution.

Global environmental pollution has escalated to crisis levels, driven significantly by fossil fuel combustion that releases refractory sulfur compounds such as dibenzothiophenes (DBTs), toxic gases including H₂S, NO_x, and SO₂, and emerging contaminants resistant to conventional treatment methods. These pollutants contribute directly to the formation of acid rain, smog, and severe health crises that impact billions worldwide.^{52,53–59} Conventional technologies like hydrodesulfurization (HDS) are ineffective against sterically hindered DBTs and require extreme conditions (300–400 °C, 30–100 bar H₂), while amine scrubbing and selective catalytic reduction (SCR) systems⁶⁰ face limitations in capacity, cost-efficiency, and simultaneous multi-pollutant management for air purification.^{53,61} Water faces persistent heavy metals, dyes, pharmaceuticals, and microplastics that evade standard filtration and oxidation.^{15,16,17,20,22,24,25} POMs offer a powerful, direct solution to these multifaceted challenges via mild-condition oxidative desulfurization achieving over 99% removal of refractory sulfur, versatile multi-pollutant adsorption and catalysis, and photocatalytic mineralization.^{62,63} Their uniquely tunable redox properties and acidity provide sustainable remediation options precisely where traditional technologies are insufficient.^{53,62}

The first step in combating pollution is building a good system to monitor and detect various harmful compounds present in the environment. In this regard, various materials have been extensively researched and designed to develop new chemical⁶⁴, electrochemical⁶⁵, and biosensors⁶⁶ (Section 5; **Figure 1**) for environmental monitoring. For example, metal or

metal oxide nanoparticles are widely used to develop various electrochemical sensors.^{67–69} DOI: 10.1039/D5EN00964B

New efficient technologies for energy conversion and storage need to be developed (Section 6; **Figure 1**) because renewable energy sources such as wind, hydroelectric, and solar power alone cannot meet the world's current energy demands.⁷⁰ In addition, the growing popularity and use of various portable electronic devices in everyday life have led to intensive research and development of new efficient battery technologies such as lithium-ion⁷¹, sodium-ion⁷², and redox-flow batteries.⁷³ Rechargeable Li-ion batteries and supercapacitors have been commercially utilized due to their ability to hold high energy with power density for various applications (e.g., electric vehicles, power tools, or portable/wearable electronic devices).^{74–76}

Figure 1. Schematic illustration of the main roles of polyoxometalates (POMs) in environmental remediation and energy storage. The central part emphasizes POM-based environmental remediation, while the surrounding segments show key applications, including pollutants detection, removal, sensing, treatment of (health) emerging pollutants, air pollutants and water contaminants, energy storage, energy conversion, and signalling.

1.1 Polyoxometalates

Polyoxometalates (POMs)⁷⁷ are a class of transition metal-oxide clusters, usually containing Mo or W ions in their highest oxidation states. They exhibit exciting and unique physical and chemical properties, such as controllable shape and size⁷⁷, oxo-enriched surfaces, photoactivity⁷⁸, molecular conductivity⁷⁹, excellent chemical stability, and redox properties⁸⁰. These properties have led to their increasing use in diverse fields, including catalysis^{81,82}, magnetism⁸³, medicine^{84,85}, biotechnology⁸⁶, protein crystallography^{87–89}, and material science⁹⁰.

POMs are typically synthesized via controlled acidification and condensation of simple metal oxoanions such as Mo^{VI}O₄²⁻, W^{VI}O₄²⁻, or V^{VO}O₄³⁻, which allows the precise formation of diverse structural archetypes, including some of the most common POM archetypes like Keggin (**Figure 1.F**), Wells-Dawson (**Figure 1.H**), and Anderson-Evans (**Figure**

1.I).^{76,77,91,92,93} Their functionality in pollutant removal is often enhanced by immobilization or hybridization⁹⁴, where POMs are incorporated into different solid supports like metal-organic frameworks (MOFs)^{95–105}, porous silica^{106,107}, graphene oxide (GO)^{108,109}, or polymeric supports^{94,110,111}, improving POM stability and catalytic efficiency.^{94,101,112} Ion exchange with organic or inorganic cations^{113,114,115}, surface modifications⁹⁴, or doping with lanthanide ions¹¹⁶ further tailor their physicochemical properties. Such synthetic versatility enables customization of POM-based materials to optimize catalytic, adsorptive, and photocatalytic performance in environmental remediation.^{94,101,117} The structural characteristics of polyoxometalates can be divided into two main general subgroups, isopolyoxometalates and heteropolyoxometalates.^{76,77} The isopolyoxometalates, with the general formula $[M_xO_y]^{n-}$ (where M = Mo, W or V; **Figure 2.A–D**), contain only addenda metals and oxygen atoms in their structure, such as Lindqvist^{118,119} ($[Mo_6O_{19}]^{2-}$; **Figure 2.A**), heptamolybdate^{120,121} ($[Mo_7O_{24}]^{6-}$; **Figure 2.B**), octamolybdate^{122,123} ($[Mo_8O_{26}]^{4-}$; **Figure 2.C**), decatungstate^{124,125} ($[W_{10}O_{32}]^{4-}$; **Figure 2.D**) and decavanadate^{126,127} ($[V_{10}O_{28}]^{6-}$; **Figure 2.E**). Heteropolyoxo species have the general formula $[X_zM_xO_y]^{n-}$ (X = heteroion, M = Mo, W or V, $z < x$, y = number of oxygen atoms in the POM structure, n = overall anion charge), where different heteroions X are present alongside addenda ions M and oxygen atoms. This composition allows them to form a variety of structural types, including common ones such as Keggin^{128,129} ($[XM_{12}O_{40}]^{n-}$; **Figure 2.F**), lacunary Keggin¹³⁰ ($[XM_{11}O_{39}]^{n-}$; **Figure 2.G**), Wells-Dawson^{131,132} ($[X_2M_{18}O_{62}]^{n-}$; **Figure 2.H**), Anderson-Evans^{133,134} ($[XM_6O_{24}]^{n-}$; **Figure 2.I**), Preyssler¹³⁵ ($[MP_5M_{30}O_{110}]^{(15-n)-}$; **Figure 2.J**), Strandberg^{136,137} ($[X_2Mo^V_5O_{23}]^{n-}$, (X = P^V, S^{VI}, As^V, Se^{VI}); **Figure 2.K**), Weakley^{138,139} ($[M^{III}(M^{VI}_5O_{18})_2]^{n-}$; **Figure 2.L**), among others. Moreover, if the POM solution is reduced, a unique class of giant molybdenum blue and molybdenum brown-type structures ($\{Mo_{154}\}$ and $\{Mo_{132}\}$) are formed.¹⁴⁰ For more detailed information on POMs structures and general synthetic procedures, the reader is referred to the reviews in reference 91, 92, 93, 141, and 142.

Pure POMs exhibit different solution behaviors across the wide pH range; some, like Wells-Dawson-type structures, maintain their structural integrity, while others, such as Keggin-type POMs, undergo monolacunarization under acidic conditions relevant to environmental remediation.^{143–145} Their high solubility in aqueous media presents significant challenges for their use in applications, including leaching during wastewater treatment and difficulties in catalyst recovery.¹¹³ While pure POMs often dissolve in aqueous media¹¹³, strategic heterogenization approaches⁹⁴, such as immobilization on mesoporous silica (SBA-15)^{106,107,146}, metal-organic frameworks (like UiO-66 and MIL-101)^{95–101}, and POM-supported ionic liquid phases (POM-SILPs)^{147,112}, address this issue. Such methods significantly reduce leaching to < 1 % after 10 cycles (Tables S1 and S2). These enable recyclability over 5–10 cycles with minimal activity loss (**Table S1**)^{148–151}. Nevertheless, challenges remain including potential metal cation leaching from POM-composites under prolonged extreme pH exposure and the

need for long-term stability studies under real environmental conditions. These heterogenized systems demonstrate > 95 % POM retention after multiple uses.⁶³

Keggin-type POMs (**Figure 2.F–G**) are the most widely studied POM archetype, representing an average of 77.6 % of all published articles, particularly in applications targeting environmental pollutant removal (approximately 69 %). This predominance in environmental applications surpasses that of Wells-Dawson (**Figure 2.H**; ~9 %), Anderson-Evans (**Figure 2.I**; ~9 %), Sandwich-type (**Figure 2.L**; ~5 %), isopolymolybdates (**Figure 2.A–E**; ~5 %), and other types of POMs (each ~5 %). In this review, Keggin-type POMs (**Figure 2.F–G**) are most frequently addressed in Section 3 (wastewater treatment, 75 %) and Section 4 (air pollutant removal, 85 %). Wells-Dawson type POMs (**Figure 2.H**) rank second in environmental pollutant removal (average 16.9 %), with their primary use found in sensing (75 %, Section 5). Notably, Section 4.1. showcases the broadest diversity of structural archetypes for POM-mediated fossil fuel desulfurization.

Isopolyoxometalates

Heteropolyoxometalates

Figure 2. Structures of isopolyoxometalates and heteropolyoxometalates: 1A) Lindqvist ($[Mo_6O_{19}]^{2-}$), 1B) heptamolybdate ($[Mo_7O_{24}]^{6-}$), 1C) 8-octamolybdate ($[Mo_8O_{26}]^{4-}$), 1D) decatungstate ($[W_{10}O_{32}]^{4-}$), 1E) decavanadate ($[V_{10}O_{28}]^{6-}$), 1F) Keggin ($[XM_{12}O_{40}]^{n-}$), 1G) monolacunary Keggin ($[XM_{11}O_{39}]^{n-}$), 1H) Wells-Dawson ($[X_2M_{18}O_{62}]^{n-}$), 1I) Anderson-Evans ($[XM_6O_{24}]^{n-}$), 1J) Preyssler ($[MP_5M_{30}O_{110}]^{(15-n)-}$), 1K) Strandberg ($[X_2Mo^V_5O_{23}]^{n-}$), and 1L) Weakley ($[M^{III}(M^{VI}_5O_{18})_2]^{n-}$). Color legend: orange = M (either Mo^VI , W^VI or V^V), blue = Mo^VI , purple = W^VI , yellow = V^V , gray = X (heteroion), white = M^{III} , and red = oxygen.

A literature search conducted on Web of Science in August 2025 (**Figure 3**) revealed that approximately 12 % (1928) of the

published articles on POMs related to the keyword “environment”, out of a total of 15830 articles. As of August 14, 2025, the number of articles varies by specific subject: the combination of “polyoxometalate” and “degradation” yielded 1306 articles, while “polyoxometalates” and “dyes” yielded 910 articles. These numbers exceed those for “polyoxometalate” combined with “pollutants” (353), “waste” (258), “industrial chemicals” (134), and “wastewater” (215). Fewer articles were found for combinations with “antibiotics” (98), “pesticides” (48), “fossil fuels” (40), and “air pollution” (26). The number of publications related to “antibiotics” and “wastewater” has more than doubled over the past 2 years, reflecting a marked increase in research interest in these areas.

In fact, the importance of POMs in environmental science and their relationship to sustainable development and green chemistry is clearly increasing. POMs are crucial in environmental science for their roles as catalysts and adsorbents, aiding in the degradation of emerging pollutants such as dyes, plastics, and antibiotics, in addition to well-known organic and inorganic contaminants^{152–160}. Moreover, POMs can act as novel antibacterial agents for water purification¹⁶¹. As described in the sections below, POMs are also fundamental for sustainable development by enabling energy applications such as solar hydrogen production and energy storage^{70–76}. Recent studies further explore POMs as electrochemical sensors for the simultaneous detection of inorganic heavy metal ions and organic antibiotic contaminants in aquatic environments¹⁶², and as triboelectric nanomaterials for gait monitoring¹⁶³.

Figure 3. Number of articles containing the term “polyoxometalate” combined with keywords such as dyes, pollutants, industrial chemicals, wastewater, pesticides, and antibiotics, as of August 14, 2025.

2 Water decontamination by polyoxometalates

Inorganic contaminants (Section 2.2) enter the environment as inorganic salts, mineral acids, sulfates, cyanides, and metal ions,

including heavy and radioactive metals. These contaminants are generally more persistent and more difficult to eliminate than organic ones.^{164,165} On the other hand, organic contaminants (Section 2.3) represent a more diverse class, consisting of organic dyes, aromatic hydrocarbons, pesticides, and pharmaceuticals (see Section 3 for pharmaceutical and pesticide removal). Due to rapid industrial development, large amounts of industrial, sewage, and agricultural waste discharged into water bodies cause organic pollutants to become pseudo-persistent in the ecosystem.^{166,167} Therefore, the removal of this class of contaminants requires careful consideration to move toward a sustainable ecosystem.

As discussed in Section 2.1, oxidation, catalysis, photocatalysis, ion-exchange, adsorption, and membranes are among the commonly used technologies for the removal of these pollutants due to their high efficiency, cleanliness, and simple operation. POMs have shown promise in mitigating the global water purification issue using the above-mentioned technologies. This section covers novel solutions by highlighting recent achievements in designing multi-component materials for use in water-purification systems.

2.1 Emerging pollution treatment technologies

Water treatment is a multi-stage process, comprising several stages with various technologies. Tertiary treatment is the final stage of the multi-stage wastewater treatment process. It is used after preliminary stages, and commonly used techniques utilized for the treatment include oxidation, photocatalysis, ion exchange, adsorption, and membranes technology (Figure 4).¹⁶⁸ Chemical oxidation is a cost-effective and simple technology for the decontamination of both organic and inorganic pollutants using an oxidizing agent such as chlorine, hydrogen peroxide, ozone, and molecular oxygen. In advanced oxidation processes (AOPs), POMs (especially iron-containing POMs) have been used as efficient catalysts for the decomposition of the oxidizing agent (H₂O₂) and removal of organic pollutants.¹⁶⁹ In particular, POMs can initiate the activation through electron transfer to H₂O₂ (originating from the redox property of the addenda atoms) or *via* formation of peroxo complexes.^{147,170} This method, however, may produce secondary pollutants that are formed after the initial oxidation. This may cause a decrease in the catalyst selectivity, while increasing the costs.

In photocatalysis, the ability of the catalyst to harvest photons from a light source and to generate free radicals to undergo photocatalytic oxidation or reduction reactions is crucial. In this regard, POMs have shown promise since i) their band gap value can be adjusted by changing the heteroatoms or adjusting the valence states of addenda atoms, and ii) they can store multiple electrons in one molecule; thus they exhibit fast charge transfer properties.^{171,172} Due to some drawbacks associated with pure POMs (*e.g.*, limited light absorption, high solubility), they are often employed in the form of hybrids or composites.¹¹² In these structures, the intermolecular interactions between two species can improve the stability and promote the lifetime of photogenerated charge carriers. In this regard, the incorporation of noble

metals,^{173,174} metals from the lanthanide series,¹⁷⁵ metal oxides,¹⁷⁶ metal-organic frameworks¹⁷⁷ and metal-free species¹¹⁰ have been reported to be effective.

Figure 4. Summary of tertiary treatment technologies used against inorganic and organic pollutants for water purification.

Ion exchange water purification technology relies on the availability of exchange surfaces with accessible specific surface area and the ability to reversibly uptake/release ions from water. POMs can fulfill some of these requirements. For example, their diverse topology, high negative charge, and redox properties of POMs have turned them into potential candidates for cation (heavy metal) uptake and exchange. However, POMs lack a high surface area that is problematic.¹¹³ Adsorption-based protocols have been extensively used for wastewater treatment on the account of cost, simplicity, and energy considerations. The concept of this approach is based on removing pollutants by promoting their adsorption on the adsorbent surface *via* physical or chemical interactions.¹⁷⁸ In this context, some intrinsic properties of POMs (*e.g.*, high negative charge, strongly basic oxygen surfaces) are advantageous for the physis/chemisorption of adsorbate molecules. However, when considering POMs as water purifiers, some limitations such as their high solubility and the low surface area must be taken into consideration. The heterogenization of POMs by inorganic substrates^{106,107,179} or organic matrices^{111,179,180} is the common approach to solve their solubility issue and low specific surface area. In heterogenization with organic matrices, the surface chemistry of the matrix plays an important role. Along with the degree of POM dispersion and matrix morphology, it can enhance the physicochemical properties and improve the membrane's performance. Heterogenization by porous coordination polymers (MOFs) is another successful strategy that combines both the merits of POMs and MOFs (*e.g.* recyclability and porosity).^{95–101} This strategy is commonly used for the adsorptive removal of cationic dyes.^{102–105} However, the catalytic activity of POM composites greatly depends on their structural properties. In some cases, as for POM@MOF composites, the activity is mainly governed by pore-dependent diffusion limitation, where the match of pore aperture and POM diameter is essential.¹³⁹ Meanwhile, each individual structural component can also induce different electron transfer kinetics due to its unique electron-storage/transfer capacity.^{181,182}

Controlled deposition of POMs on substrates is another concept that enables the fabrication of POM-based functional devices for water purification.⁹⁴ Techniques such as layer-by-layer assembly, casting, and dip-coating have been recently reported.^{183–185}

Membrane filtration is a reliable, and environmentally friendly process with relatively low cost and simple operation, which has been widely used for water purification. Catalytic membranes represent a new generation of membranes created by incorporating inorganic particles, such as POMs, into a polymer matrix to enhance the membrane's (photo)catalytic properties.^{186–189} As a convincing demonstration of this approach, Yao *et al.* designed and fabricated an amine-functionalized APTMS-treated PEI membrane for dye removal from wastewater. $[\text{PV}^{\text{V}}_2\text{Mo}^{\text{VI}}_{12}\text{O}_{40}]^{5-}$ was incorporated into the matrix *via* a simple sol-gel protocol. The presence of $[\text{PV}^{\text{V}}_2\text{Mo}^{\text{VI}}_{12}\text{O}_{40}]^{5-}$ in the membrane not only enhanced the mechanical strength of PEI but also catalyzed the degradation of RB5 in the presence of a diluted solution of an oxidant (**Figure 5**).¹⁹⁰ The presence of different POM species was reported to be necessary for the self-cleaning property of the membrane.¹⁸³

Figure 5. Illustration of a POM-integrated catalytic membrane for organic dye decontamination from water. Reproduced from Ref. 190 with permission from Elsevier, Copyright 2016.

2.2 Removal of inorganic pollutants

2.2.1 Removal of heavy metals. Catalysis and photocatalysis are appropriate strategies for removing reductive toxic metal ions

from water.^{108,191,192} Gong *et al.* demonstrated that different highly reduced molybdophosphate hybrid materials such as $\{Co^{II}[P^V_4Mo^V_6O_{31}]_2\}^{n-}$ ($X = O$ or OH)¹⁹³ or $\{Mn^{II}[P^V_4Mo^V_6O_{31}]_2\}^{194}$ clusters could act as efficient heterogeneous catalysts for the reduction of toxic Cr(VI) to nontoxic Cr(III) in the presence of formic acid as the reducing agent under mild conditions. These noble metal-free POM catalysts have great potential to replace high-priced Pt/Pd catalysts for the elimination of Cr(VI) from water.

POMs or their modified derivatives, acting as electron reservoirs, have demonstrated efficiency in photoactivity, especially in visible light photocatalysis. Therefore, there is continuous effort to design a POM-based photocatalyst that can utilize solar energy for the reduction of highly toxic Cr(VI). Due to the good photocatalytic response of Ag-based photocatalysts, Wang's group heterogenized $H_3[PMo^{VI}_{12}O_{40}]$ with Ag^+ counter cations.¹⁹⁵ $Ag/Ag_xH_{3-x}PMo^{VI}_{12}O_{40}$ nanowires were synthesized by a facile solid-state reaction route and in situ photodeposited method. The resulting $Ag/Ag_x[H_{3-x}PMo^{VI}_{12}O_{40}]$ ($Ag/AgHPMo_{12}$) nanowires, where x denotes the irradiation time ($x = 2, 4, 6, 8$ h, respectively), showed higher stability and photocatalytic activity than traditional Ag-based photocatalysts (*e.g.* Ag/AgX ($X = Cl, Br, I$), $AgPO_4$ or $AgVO_3$)^{196–199} for Cr(VI) reduction. This is attributed to their good visible-light absorption and reversible redox properties of the Keggin-type POM (**Figure 2.F**). In addition, a part of the Ag^+ in the nanowires was *in situ* photoreduced to Ag NPs under visible light irradiation, and these Ag NPs enhanced visible-light absorption and the charge separation of photogenerated electrons (e^-) and holes (h^+) in $Ag/[AgHPMo^{VI}_{12}]$. In order to improve the catalytic efficiency of $Ag/[Ag_xH_{3-x}PMo^{VI}_{12}O_{40}]$ nanowires, these Ag-loaded 1D silver POM nanowires were well dispersed on duplicated 2D graphite-like carbon nitride ($g-C_3N_4$) nanosheets.²⁰⁰ The obtained $[Ag_xH_{3-x}PMo^{VI}_{12}O_{40}]/Ag/g-C_3N_4$ (x represents the irradiation time; $x = 2, 4$, and 6 h, respectively) 1D/2D Z-scheme heterojunction photocatalyst exhibited excellent and durable photocatalytic performance towards the reduction of Cr(VI), methyl orange (MO) and tetracycline (TCY) under visible light.²⁰⁰

In attempts to obtain efficient photocatalysts based on inorganic-organic hybrid POMs, a series of $[Ag_4(H_2O)(L)_3(SiW^{VI}_{12}O_{40})]$, $[Zn(L)(H_2O)_2(SiW^{VI}_{12}O_{40}) \cdot 3H_2O]$, $[Cu(L)(H_2O)_2(SiW^{VI}_{12}O_{40})]$, and $[Cu_2(L)_2(HPW^{VI}_{10}W^{V}_{2}O_{40}) \cdot 4H_2O]$ ($L = 1,4$ -bis(3-(2-pyridyl)pyrazole)butane), have been synthesized.²⁰¹ Interestingly, $[Ag_4(H_2O)(L)_3(SiW^{VI}_{12}O_{40})]$ (1) hybrid was able to act as an efficient photocatalyst to reduce Cr(VI) using the scavenger isopropanol under visible light at ambient temperature. In comparison with $[Ag_4(H_2O)(L)_3(SiW^{VI}_{12}O_{40})]$, the three other POM hybrids showed relatively weak photocatalytic activity. In a possible reduction mechanism of Cr(VI) to Cr(III), first, the $[Ag_4(H_2O)(L)_3]^{4+}$ unit was excited under visible light, and the excited state electrons on the organic ligand were inclined to transfer to the $[Ag_4(H_2O)(L)_3(SiW^{VI}_{12}O_{40})]$ POM. Simultaneously, the isopropanol on the surface of the hybrid yielded reducing radicals and captured the photoinduced holes produced by the hybrid photocatalyst. Finally, the isopropanol scavenged the

photoinduced holes and formed CO_2 , H_2O , and other products. This charge transfer maintains the recombination of holes and electrons. The electrons accumulated on $[Ag_4(H_2O)(L)_3(SiW^{VI}_{12}O_{40})]$ were responsible for reducing Cr(VI). It was concluded that the much larger $[Ag_4(H_2O)(L)_3]^{4+}$ metal-organic unit, in comparison to the other metal-organic units presented in other above-mentioned inorganic-organic hybrids, is probably responsible for the higher photocatalytic activity of the $[Ag_4(H_2O)(L)_3(SiW^{VI}_{12}O_{40})]$ compared to the other three compounds.²⁰¹ Adsorption is the other most used purification technique to remove heavy metals from wastewater. In order to prepare a multi-functional composite, Herrmann *et al.*⁶³ used a combination of lacunary Keggin anions $[\alpha-SiW^{VI}_{11}O_{39}]^{8-}$ and tetra-*n*-alkyl ammonium cations ($(n-C_6H_{13})_4N^+$ and $(n-C_7H_{15})_4N^+$) to prepare a highly viscous, lipophilic POM-IL complex, which was then immobilized on porous silica to give POM-SILP.¹⁶⁵ Each component of the POM-SILP composite contributed to the removal of a specific type of water contaminant. The lacunary Keggin tungstate anions (**Figure 2.G**) were responsible for metal-ion binding, whereas the long-chain quaternary organo-ammonium cations²⁰² acted as an antimicrobial. In addition, the POM-IL lipophilicity enabled the adsorption of organic contaminants, and the silica support bound radionuclides. Thus, using the water-insoluble POM-SILP composite in filtration columns allowed the simultaneous removal of toxic heavy metals (as Ni^{2+} , Pb^{2+} , Cu^{2+} , Cr^{3+} and Co^{2+}), microbes (*E. coli*), organic aromatics (trityl dye), and nuclear waste (UO_2^{2+}) from water (**Figure 6**).⁶³

Figure 6. Water purification using POM-SILPs: the POM-SILP column filter removes toxic heavy metals (*e.g.* Ni^{II} , Pb^{II}), UO_2^{II}), microbes (*E. coli*), and aromatic organic pollutants (*e.g.* trityl dyes) due to the presence of lacunary polyoxometalate anions with specific metal-binding sites (yellow arrow) and antimicrobial tetra-alkyl ammonium cations. Reproduced from Ref. 63 with permission from Wiley-VCH, Copyright 2017.

The highly hydrophobic nature of POM-IL leads to surface heterogeneity and thus facilitates biphasic removal of metal ions from aqueous solutions. At the same time, the negative charge present on the POM units is the driving force for the removal of metal ions with a positive charge. In order to increase the removal of heavy metals from water by POM-IL, Shakeela and Rao synthesized a series of Keggin-based ionic liquids by reacting in situ generated first-row transition-metal ion (Mn^{2+} , Fe^{3+} , Co^{2+} , Ni^{2+} , Cu^{2+} , and Zn^{2+}) substituted monolacunary Keggin with tetraoctylammonium (TOA) cations.²⁰³ Metal-substituted lacunary POMs carried a relatively higher negative charge which facilitated the absorption of metal cations. Thus, all these thermoreversible POM-ILs effectively

removed Cd^{2+} and Pb^{2+} metal ions from the aqueous phase.²⁰³ Embedding POM-ILs with tri-lacunary Keggin [$\alpha\text{-PW}^{\text{VI}}_9\text{O}_{34}$]⁹⁻ featuring coordinative binding of up to six metal cations into 3D printed organic polymers²⁰⁴ has been shown to produce a highly porous organic-inorganic composite for effective transition-metal removal (Figure 7).²⁰⁵

Cation exchange is another process for the removal of various metal cations from water. Synthetic inorganic ion exchangers with well-defined chemical and phase compositions appear to be the most suitable ones compared to organic ion exchangers due to higher thermal and chemical stability and higher exchange capacity and selectivity for a wide range of metal ions.¹¹³ For example, Cronin's group designed an inorganic open framework nanocube-based $\text{K}_{18}\text{Li}_6[\text{Mn}^{\text{II}}_8(\text{H}_2\text{O})_{48}\text{P}_8\text{W}^{\text{VI}}_{48}\text{O}_{184}]\cdot 108\text{H}_2\text{O}$, from highly anionic crown-type POM ($[\text{P}_8\text{W}^{\text{VI}}_{48}\text{O}_{184}]^{40-}$) and Mn^{II} as linkers to accommodate Cu^{II} cations from a solution into the network of channels and cavities. The cation-exchange capacity and rate are controlled by oxidizing the Mn linkers from +II to +III.²⁰⁶ In some cases, POM-IL systems exhibited greater efficiency than conventional ion-exchange resins.²⁰⁷

Figure 7. Schematic illustration of the POM-modified 3D-printed copolymer substrates used for transition-metal removal by the cation binding sites of the lacunary [$\alpha\text{-PW}^{\text{VI}}_9\text{O}_{34}$]⁹⁻. 2.2.2 Removal of radioactive metals. Although metal-organic frameworks (MOFs) initially exhibited a unique performance for the adsorptive removal of metal ions, most of these materials have low stability in aquatic media, which has limited their applications for water purification. To improve the stability of MOFs, Zou *et al.* functionalized HKUST-1 MOF with Keggin-type POM [$\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}$] POM (Figure 2.F) to form HKUST-1@[$\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}$] under microwave conditions. It was proposed that the improved water stability of HKUST-1@[$\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}$] was the result of POMs being encapsulated into HKUST-1 pores. The HKUST-1@[$\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}$] showed high adsorption affinity and capacity towards selective adsorption of heavy metal ions (highly selective for Pb^{2+} and Cd^{2+} , but no adsorption of Hg^{2+})

from contaminated water.²⁰⁸ Studies on HKUST-1@[$\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}$] adsorption ability to remove U(VI) from wastewater showed that it could selectively adsorb U(VI) from low concentration uranium solutions in the presence of other metal ions.²⁰⁹ The adsorption capacity of HKUST-1@[$\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}$] was strongly pH dependent and did not significantly decrease after three adsorption-desorption cycles. The presence of phosphate groups in the adsorbent structure has a great affinity for radioactive U(VI) ions in an aqueous solution.^{210,211} In this regard, a ship-type nano-cage POM $\{[\text{C}_5\text{NH}_5]_9[\text{H}_{31}\text{Mo}^{\text{VI}}\text{V}_{12}\text{O}_{24}\text{Co}^{\text{II}}_{12}(\text{PO}_4)_{23}(\text{H}_2\text{O})_4]\}^{2-}$ (Co-POM) with 23 $\{\text{PO}_4\}$ groups was designed and synthesized. The high adsorption capacity of this POM-based inorganic framework for U(VI) ions in aqueous solution was mainly ascribed to coordination interaction between U(VI) and O in the phosphate groups on Co-POM which was proved by FT-IR and XPS analyses.²¹² Composites of POMs ($\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}$) with graphene oxide also exhibited a significant potential for uranyl uptake from wastewater.¹¹³

The cation exchange studies by POMs have been widely used to separate radioactive metal ions from radioactive wastes.¹⁰⁹ Kortz's group worked on a cyclic K^+ -templated POM, $[\text{K}\{(\beta\text{-As}^{\text{III}}\text{W}_8\text{O}_{30})(\text{W}^{\text{VI}}\text{O}(\text{H}_2\text{O}))\}_3]^{14-}$, which showed high selectivity to Rb^+ , due to the relatively large size of the central cavity for K^+ (Figure 8).¹¹⁴ Uchida's group combined the Keggin cluster $[\text{SiMo}^{\text{VI}}_{12}\text{O}_{40}]^{4-}$ anions with a cationic oxo-centered trinuclear complex, to produce ionic crystals with isolated pores, $(\text{etpyH})_2[\text{Cr}_3\text{O}(\text{OOCH})_6(\text{etpy})_3]_2[\text{SiMo}^{\text{VI}}_{12}\text{O}_{40}]\cdot 3\text{H}_2\text{O}$ (etpy = 4-ethylpyridine), which selectively adsorbed Cs^+ among alkali and alkaline earth metals *via* reduction of the Keggin $[\text{SiMo}^{\text{VI}}_{12}\text{O}_{40}]$ with ascorbic acid.²¹³ The previously reported ionic crystal, $(\text{mepyH})_2[\text{Cr}_3\text{O}(\text{OOCH})_6(\text{mepy})_3]_2[\text{PMo}^{\text{VI}}_{12}\text{O}_{40}]\cdot 5\text{H}_2\text{O}$ (mepy = 4-methylpyridine, $\text{mepyH}^+ = 4\text{-methylpyridinium ion}$), with 1D open channels, was able to incorporate Na^+ as well as Cs^+ by the reduction-induced cation exchange processes.¹¹⁵ The authors concluded that the high selectivity towards Cs^+ is due to the existence of closed pores rather than open channels. Despite the high selectivity towards Cs^+ however, several disadvantages such as the requirement of heating (343 K) and slow adsorption kinetics (12 h to reach equilibrium) limited the widespread application of

$(\text{mepyH})_2[\text{Cr}_3\text{O}(\text{OOCH})_6(\text{mepy})_3]_2[\text{PMo}^{\text{VI}}_{12}\text{O}_{40}]\cdot 5\text{H}_2\text{O}$. Later, this group overcame disadvantages by utilizing the large-molecular size and easily reducible Wells-Dawson-type of POMs $[\text{P}_2\text{M}^{\text{VI}}_{18}\text{O}_{62}]^{6-}$ ($\text{M} = \text{Mo}, \text{W}$).²¹⁴ In comparison with the Keggin-type POM, the larger molecular size and higher reduction potential of Dawson-type POM increased the pore volume and facilitated the reduction-induced Cs^+ exchange. As expected, the capacity and rate of Cs^+ uptake increased significantly (with only 1 h to reach equilibrium at room temperature), demonstrating the potential application of these adsorbents for radioactive Cs^+ (Cs-137) removal.²¹⁴

Figure 8. Structure of $[M\{(\beta\text{-As}^{\text{III}}\text{W}_8\text{O}_{30})(\text{WO}(\text{H}_2\text{O}))_3\}]^{14-}$ with the central guest being either K^+ or Rb^+ . Color code: WO_6 (violet octahedra), As (orange), K/Rb (grey).¹¹⁴

2.3 Removal of organic pollutants

2.3.1 Removal of organic dyes. As shown in Table S2 (Supporting Information), the decontamination mechanisms, in the case of organic pollutants, are similar to previously discussed methods for inorganic ones. Adsorption of dye molecules, especially cationic ones, by POMs is strongly governed by solution pH. The selective adsorption of methylene blue (MB) in the presence of methyl orange (MO) over $[\text{P}_2\text{W}^{\text{VI}}_{18}]/\text{MOF-5}$ catalyst is spontaneous and endothermic. In addition, the pH value of dye solution should also be carefully controlled to obtain maximum adsorption capacity, because the surface charge of the adsorbent is strongly affected by the pH (pH_{PZC} ; PZC = point-of-zero charge).²¹⁵ Furthermore, olation and oxolation processes are responsible for the high negative charge on the POM surface at lower pH values.²¹⁶

In a generally accepted approach, photooxidation of dye molecules occurs through generation of free $\text{OH}^\bullet$. The proposed mechanism is based on the photoexcitation of $\text{Cs}_4\text{SiW}^{\text{VI}}_{12}\text{O}_{40}$ POM and a subsequent hydrogen abstraction reaction which results in the homolytic bond cleavage of H_2O . The photocatalytic activity of POMs, such as $[\text{SiW}^{\text{VI}}_{12}\text{O}_{40}]^{4-}$, can be enhanced in the presence of semiconductors. In fact, in such heterojunction structures with suitable energy band alignment, photogenerated carriers could be separated more efficiently.²¹⁷ Dye sensitization is another mechanism that may contribute to dye degradation in photocatalytic reactions. Due to the visible-light absorption abilities of the sensitizers, dye-sensitized POM photocatalysts can be excited upon visible-light irradiations. In these cases, the oxidation of dye proceeds through electron transfer between the excited dye (e.g., thionine, phthalocyanine) and LUMO of Keggin ($[\text{PW}^{\text{VI}}_{12}\text{O}_{40}]^{3-}$)^{218,219} or Wells-Dawson-type ($[\alpha\text{-P}_2\text{W}^{\text{VI}}_{18}\text{O}_{62}]^{6-}$ (P_2W_{18}) and $[\alpha\text{-P}_2\text{W}^{\text{VI}}_{17}\text{O}_{61}]^{10-}$)²¹⁸ type POMs.^{218,219}

As an interesting example of membrane filtration technology, Yao *et al.*¹⁷⁹ incorporated surfactant-encapsulated POM microparticles into a PVDF matrix as a microfiltration membrane for the adsorptive removal of the anionic dye Reactive Black 5 (RB5). The authors prepared spherical microparticles through an ion exchange reaction between a cationic surfactant (DODA-Br) and $[\text{PV}^{\text{V}}_2\text{Mo}^{\text{VI}}_{10}\text{O}_{40}]^{5-}$. This architecture enhanced the flow rate of the system and dye removal efficiency reached up to 97.5 % within 120 min.¹⁷⁹ A similar concept has been applied in the case of surface-active ionic-liquid-encapsulated POMs.²²⁰ Ion exchange reaction has also been used to replace small anions in the structure of layered double hydroxides (LDHs) with large polyanions. By this method the surface area of the resulting composite can be enhanced, since the interlayer distances of LDH increase. These composites have been used for the removal of cationic dyes from water; however, the instability of LDH in acidic media may limit their application.^{221,222} In 2005 Zhao and co-workers suggested that an active peroxy species is responsible in the photo-Fenton oxidation of Rhodamine B (RhB) under visible light irradiation. The authors proposed that the active species is formed upon the interaction of reduced POM with H_2O_2 .²²³ Similarly, in Fenton systems the active species is formed by the coordination of iron to $[\text{PW}^{\text{VI}}_{12}\text{O}_{40}]^{3-}$ POM.²²⁴ In Fenton-like systems the iron species is replaced with different POMs, like mentioned Keggin²²⁴ or $[\text{HPW}^{\text{VI}}_4\text{W}^{\text{VI}}_8\text{O}_{40}]^{6-}$ POMs.²²⁵ The radical-based pathways, however, can enhance apparent degradation rate if not properly identified or controlled. Among different transition metals (Co, Ni, Cu), Co-substituted Wells-Dawson anions $[\alpha\text{-P}_2\text{W}^{\text{VI}}_{17}\text{CoO}_{61}]^{8-}$ exhibited higher catalytic performance.²²⁶ Li's group prepared two POMCPs, $[\text{Ag}_4(\text{H}_2\text{pyttz-II})(\text{H}_2\text{pyttz-II})(\text{Hpyttz-II})][\text{HSiW}^{\text{VI}}_{12}\text{O}_{40}] \cdot 4\text{H}_2\text{O}$ ($\text{H}_2\text{pyttz-I} = 3\text{-(pyrid-2-yl)-5-(1H-1,2,4-triazol-3-yl)-1,2,4-triazolyl}$) and $[\text{Ag}_4(\text{H}_2\text{pyttz-II})(\text{Hpyttz-II})_2][\text{H}_2\text{SiW}^{\text{VI}}_{12}\text{O}_{40}] \cdot 3\text{H}_2\text{O}$ ($\text{H}_2\text{pyttz-II} = 3\text{-(pyrid-4-yl)-5-(1H-1,2,4-triazol-3-yl)-1,2,4-triazolyl}$) with similar structure and different tunnels (Figure 9a). The photocatalytic degradation of methylene blue (MB) demonstrated that the structure of the hybrids influences the photocatalytic properties. The larger cavities in the compound and $[\text{Ag}_4(\text{H}_2\text{pyttz-II})(\text{Hpyttz-II})_2][\text{H}_2\text{SiW}^{\text{VI}}_{12}\text{O}_{40}] \cdot 3\text{H}_2\text{O}$ increase the contact area between catalysts and crude materials and promote more active sites to participate in the reactions process. Thus, the photocatalytic properties of $\text{Ag}_4(\text{H}_2\text{pyttz-II})(\text{Hpyttz-II})_2][\text{H}_2\text{SiW}^{\text{VI}}_{12}\text{O}_{40}] \cdot 3\text{H}_2\text{O}$ were improved. The proposed mechanism for enhanced photocatalytic activity in these hybrids is shown in Figure 9b. This mechanism includes LMCT from the HOMO to the LUMO, which was facilitated by Ag–O bridging units. In addition to this, Ag-pyttz acted as photosensitizers and promoted the transition of electrons onto $[\text{SiMo}^{\text{VI}}_{12}\text{O}_{40}]^{4-}$ POMs. Therefore, the $[\text{SiMo}^{\text{VI}}_{12}\text{O}_{40}]^{4-}$ POMs had

a higher charge density and exhibited a considerable impact on the photocatalytic degradation of RhB.²²⁷

Figure 9. a) Representation of the $[\text{Ag}_4(\text{H}_2\text{pyttz-II})(\text{H}_2\text{pyttz-II})(\text{Hpyttz-II})][\text{HSiW}_{12}\text{O}_{40}]$ and $[\text{Ag}_4(\text{H}_2\text{pyttz-II})(\text{Hpyttz-II})_2][\text{H}_2\text{SiW}_{12}\text{O}_{40}]$ compounds ($\text{H}_2\text{pyttz-I} = 3\text{-(pyrid-2-yl)-5-(1H-1,2,4-triazol-3-yl)-1,2,4-triazolyl}$ and $\text{H}_2\text{pyttz-II} = 3\text{-(pyrid-4-yl)-5-(1H-1,2,4-triazol-3-yl)-1,2,4-triazolyl}$) with similar underlying frameworks and different tunnels. b) Representation of the photocatalytic mechanisms for POMCPs. Reproduced from Ref. 227 with permission from The Royal Society of Chemistry, Copyright 2015.

2.3.2 Removal of aromatic hydrocarbons. The oxidative potential of POMs has been broadly used in AOPs for phenol oxidation.²²⁷ For example, $[\text{PW}_{11}\text{O}_{39}\text{Fe}^{\text{III}}(\text{H}_2\text{O})]^{4-}$ can degrade chlorophenol (CP) compounds only if H_2O_2 is added to the solution. No photocatalytic activity was observed in aerated aqueous solution. In addition, the reaction rate was influenced by the initial concentration of the catalyst or H_2O_2 and the number of chlorines in the aromatic ring of CP.¹⁶⁸ Iron-containing POMs have also been used to construct heterojunction photocatalysts by grafting Fe-POM nanoclusters onto oxygen-deficient TiO_2 . The synergistic effect between photocatalysis and Fenton-like reactions resulted in efficient degradation of sulfosalicylic acid (SSA).²²⁸ Deposition of Au NPs on the surface of POM/ TiO_2 is another strategy to improve light absorption and activity of the catalyst. A 4.6-fold increase was observed in photocatalytic degradation of nitrobenzene (NBZ).²²⁹ Zhang *et al.* prepared a ferrocene-containing silicotungstate catalyst *via* a co-precipitation method for the photocatalytic oxidation of 4-chlorophenol (4-CP). It was suggested that the synergism between ferrocene and silicotungstate leads to the charge-transition from ferrocene to the POM unit, which ultimately contributes to the oxidation of the organic pollutant through a Fenton-like mechanism.²³⁰ In another study, $[\text{Cs}_3\text{PMo}^{\text{VI}}_{12}\text{O}_{40}]$ was used as a modifier of the

semiconductor Bi_2O_3 . The experimental results indicated that the $[\text{Cs}_3\text{PMo}^{\text{VI}}_{12}\text{O}_{40}]$ generated on the surface of the semiconductor creates a P–N heterojunction photocatalyst with visible-light activity in the degradation of phenol. The best photocatalytic performance was observed when 2.5 % (mol) of $[\text{Cs}_3\text{PMo}^{\text{VI}}_{12}\text{O}_{40}]$ was added to the semiconductor. Also, trapping experiments showed that the major active species involved in the degradation process are superoxide and hydroxyl radicals.²³¹ Heterogenization of POMs with graphene aerogels (GA) has also shown promise in the adsorptive removal of a series of organic compounds from water.²³² A more comprehensive analysis of the studies from the past 5 years is provided in Table S2 in Supporting Information.

2.4 Summary of water treatment technologies by polyoxometalates

Although the literature review shows promising evidence on how POM-based materials have attracted considerable attention for water treatment, like any emerging technology, they also have their own set of challenges and limitations. As tabulated in Table S2, POM-based materials have often been utilized as photocatalysts with high removal efficiencies. A key negative result that is rarely reported, but likely exists, is the structural instability of POM-based photocatalysts under realistic water matrices (containing chloride, carbonate, or natural organic matter). Such components can significantly suppress the photocatalytic activity or even partially decompose the structure, yet these effects are often not disclosed. Acknowledging this limitation is important for assessing the practical applicability of POM materials. For their broad implementation, they must also maintain the cost of processed water as low as possible. In this regard, substantial costs associated with synthesizing POMs and their composites remain as a significant challenge. In terms of the technology itself, other economically beneficial methods such as adsorption and ion exchange should also be considered, as they tend to provide more affordable solutions for water purification.

3 Removal of emerging health pollutants

Some of the most prominent classes of emerging health pollutants (EPs) are pharmaceuticals (antibiotics, antifungals, antidepressants, synthetic hormones)^{12,13,18,27,28,233} plant protection products (pesticides, biocides)^{31,234}, and microplastics.^{234,236,237} Excessive use of antibiotics and cosmetic products, *e.g.*, disinfectants and cleaning products, has led to the development of bacterial resistance through DNA mutations of bacterial cells, which have resulted in the adaptation and resistance of bacteria to these products.^{24,25,238} In addition, bacterial resistance also occurs through the horizontal gene transfer mechanism from resistant bacteria to non-resistant bacteria through transformation, transduction, or conjugation.²⁵ Moreover, water bodies containing EPs play an essential role in this horizontal gene transfer mechanism by facilitating the horizontal gene transfer from pathogenic to non-

pathogenic microorganisms. In addition to contributing to the development of antibiotic resistance, pollutants such as UV filters from sunscreens have been shown to harm marine life significantly. These compounds accumulate in aquatic environments and negatively affect organisms, including phytoplankton, corals, microalgae, and sea urchins, by disrupting their physiology and ecosystem functions.^{24,239}

A study, conducted over two consecutive years (2015 and 2016), on the final effluents from wastewater treatment plants in Europe, revealed high average concentrations of antibiotics in wastewater, especially in countries such as Portugal, Spain, and Ireland. The study identified that the most commonly found antibiotics, ciprofloxacin, azithromycin, and cephalexin, have a potentially significant impact on aquatic systems and the development of antibiotic resistance.^{24,240}

Ciprofloxacin, a fluoroquinolone antibiotic, and erythromycin have also been detected in effluents and surface waters in other studies²⁴, and are included, along with the macrolides azithromycin and clarithromycin, as well as the penicillin-type antibiotic amoxicillin, in the surface water Watch List under the European Water Framework Directive.^{17,240,241} More recently, this report has been updated to include other pharmaceutical products such as the antibacterials sulfamethoxazole and trimethoprim, the antifungal clotrimazole, fluconazole, and miconazole, the antidepressant venlafaxine, and the synthetic hormone norethisterone (Figure 10).^{240,241} In addition to the aforementioned pharmaceuticals, such as proton pump inhibitors (PPIs), lansoprazole and omeprazole,^{242,243} have been proposed as potential Watch List candidates due to their recently discovered possible mutagenic and toxic effects on aquatic organisms.^{17,25,240}

Figure 10. Emergent pharmaceuticals pollutants included in the updated 4th water watch list under the European Water Framework Directive: the antibacterial sulfamethoxazole and trimethoprim; the anti-fungal clotrimazole, fluconazole and miconazole; the antidepressant venlafaxine and the synthetic hormone norethisterone.¹⁷

Herein, we focus on the POMs' ability to degrade priority pharmaceuticals, mainly antibiotics, pesticides, microplastics,

and dyes, to identify POMs with higher removal efficiency and kinetics, thus facilitating the development of more environmentally friendly POM materials.^{244,245}

3.1 Removal of pharmaceutical pollutants

Every day, humans release pharmaceutical products into the environment in different forms and under different circumstances. This behavior of humanity has a major impact on health and economy and has a profound effect on our lives. It is therefore of great importance to conduct environmental protection in an effective and inexpensive manner to combat emerging health pollutants. Some of the most prominent classes of emerging pharmaceutical pollutants are the antimicrobial pharmaceuticals (antibiotics, antifungals) and other pharmaceuticals (antidepressants, synthetic hormones). It has been described that contamination of the environment with these pharmaceutical products can lead to bacterial resistance, which is an emerging and growing phenomenon worldwide in the 21st century.^{10,20,22,24,246} Nonconventional low-cost adsorbents for pharmaceutical removal from wastewater, pollutant removal mechanisms, and detection using nanodevices and polymer-based adsorbents, as well as using fungal treatments, were recently summarized.^{12,13,18} POMs have also been used for the detection of several pharmaceuticals, such as drugs of abuse²⁴⁷ and triclosan (TCS)²⁴⁸, as well for the selective extraction of antidepressants in undiluted urine.²⁴⁹ TCS, a diphenyl ether with antibacterial properties, is used as a disinfectant in antiseptic creams, toothpaste, hand soaps, deodorants, and even in plastics.^{21,22} In Europe, TCS is one of the most frequently detected contaminants in wastewater. However, studies from the United States have reported that its concentration in wastewater can be up to five times higher.²² TCS has already been detected in surface waters in several regions of the world, including in fish tissues. In fact, the methylated form of TCS (M-TCS) is bioaccumulative in tissues, due to its lipophilic properties and stability. Moreover, it has been described that contamination of the environment with TCS can lead to bacterial resistance to four antibiotics: chloramphenicol, tetracycline, ciprofloxacin, and colistin. This resistance poses potential risks to human health as well as aquaculture.^{21,22}

Of the seventeen pharmaceutical pollutants mentioned above, only one study has referred to the removal of ciprofloxacin by POMs. He *et al.* immobilized three Keggin-type POMs [$\text{H}_3\text{PMo}^{\text{VI}}_{12}\text{O}_{40}$] $\cdot n\text{H}_2\text{O}$, [$\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}$] $\cdot n\text{H}_2\text{O}$, and [$\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}$] $\cdot n\text{H}_2\text{O}$ onto nitrogen-deficient carbon nitride nanosheets (*g*- C_3N_4) and successfully utilized all three POM-based composites (Figure 11.A) for the removal of ciprofloxacin within only five minutes under visible light irradiation with 93.1 %, 97.4 % and 95.6 % efficiency, respectively.²⁵⁰ This type of POM-based hybrid material was further explored on *g*- $\text{C}_3\text{N}_4/\text{PW}_{12}/\text{TiO}_2$ composites ($\text{PW}_{12} = [\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}]$) (Figure 11.A-B)^{250,251}, which showed remarkable and stable photocatalytic performance under visible light irradiation, not only for the removal of TC but also for bisphenol A and Cr(VI).²⁵¹ Their removal properties and stability without any observed

structural changes in the photocatalyst were attributed to the enhanced adsorption under visible light irradiation, a high specific surface area, effective separation, and photoinduced charge transfer *via* g-C₃N₄ and PW₁₂.²⁵¹

A) Nitrogen-deficient g-C₃N₄/POMs porous nanosheets (where x denotes N-deficiency) with P-N heterojunctions capable of photocatalytic degradation of drugs; Recreated from Ref. 250 with permission from The Royal Society of Chemistry. B) Fabrication of g-C₃N₄/PW₁₂/TiO₂ composite with enhanced photocatalytic performance under visible light; Reproduced from Ref. 251 with permission from Elsevier, Copyright 2021.

Moreover, Cheng *et al.*²⁵² have utilized the isopolyoxotungstate, decatungstate [W^{VI}₁₀O₃₂]⁴⁻ (Figure 2.D) as a photocatalyst for the oxidation of sulfasalazine (SZZ)²⁵³, an antibiotic commonly found in wastewater, and its human metabolite sulfapyridine (SPD). After 120 min in the presence of H₂O₂ and under UV irradiation, the metabolite SPD was more efficiently removed (75 %) by decatungstate than was the SZZ antibiotic (25 %). The proposed photocatalytic mechanism (Figure 12), which involves the generation and utilization of hydroxyl radicals (•OH) in the photocatalytic degradation of sulfasalazine²⁵², has attracted increasing attention over the past decades. This mechanism has been extensively studied in the ongoing research and development of novel pollution removal technologies.^{254,255} Therefore, a similar strategy has been employed for the photodegradation of antibiotics such as nitrofurazone, tetracyclines and berberine under UV or visible light irradiation. This process utilizes H₂O₂ and the photoactive POM-based composite [H₃PW^{VI}₁₂O₄₀]@β-EDA-CD, as shown in Figure 13.A.²⁵⁶

Li *et al.* prepared a POM-based photocatalyst, $\text{PW}_{12}\text{@MFM-300}(\text{In})$ (Figure 13.B), by using an environmentally friendly solvent-free method for the encapsulation of the POM $[\text{H}_3\text{PW}_{12}\text{O}_{40}]$ into the metal-organic framework MFM-300(In). The $\text{PW}_{12}\text{@MFM-300}(\text{In})$ composite displayed its activity for room temperature visible-light-driven catalytic degradation of the pharmaceutically active compound SMT with a 98 % removal efficiency within 2 h.²⁵⁷

3.2 Removal of pesticides, microbes and microplastic

POM-based catalysts have been used for decades in pesticide degradation. The decatungstate $[\text{W}^{\text{VI}}_{10}\text{O}_{32}]^{4-}$, mentioned in the context of the removal of pharmaceutical pollutants (Section 3.1), also showed photocatalytic activity in the degradation of two common pesticides, 2-(1-naphthyl)acetamide (NAD) and 2-mercaptobenzothiazole (MBT). In the study of da Silva *et al.*, it was shown that $[\text{W}^{\text{VI}}_{10}\text{O}_{32}]^{4-}$ could promote UV-light-driven degradation of NAD with an efficiency of 89 % within 8 h.²⁵⁸ Additionally, Allaoui *et al.* described the photodegradation of the pesticide MBT using $\text{Na}_4\text{W}^{\text{VI}}_{10}\text{O}_{32}$ as a catalyst with an efficiency of 90% within 8 h.²⁵⁹ It has been proposed that the photodegradation of MBT occurs *via* e^- transfer and H-atom abstraction processes with $\text{W}^{\text{VI}}_{10}\text{O}_{32}^{4-*}$ excited species. The main products of such photodegradation when using decatungstate as a catalyst are monohydroxylated products, sulfoxide derivatives, and dimers of MBT. The whole process was shown to be O_2 dependent because photodegradation was restricted by $\text{W}^{\text{VI}}_{10}\text{O}_{32}^{5-}$ reoxidation.²⁵⁹ The Keggin-type POM $[\text{PW}_{12}\text{O}_{40}]^{3-}$ showed activity for the complete photocatalytic degradation of the pesticide lindane to CO_2 , H_2O , and Cl^- in an aqueous solution.²⁶⁰ Photocatalysis of lindane by $[\text{PW}_{12}\text{O}_{40}]^{3-}$ follows the same principle as that of TiO_2 catalysis, *i.e.* processes involving both oxidation and reduction pathways such as chlorination, dechlorination, hydroxylation, hydrogenation, dehydrogenation, which lead to the C-C bond cleavage and complete mineralization to the final products.²⁶⁰ Recently, a POM-IL²⁶¹ has also been used for the extraction of triazole pesticides (*e.g.*, penconazole, hexaconazole, diniconazole, tebuconazole, triticonazole, and difenconazole) from aqueous samples.²⁶² In that article, the prepared POM-IL nanomaterial ($[\text{3}-(1\text{-methylimidazolium-3-yl})\text{propane-1-sulfonate}]_3\text{PW}_{12}\text{O}_{40}$) was utilized as a coating for a new solid-phase microextraction (SPME) device that was then successfully applied for the extraction of the six triazole pesticides from real aqueous samples. The longevity experiments (at least 50 extractions) of POM-IL coated SPME devices compared with commercially available PDMS-coated SPME devices (PDMS = polydimethylsiloxane) showed that the newly prepared device offers higher extraction efficiency and better longevity.²⁶² Moreover, the type of POM-IL material (Figure 6), already described in Section 2.2, was shown to efficiently remove previously mentioned inorganic and organic contaminants from wastewater, as well as various microbial pollutants, *E. coli* and *B. subtilis*.⁶³ Recent developments in these organic/inorganic hybrid materials, POM-based ionic liquid crystals and POM-ILs,

and their applications, mainly in pollutants degradation, including microplastics, have been reviewed.²⁶³

Microplastics (MPs) are among the newly emergent health pollutants of worldwide concern, and their impact on human health and the environment is not yet completely understood.²⁶⁴ The first reported example of magnetic polyoxometalate-based ionic liquid phases (magPOM-SILPs) for the removal of MPs was designed by anchoring a POM-IL composite ($\text{POM} = [\alpha\text{-SiW}^{\text{VI}}_{11}\text{O}_{39}]^{8-}$ (Figure 2.F); $\text{IL} = (n\text{-C}_7\text{H}_{15})_4\text{N}^+$) to an Si-enclosed Fe_2O_3 supermagnetic core, $\text{Fe}_2\text{O}_3\text{@SiO}_2$ (Figure 14). The magPOM-SILPs composite showed remarkable effectiveness (90%) for removing microplastic by binding MPs particles via the formation of hydrophobic interactions with the MPs surface and then removing MPs pollutants from water samples by magnetic recovery (Figure 14).²⁶³

Cobalt-based POMs, $\text{Na}_{10}[\text{Co}_4(\text{H}_2\text{O})_2(\text{V}^{\text{V}}\text{W}^{\text{VI}}_9\text{O}_{34})_2]\cdot 34\text{H}_2\text{O}$ were also examined for dye degradation. MB and RhB dyes were chosen as the subject dyes for the degradation test because of their carcinogenic properties and wide use in the textile industry. A 10 mg/L dosage of this POM removed 87.8 % of MB in 30 min. The time required for the complete decomposition of RhB was almost twice as long as that of MB. In this study, in addition to the excellent dye catalytic activity, these CoV-POMs also showed anticancer activities.²⁶⁵ However, POMs anticancer, antibacterial studies, and other biomedical studies are described elsewhere.^{85,266,267,268} Another recent study, described the synthesis of two Keggin-type polyoxometalates ammonium phosphomolybdate $(\text{NH}_4)_3\text{PMo}^{\text{VI}}_{12}\text{O}_{40}$ (PMo) and ammonium phosphotungstate $(\text{NH}_4)_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}$ (PW) that were used as adsorbents for the removal of various antibiotics and heavy metals from water systems. The adsorption efficiency of PMo for dyes and heavy metals was higher than that of PW for various antibiotics such as tetracycline. It was suggested that the more negative surface charges induced by Mo atoms with more electronegativity and higher specific surface area contributed to the superior adsorption efficiency of PMo for dyes and heavy metals.²⁶⁹

Figure 14. Magnetic polyoxometalate-supported ionic liquid (magPOM-SILPs) for heavy metals, organic dyes, microbes and microplastics water removal.²⁶³

Table 1 summarizes the recent examples of POMs applications in removal of EPs covered in Section 3.

3.3. Summary of POM-based technologies in removal of emerging health pollutants

Section 3 highlights emerging pollutants in the 21st century environment, such as drugs, pesticides, and microplastics, and emphasizes their dangers and consequences for human health. Several examples illustrate the use of pure POMs, nanoparticles, composites, or MOFs for removing organic and

inorganic pollutants. The processes involving POMs in pollutant degradation are also discussed, many of which employ photocatalysis by UV and/or visible irradiation, in addition to adsorption or magnetic removal. In short, the different types of POMs mentioned in this section reveal their essential role in removing emerging pollutants from the environment, proving to be efficient and selective.

Table 1. Examples of recent polyoxometalates studies in pollutants degradation: antibiotics (A), dyes (D), plastics (P), industrial chemicals (IC) and pesticides (Pest).

4 Polyoxometalates in air pollution

Various POMs alone and in combination with other compounds^{117,278}, such as MOFs, CNTs and mesoporous silica supports, have shown promising results in the removal of air pollutants, such as refractory sulfur compounds²⁷⁹ from fossil fuels (Section 4.1), toxic gases such as hydrogen sulfide¹¹⁶ (Section 4.2.1), nitrogen oxides and sulfur dioxide²⁸⁰ (Section 4.2.2) and carcinogenic volatile organic compounds (VOCs; Section 4.3) present in indoor and outdoor air.^{281,282}

Among POM archetypes, Keggin-type structures dominate air purification applications due to their high catalytic activity, particularly in the oxidative desulfurization of refractory sulfur compounds from fossil fuels under mild conditions⁶¹ (~85 % of the reported literature; **Table S1**). Anderson-Evans POMs also contribute effectively to the desulfurization of fossil fuels by showing promising desulfurization performance through alkyl peroxide formation mechanisms with extended catalyst lifetimes.^{283,284} Wells-Dawson-type POMs, especially when doped with lanthanide ions, exhibit enhanced regeneration and stability, making them effective for toxic gas removal (Section 4.2; **Table 2**), such as H₂S, NO_x, and SO₂. Their tunable redox states and structural differences tailor their catalytic behavior, with rare-earth-doped Wells-Dawson POMs¹¹⁶ showing superior H₂S oxidation and the photocatalytic activity of Keggin/g-C₃N₄ composites enabling efficient VOC removal under visible light.^{285,286} These reported examples of using different POM structures highlight the unique functions and advantages that structural diversity in POM chemistry provides for air pollutant remediation.^{116,282,283,248,285}

4.1 Removal of refractory sulfur compounds from fossil fuels

The governments worldwide have introduced stricter regulations and restrictions on the amount of sulfur in fuels to ultra-low levels (< 10 ppm).⁵³ Therefore, the main goal of industry and science is to find a way to make the fuel desulfurization method efficient, inexpensive, clean, and safe.^{52,53} Currently, the established industrial standard for fossil fuel desulfurization is hydrodesulfurization (HDS). The HDS method has proven itself to be very effective in removing thiols, inorganic sulfides, and disulfides. However, due to new regulations requiring ultra-low sulfur fuels⁵³, HDS is insufficiently effective for removing the more difficult-to-remove refractory sulfur compounds. Moreover, HDS is a very expensive method and operates under harsh reaction conditions of 300–400 °C and 30–100 bar H₂ pressure. In contrast, POM-based oxidative desulfurization (ODS) operates under mild conditions (rt–100 °C, atmospheric pressure, H₂O₂/O₂ (**Table S1**)). POMs provide competitive advantages for the needed ultra-low sulfur fuels (< 10 ppm)⁵³ through their reversible multi-electron redox capability, oxygen-rich surfaces, and high catalytic stability. This eliminates high-pressure H₂ handling and reduces energy demands for heating and compression.^{52,61} ODS-based systems achieve 84–98 % sulfur conversion from 3.5 wt % to < 0.5 wt % with 55.57 % energy efficiency, demonstrating superior energy utilization for refractory sulfur compounds like DBTs.²⁸⁷ Electrochemical

regeneration (H₂O₂/O₂) further enhances POM recyclability (in most reported literature: > 95 % recovery, and 10+ cycles, **Table S1**). These data show that the ODS system is more energy cost-efficient for deep desulfurization than HDS.^{287,288}

He *et al.* reported a series of Keggin-type K_x[PMo^{VI}₁₂O₄₀] (K_xPMo, x = 1, 2, 3, 4) polyoxometalate salts prepared by hydrothermal synthesis using commercial F127 templates (Pluronic F127). The prepared K_xPMo salts (**Figure 15.A**) were mesoporous with a high surface area (> 40 m² g⁻¹) and could be successfully utilized for complete ODS of model oil in 1 h. By comparing the catalytic activity of the prepared POM salts, K₄PMo showed the highest activity in the ODS process with a DBT removal rate of 99.5 % within 60 minutes (**Table S1** in Supporting Information, *k* = 0.076 min⁻¹). A reaction mechanism of DBT oxidation by the K₄PMo/H₂O₂ catalytic system has been proposed (**Figure 15.B**).²⁸⁹ In addition, the K₄PMo catalyst also showed activity for the removal of other refractory sulfur compounds, DMDBT and BT, with removal efficiencies of 99.0 % and 60.3 %, respectively. The authors concluded that the ODS activity of K_xPMo catalysts has a linear correlation with their electrochemically active surface area (ECSA). The higher activity of the K₄PMo catalyst can therefore be attributed to its largest ECSA value, which shows that K₄PMo exposes the largest number of anions [PMo^{VI}₁₂O₄₀]³⁻ among all prepared catalysts. XRD structural analysis confirmed the good structural stability and successful recovery of the K₄PMo catalyst that was used.²⁸⁹

Figure 15. A) Illustration of one-pot hydrothermal synthesis of mesoporous K₄PMo material. The resulting K₄PMo material was highly crystalline with uniform and spherical morphology. It is denoted as K_xPMo, where x denotes the amount of HPMo added to the initial mixture. **B)** A schematic representation of the DBT oxidation mechanism in the presence of H₂O₂ catalysed by K₄PMo. DBT preferentially resides in the biphasic system's oil phase (n-octane), whereas the H₂O₂ oxidant and K₄PMo catalyst primarily reside in the extractant phase (methanol). Therefore, the first step is to extract into the extractant phase to react with H₂O₂ in the presence of K₄PMo.²⁸⁹

Besides commonly utilized Keggin-type POMs, other archetypes, especially Anderson-Evans and Wells-Dawson, have also been used in the ODS process. Eseva *et al.* prepared a series of Anderson-type polyoxometalates (**Figure 16**),

ARTICLE

Journal Name

$(\text{NR}_4)_3[\text{X}^{\text{III}}\text{Mo}^{\text{VI}}_6\text{O}_{24}\text{H}_6]$ ($\text{X}^{\text{III}} = \text{Cr}, \text{Fe}, \text{Co}$; $\text{R} = \text{H}$ or alkyl), and tested their catalytic properties in the ODS process of model fuel. The Co(III)-based Anderson type POM exhibited the highest catalytic activity in the desulfurization of model diesel with a 100 % conversion rate of DBT within 60 minutes with a molar ratio of $n(\text{S}):n(\text{cat.}) = 50:1$ (Table S1 in Supporting Information). By prolonging the reaction time to 120 min, 100 % conversion was also achieved for BT. However, for 3-methylbenzene, only 59 % conversion was achieved in 4 h.²⁸³ A reaction mechanism for DBT oxidation by the Co(III)-POM has been proposed (Figure 16). The crucial oxidation step in the catalytic system is based on the oxidation of a solvent (decalin), with the formation of an alkyl peroxide as the active species. Alkyl peroxide formation occurs by the reaction with an O_2 molecule from the air in the presence of a Co(III)-POM to form alkyl peroxides and the subsequent formation of the polyoxometalate's metal-dioxo species, as the source of active oxygen in the further oxidation of DBT. The quaternary ammonium cation in the $(\text{NR}_4)_3[\text{X}^{\text{III}}\text{Mo}^{\text{VI}}_6\text{O}_{24}\text{H}_6]$ catalyst structure allows the catalyst to adsorb the substrate molecules (DBT) and coordinate with the sulfur atom, after which the coordinated DBT is oxidized to a sulfone, thus simultaneously reducing $(\text{NR}_4)_3[\text{Co}^{\text{III}}\text{Mo}^{\text{VI}}_6\text{O}_{24}\text{H}_6]$ POM. The reduced form of $(\text{NR}_4)_3[\text{Co}^{\text{III}}\text{Mo}^{\text{VI}}_6\text{O}_{24}\text{H}_6]$ POM is re-oxidized with a new peroxide molecule, and a new catalytic cycle is started.²⁸³

Figure 16. A schematic representation of DBT oxidation mechanism catalyzed by Anderson-type polyoxometalates $(\text{NR}_4)_3[\text{X}^{\text{III}}\text{Mo}^{\text{VI}}_6\text{O}_{24}\text{H}_6]$ ($\text{X} = \text{Cr}, \text{Fe}, \text{Co}$; $\text{R} = \text{H}$ or alkyl) in the presence of O_2 from air.²⁸³

Hybrid POM-based materials have also been researched and have shown promising results as catalysts in ODS processes. Chi *et al.* reported the preparation of a new biomimetic catalytic system consisting of an Anderson-type POM $([\text{Na}_3\text{H}_6\text{Cr}^{\text{III}}\text{Mo}^{\text{VI}}_6\text{O}_{24}])$ and deep eutectic solvents (DESs) and its successful application as a catalyst for the removal of sulfur compounds from both model and commercial diesel.²⁸⁴ Six different DESs (PEG/PAS, PEG/SSA, PEG/SA, PEG/DHBA, PEG/PXA and PEG/DL-MA) were combined with CrMo_6 (Figure 17), and their activity was tested. Only the addition of PEG/SSA, DES, containing an $-\text{SO}_3\text{H}$ group, resulted in 100% sulfur removal, while utilizing other DESs resulted in no higher than 30 % sulfur removal.²⁸⁴ The desulfurization process followed the extraction-oxidation mechanism in which the POM and the DES acted as the electron transfer mediators and were both crucial for the process (Figure 17).²⁸⁴

Figure 17. Schematic representation of the reaction mechanism for the oxidation desulfurization of DBT catalysed by coupling CrMo_6 polyoxometalate with DESs under mild conditions ($T = 60^\circ\text{C}$).²⁸⁴

Ye *et al.* designed a new porous POM-based hybrid material by encapsulating a Keggin-type polyoxometalate $[\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}]$ (PW) in the metal-organic framework UiO-66(Zr) and employed it as a catalyst in the ODS reaction of BT, DBT, and DMBT at room temperature, with 98.2 % DBT removal efficiency.²⁹⁰ A proposed reaction mechanism includes the extraction of DBT molecules from the model oil into the acetonitrile phase by the POM catalyst and H_2O_2 . After extraction, DBT and H_2O_2 can be adsorbed into the catalyst pores, leading to the formation of $\bullet\text{OH}$ radicals via electron transfer from Zr- OH_2 active centers in UiO-66 (Zr). Another H_2O_2 molecule can react with a W(VI) metal ion in the $[\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}]$ POM to form the W(VI)-peroxo species that lead to the formation of $\text{O}_2^{\bullet-}$ radicals. Both $\text{O}_2^{\bullet-}$ and $\bullet\text{OH}$ radicals can oxidize DBT to DBTO₂. The existence of two types of active centers in the catalyst, W(VI) in $[\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}]$ and Zr- OH_2 in UiO-66 (Zr), which forms two different active species, is probably responsible for the high efficiency of the catalyst in the ODS process.²⁹⁰

For the desulfurization of fossil fuels, Gao *et al.* prepared a series of Wells-Dawson-type POMs $[\text{H}_{6+n}\text{P}_2\text{Mo}^{\text{VI}}_{18-n}\text{V}_n\text{O}_{62-n}\text{H}_2\text{O}]$ ($n = 1-5$; Mo_{17}V_1 , Mo_{16}V_2 , Mo_{15}V_3 , Mo_{14}V_4 , and Mo_{13}V_5), immobilized them on CNT carriers, and thereby prepared two different types of catalysts, CNT@PDDA@POM and POM@CNT.²⁹¹ All prepared POM-based materials have shown to be catalytically active in the ODS process. CNT@PDDA@ Mo_{16}V_2 showed the highest catalytic activity with 99.4 % desulfurization efficiency. The better efficiency of this type of catalyst was due to a different POM position in CNT@PDDA@POM (on the surface of CNT@PDDA) compared to POM@CNT (deep in the CNTs' channel). Moreover, it was observed that the number of Mo centers replaced with V centers affects the efficiency, with a 16:2 ratio being the optimal Mo:V ratio for obtaining a high desulfurization activity of both catalysts. By combining CNT carriers with high mechanical properties, high thermal stability, and a high specific surface area, Gao *et al.* overcame disadvantages such as a low specific surface area and the difficulty of reclamation for pure POMs.²⁹¹ More literature-known POM-based catalysts and their

efficiency in the removal of refractory compounds from fossil fuels are summarized in **Table S1** in the Supporting Information.

4.2 Removal of toxic gases - H₂S, NO_x and SO₂

4.2.1 Hydrogen sulfide (H₂S) in air pollution. Hydrogen sulfide is naturally present in crude petroleum, natural gas, volcanic gases, and geothermal sources. It is also a common by-product of many human activities, such as wastewater treatment²⁹², fossil fuel combustion⁵⁴, sewage treatment facilities⁵⁵, paper factories⁵⁶, food processing factories, and agriculture.⁵⁷ Hydrogen sulfide is an odorous toxic gas with a corrosive nature and an adverse effect on human health and directly affects industrial production by reducing industrial catalysts' efficiency and causing equipment failure. It can also easily oxidize and form SO₂ gas (**Eq. 1**), one of the leading causes of acid rain:⁵⁸

Furthermore, hydrogen sulfide readily reacts with metals, such as copper, and forms the corresponding sulfides (Cu₂S) on the surface of electrical devices, causing electrical failures. H₂S can also cause corrosion on surfaces, which can cause damage to buildings, for example, sewage plant facilities.²⁹³ In addition to SO₂ (Section 4.2.2), H₂S can react with different compounds present in the atmosphere and form many other toxic by-products, such as carbonyl sulfides (**Eq. 2**), carbon disulfides (**Eq. 3**), sulfurous acid (**Eq. 4**), and PMs, that have been linked to ozone layer depletion:²⁹⁴

Scientists and engineers have developed different methods for removing H₂S from the environment, such as metal oxide oxidation²⁹⁵, adsorption using different adsorbents (activated carbon or wet scrubbing)²⁹⁶, the Claus process²⁹⁷, biofiltration, oxidative desulfurization, and the LRSR process²⁹⁸. The latter two methods are recently the most commonly used methods with a very high desulfurization capacity and efficient production of elemental sulfur using various redox mediators (e.g., Fe(III)/Fe(II)).²⁹⁸ Such mediators have shown outstanding results, but they are still mostly chemically unstable and require low pH, which is unfavorable for H₂S removal processes.

POMs and different POM-based hybrid materials have shown high efficiency in H₂S removal due to their redox properties and structural stability. For the regeneration of these POM-based catalysts, a redox-mediated electrochemical regeneration method using oxidants such as H₂O₂ or O₂ has recently been shown to be effective.²⁸⁰

A purely inorganic POM was applied by Pei *et al.* who successfully synthesized a set of rare-earth Dawson-type polyoxometalates (K₁₇[Pr^{III}(P₂Mo^{VI}₁₇O₆₁)₂] (PrPMo), K₁₇[Gd^{III}(P₂Mo^{VI}₁₇O₆₁)₂] (GdPMo), K₁₇[Sm^{III}(P₂Mo^{VI}₁₇O₆₁)₂] (SmPMo) and K₁₇[Eu^{III}(P₂Mo^{VI}₁₇O₆₁)₂] (EuPMo)) and utilized them in the removal of H₂S. Due to the excellent redox

properties of Ln(III)-doped POMs, the influence of different Ln(III) species on H₂S removal was investigated. From the experimental results, the prepared compounds were ranked according to their efficiency for the removal of H₂S in the following order: PrPMo (90 %) > EuPMo (88 %) > SmPMo (87 %) > GdPMo (85 %). The PrPMo polyoxometalate showed the best desulfurization and regeneration properties with 90 % efficiency at 25 °C within 400 min. The XPS spectral analysis showed that H₂S is first oxidized to S by a redox reaction with PrPMo, in which Mo(VI) is simultaneously reduced to Mo(IV). During the electrochemical regeneration of PrPMo, S is further oxidized to SO₄²⁻ as the main desulfurization product, and Pr(IV) is reduced to Pr(III) during the regeneration process. The results of repeated XPS measurements confirmed the successful regeneration of PrPMo.¹¹⁶

Ma *et al.* described a new approach for an H₂S oxidation and sulfur recovery system using the hybrid POM-based hybrid materials, [C₄mim]₃PMo^{VI}₁₂O₄₀-ILs ([C₄mim]⁺ = 1-butyl-3-methylimidazolium cation), where they investigated the influence of several different [C₄mim]⁺-based ionic liquids (ILs), [C₄mim]Cl, [C₄mim]BF₄, [C₄mim]PF₆ and [C₄mim]NTf₂. Of all the POM-IL systems tested, the [C₄mim]₃PMo^{VI}₁₂O₄₀-[C₄mim]Cl system has shown to be the most effective for removing H₂S, with 100 % efficiency. The adsorption mechanism of H₂S desulfurization is explained by the theory of cavities and the strong interaction between H₂S and Cl⁻. Additionally, they confirmed that the POM-IL material could be successfully recovered more than six times without losing its efficiency.²⁹⁹

Figure 18. Crystal structure of POM-MOF ([{(CH₃)₄N}₄CuPW₁₁O₃₉H]) material. The [CuPW₁₁O₃₉]⁵⁻ polyhedra are orientationally disordered into the pores. It was concluded that the catalytic decomposition of H₂S was taking place inside the pores.³⁰⁰

Song *et al.* prepared a POM-based metal-organic framework [{(CH₃)₄N}₄CuPW^{VI}₁₁O₃₉H] (POM-MOF) hybrid material (**Figure 18**) by combining a Keggin-type polyoxometalate [CuPW^{VI}₁₁O₃₉]⁵⁻ and MOF-199.³⁰⁰ The POM-MOF/O₂ catalytic system effectively oxidizes H₂S to solid S₈ with up to 95 % H₂S removal efficiency. Additionally, it has been shown that the POM-MOF system can successfully oxidize mercaptans to disulfides. The POM-MOF catalyst can be successfully reused in the oxidation process after simple filtration, washing, and drying. The UV-VIS and FT-IR spectra showed that the [CuPW^{VI}₁₁O₃₉]⁵⁻ structure was preserved in the POM-MOF catalyst at pH 11 for at least 12 h. The POM-MOF hybrid material showed better stability and pH resistance than the [CuPW^{VI}₁₁O₃₉]⁵⁻ POM alone.³⁰⁰

A summary of literature-reported POMs and POM-based hybrid materials and their efficiencies in H₂S removal are given in **Table 2** at the end of Section 4.

4.2.2 Nitrogen oxides (NO_x) and sulfur dioxide SO₂ in air pollution. Interest in NO_x emissions and their regulation began after 1952 with the confirmation of their role in the formation of photochemical smog.³⁰¹ Several different nitrogen oxides are present in the atmosphere, e.g., N₂O, NO, NO₂, N₂O₃, N₂O₄, NO₃, and N₂O₅. However, NO_x mainly refers to NO and NO₂ oxides because nitrogen oxides are primarily released into the environment in these forms, and NO_x emissions contain 95 % NO and 5 % NO₂.³⁰² NO is considered less toxic than NO₂ and can cause eye irritation, but NO₂, even at low concentrations, can cause acute lung injury with pneumonitis³⁰³ and fulminant pulmonary edema.³⁰⁴ In urban areas where a higher concentration of NO₂ gas present, many respiratory and cardiovascular diseases and even increased mortality among the exposed population have been observed.^{303,305} Moreover, H₂S and NO_x gases are considered to be among the major air pollutants because they are thought to be responsible for various environmental issues, such as photochemical smog, acid rain³⁰⁶, tropospheric ozone³⁰⁷, ozone layer depletion, and even global warming, as a result of N₂O.^{308,309} NO_x gases are also associated with the greenhouse effect, and in the higher layers of the atmosphere, they can react with various compounds present there (O₃, VOCs, etc.), leading to ozone depletion. Most air pollution occurs and remains within the lowest layer of the atmosphere, the troposphere. NO_x gases can lead to the formation of tropospheric ozone after photochemical degradation to NO (**Eq. 5**):

With NO not absorbing radiation above 230 nm and thus not acting as an inhibitor in the lower atmosphere, the resulting atomic oxygen reacts with O₂ in the troposphere to form ozone (**Eq. 6**), leading to the tropospheric ozone formation.^{301,307} Great efforts have been made to develop methods for removing NO_x from the atmosphere in the last few decades.^{306,310,311} Adsorptive-desorption methods^{307,309} and Fenton-like reactions²⁸⁵, as examples of AOPs, have been extensively studied for the removal of NO_x and SO₂ gases. The Fenton-like oxidation process consists of oxidation and degradation of different pollutants in the presence of a catalyst and H₂O₂ as an oxidant activated by UV-light irradiation.^{280,311} In the oxidation process, the generated reactive •OH radicals (**Eq. 7**) oxidize a wide range of different substrates. Such radical-assisted oxidation processes have been shown to be particularly effective in removing organic dyes, phenols, antibiotics, and insecticides from wastewater and are a popular research topic for pollution removal applications.²¹²

Zhao *et al.*³¹² reported the synthesis of an iron-substituted Keggin-type polyoxometalate-based catalyst Fe^{III}AspPW from

ferric chloride (FeCl₃), aspartic acid (Asp), and phosphotungstic acid ([H₃PW^{VI}₁₂O₄₀]). The Fe^{III}AspPW was used to activate H₂O₂ to form active •OH species, which are crucial for the removal of NO from flue gas. The proposed catalytic mechanism consists of two redox cycles that occur on the surface of the Fe^{III}AspPW catalyst: the redox cycles of Fe^{III} ↔ Fe^{II} and POM ↔ POM[•]. In the Fenton-like process, first, in the redox cycle of Fe^{III} ↔ Fe^{II}, Fe³⁺ reacts with H₂O₂ to first form HOO• (**Eq. 8**) and then •OH (**Eq. 9**) active species:

In the POM ↔ POM[•] redox cycle, the POM component is firstly reduced to the POM[•] form in a reversible reaction, and then the reduced POM[•] form further reacts with H₂O₂ to form active •OH species (**Eq. 13**). In addition, to close the redox cycle, POM[•] is oxidized by O₂ or O₂[•]:

This catalytic system showed great activity for removing NO with 94.6 % efficiency.³¹² Moreover, Liu *et al.* showed that the Fe^{III}AspPW/H₂O₂ catalytic system could also be used to simultaneously remove SO₂ and NO from flue gas in a UV-Fenton-like process with efficiencies of the Fe^{III}AspPW catalyst of 100 % for SO₂ removal and 84.27 % for NO removal.³¹² Wang *et al.* presented a series of Ge(IV)-based Keggin-type polyoxometalates ([H₄GeW^{VI}₁₂O₄₀] (HGeW), [H₅GeW^{VI}₁₁V^{VO}₄₀] (HGeWV), [H₅GeMo^{VI}₁₁V^{VO}₄₀] (HGeMoV), [H₅GeW^{VI}₉Mo^{VI}₂V^{VO}₄₀] (HGeWMoV)) and utilized them in the removal of NO_x pollutants.³¹³ The adsorption-desorption experiments showed the following adsorption efficiencies for the removal of NO_x gases: HGeW (81.5 %) > HGeWV (74 %) > HGeWMoV (67 %) > HGeMoV (52 %). The Keggin-type polyoxometalate HGeW (**Figure 2.E**) showed the highest NO_x removal activity with 81.5 % removal and 68.3 % N₂ selectivity, of which 65% was from fractionated NO and 35 % NO₂ gas. Additionally, the H₂S removal efficiency of HGeW was compared with that of the parent Keggin [H₃PW^{VI}₁₂O₄₀] (HPW) polyoxometalate (54.1 % efficiency). The FT-IR studies revealed that NO_x is adsorbed on HGeW mainly in the form of NOH⁺ and NO• species, but on the HPW, only NOH⁺ is observed as the main form during adsorption. Moreover, TPD-MS experiments were carried out to investigate the further decomposition mechanism of NO_x over HGeW and HPW. The TPD-MS analysis showed that while the decomposition products (NO, N₂O, N₂, and O₂) appear in the same order for both HPW and HGeW, they appear at different temperatures, lower in the case of HPW. The NO species appeared at the lowest temperature for both NO_x decomposition experiments. It is believed that a significant part of the NO_x is physically adsorbed onto HPW and HGeW in the

form of NO at a lower temperature. Meanwhile, the later appearing N₂O could be a product of the disproportionation reaction of NO in which N₂ is formed because of the bonding effect of N-atom, which comes from N-O bond breakage. The difference in NO_x removal efficiency and N₂ selectivity between HPW and HGeW could be due to the HGeW's ability to intensively loosen the N-O bond, resulting in easier NO_x decomposition, and by better NO_x adsorption for HGeW in the form of both NO• and NOH⁺. It is believed that the presence of the Ge(IV) atom instead of P as the central atom plays a significant role in the processes described above.³¹³

4.3 Volatile organic compounds in air pollution (VOCs)

4.3.1 Removal of volatile organic compounds - refractory BETX compounds (benzene, ethylbenzene, toluene, and xylenes).

VOCs are a group of liquid organic compounds that can easily evaporate at room temperature. In addition to their volatility, this group of compounds has variable lipophilicity, small molecular size, and are uncharged, resulting in inhalation as the primary route of human exposure.³¹⁴ VOCs are classified according to molecular structure and functional groups and include aliphatic hydrocarbons, aromatic hydrocarbons, alcohols, ethers, esters, aldehydes, etc. Due to their properties and wide application in different areas of everyday life, they are common indoor and outdoor air pollutants.^{314,285} As outdoor pollutants, they result from the development of industry and urbanization, which involves the increased use of fossil fuels in transport, industrial production, and wastewater treatment plants. As indoor air pollutants, VOCs are found in tobacco smoke, various air fresheners and perfumes, paints and coatings, cleaning products, etc., and can be harmful to human health at excessive concentrations.^{285,286,314} Especially, the group of so-called refractory BETX compounds, which stands for benzene, ethylbenzene, toluene, and xylenes, is problematic due to their high toxicity and confirmed carcinogenic nature.^{285,314} Besides being confirmed carcinogens, depending on the concentration and length of exposure, various consequences of VOCs exposure have been reported: eye and respiratory tract irritation, headache, dizziness, allergic skin reaction, fatigue, memory impairment, loss of consciousness, and even death.^{286,315,316}

Various methods³¹⁴ have been studied in search of an efficient and affordable method for removing volatile organic compounds (VOCs) from the air, such as condensation, adsorption^{317,318}, and (photo)catalytic oxidation.³¹⁴ Photocatalytic oxidation (PCO) is a promising method for removing VOCs from the air, and so far, TiO₂-based photocatalytic oxidation³¹⁸ has mainly been investigated. Due to the tendency to develop a sunlight/visible-light-driven method, TiO₂ has been shown to be a non-ideal photocatalyst due to its poor solar energy utilization.³²⁰ Therefore, there is a need to design new materials that could be successfully applied as photocatalysts for VOCs' photocatalytic oxidation.^{315,321}

Meng *et al.* have shown that photoactive PW₁₂/g-C₃N₄ optical films (Figure 19.B) can be obtained by combining the Keggin-

Figure 19. A) Reaction mechanism of photocatalytic oxidation of VOCs catalysed by PW₁₂/g-C₃N₄ films. B) Schematic representation of the preparation of PW₁₂/g-C₃N₄ catalyst and its framework structure.²⁸⁶

type POM, [H₃PW^{VI}₁₂O₄₀], with polymeric graphitic carbon nitride (g-C₃N₄) and then successfully utilized them as photocatalysts for the efficient removal of benzene, toluene, and *m*-xylene. The PW₁₂/g-C₃N₄ optical films showed excellent removal efficiencies for benzene (90.3 %), toluene (100 %) and *m*-xylene (97.5 %). They also demonstrated excellent stability and reusability for up to 30 cycles without signs of activity loss. The results of DMPO spin-trapping ESR measurements indicated that the PW₁₂/g-C₃N₄ films follow a simulated sunlight-driven direct Z-scheme-dictated charge carrier transformation mechanism that accelerates interfacial charge carrier separation and the formation of O₂^{•-} and HO• radicals that are involved in VOCs oxidation. In the suggested mechanism (Figure 19.A), charge separation and formation of e_{CB}⁻-h_{VB}⁺ pair occur (photocurrent), resulting in the formation of O₂^{•-} and HO• active species that directly participate in the complete mineralization of VOCs to CO₂ and H₂O (Figure 19.A).²⁸⁶ Also, Gamelas *et al.* presented a series of new cellulose/silica hybrid composites functionalized with different Keggin-type POMs ([PV^V₂Mo^{VI}₁₀O₄₀]⁵⁻, [PV^VMo^{VI}₁₁O₄₀]⁴⁻, [PMo^{VI}₁₂O₄₀]³⁻ and [PW^{VI}₁₂O₄₀]³⁻) and investigated their potential application in the catalytic oxidation of VOCs present in urban air.²⁸¹ The new cellulose/silica hybrid materials were composed of approximately 56 wt % of polysaccharides, ca. 37 wt % of propylamine-modified silica, 2 wt % of POM, and 5 wt % of hydration water. Catalytic activity experiments were performed by pumping polluted air through Teflon tubes filled with the catalysts and then analyzing the treated air by GC-chromatography.

The catalytic activity of the new POM-based hybrid material for VOCs oxidation was visible as a change in the color of the material from yellow to green, indicating the occurrence of $V(V) \rightarrow V(IV)$ reduction in the POM. The GC-chromatography of a real air sample treated with the new hybrid material indicated complete oxidation of most C_5 - C_{11} volatile organic compounds. The successful recovery of the used catalyst was achieved by passing purified air through the Teflon tubes filled with used catalyst, which was noticeable by the color change of the material from green to yellow.²⁸¹

POMs have also proven as suitable adsorbents for adsorption techniques to remove VOCs from the air. Ma *et al.* reported a newly synthesized POM/MOF hybrid material, $K_2[Cu_{12}(BTC)_8 \cdot 12H_2O][HPW^{VI}_{12}O_{40}] \cdot 28H_2O$ or NENU-28 and its possible application as an adsorbent for the adsorption of VOCs, including short-chain alcohols (MeOH and EtOH), cyclohexane, benzene, and toluene.³²² The adsorption capacity of NENU-28 for methanol, ethanol, 1-propanol, 2-propanol, cyclohexane, benzene and toluene was tested in VOCs adsorption experiments. The adsorption amount of MeOH for NENU-28 is 6.70 mmol g^{-1} which corresponds to the adsorption of 37.52 molecules of MeOH per catalyst formula unit. Comparison with the initial MOF ($Cu_3(BTC)_2$), which can adsorb 5.14 mmol g^{-1} methanol (14.36 MeOH molecules per formula unit), shows that POM-functionalized MOFs bring a significant improvement in the adsorption capacity for MeOH. The NENU-28 hybrid material also showed an increase in the amount of adsorbed EtOH (4.78 mmol g^{-1} or 26.77 molecules of EtOH per formula unit) compared to $Cu_3(BTC)_2$ (3.54 mmol g^{-1} or 9.89 molecules of EtOH per formula unit). Although the mechanistic details are not fully understood yet, the results indicate that the presence of the Keggin-type POM [$HPW_{12}O_{40}$] in the NENU-28 has a favorable effect on the adsorption properties of the POM-MOF material.³²²

4.3.2 Removal of aldehydes. Aldehydes, especially formaldehyde and acetaldehyde, are the most common VOCs present in the air as indoor air pollutants.³²³ The primary sources of these air pollutants come from building materials, varnishes, and paints, flooring, and furniture materials. Formaldehyde and acetaldehyde are classified as Group 1 carcinogens and are therefore proven harmful to human health.^{323,324} Several approaches have been developed to reduce their concentration. They can be divided into passive (e.g., better ventilation, using formaldehyde-free materials) and active (e.g., removal techniques – adsorption and catalytic oxidation) approaches.^{323,324} In this section, the focus will be on the development of different active approaches for the removal of aldehydes.

$[H_4SiW^{VI}_{12}O_{40}]$ and $[K_8SiW^{VI}_{11}O_{39}]$ (0 % efficiency). Kholdeeva *et al.* developed a new Ce-containing polyoxometalate $NaH_3[SiW^{VI}_{11}Ce^{IV}O_{39}]$ (Ce-POM; **Figure 20**)²⁷⁸ and its dimer in the solid-state, and tested their promising efficiency in the removal of formaldehyde (CH_2O) under mild conditions (20–40 °C). Although the reaction mechanism itself is complex and involves CH_2O autooxidation, the Haber-Weiss radical-chain process,³²⁵ and product formation inhibition, the reaction stoichiometry itself satisfies the equation in **Figure 20**. The efficiency of an

unoptimized oxidation process of CH_2O in the presence of Ce-POM/ O_2 (efficiency 25 %) was compared to the oxidation of CH_2O in the presence of $Ce(SO_4)_2$ (efficiency 9 %) and in the presence of two POMs without Ce(IV) metal atom. The results of these efficiency comparisons suggested that the activity of the Ce-POM catalyst could be attributed to the synergistic action of the POM and Ce(IV). By optimizing the reaction conditions (adding a small amount of H_2O_2), the conversion efficiency of CH_2O increased from 25 % to 85 % with a yield of 66 % HCOOH in the presence of $NaH_3[SiW^{VI}_{11}Ce^{IV}O_{39}]$.²⁷⁸

Figure 20. Aerobic oxidation of formaldehyde to formic acid catalysed by Ce-containing Keggin-type POM ($NaH_3[SiW^{VI}_{11}Ce^{IV}O_{39}]$) under mild conditions (air, $T = 25^\circ C$).²⁷⁸

Gamelas *et al.* successfully immobilized the α -isomer of the polyoxometalate $[SiW^{VI}_9O_{37}Ru^{III}_3(H_2O)_3Cl_3]^{7-}$ (Ru-POM) onto a CSH support, obtaining a heterogeneous catalyst Ru-POM-CSH that was active in formaldehyde oxidation.³²⁶ Oxidation of CH_2O was performed at room temperature by flushing an air/formaldehyde gas mixture through a Teflon tube filled with Ru-POM-CSH catalyst or only the CSH carrier without POM. Initially, the CH_2O degradation results for the first two cycles did not differ significantly between CSH and Ru-POM-CSH. This lack of degradation increase could be explained by chemisorption and the reaction between the amino groups of the CSH carrier and CH_2O :

After the second cycle, the efficiency of CSH in the removal of CH_2O dropped sharply. By the 4th cycle, it was 0 %, which indicates the simple saturation of the CSH carrier. When Ru-POM-CSH was used as a catalyst, efficiency decreased more slowly, with about an 8 % decrease between cycles after the 5th cycle. No catalyst saturation was observed, which can be attributed to the oxidation of CH_2O catalyzed by Ru-POM. After passing purified air through a Teflon tube containing Ru-POM-CSH material, unlike CSH alone, the material was successfully regenerated. Product analysis revealed that CO_2 and H_2O were the main reaction products formed by catalytic oxidation of CH_2O in the presence of Ru-POM-CSH. These results indicate that the reaction undergoes a predominantly non-radical mechanism because the final product would be formic acid and carbon monoxide in the case of a radical mechanism.³²⁶

The following mechanism of a CH_2O oxidation reaction in the presence of Ru-POM-CSH was proposed:

The initial step probably involves oxidation of the substrate (CH_2O) by a catalyst through ligand replacement, binding of O_2 to the partially reduced catalyst (Eq. 9), and its activation and further reaction with $\bullet\text{CHO}$:

The oxidation reaction of CH_2O with Ru-POM-CSH can be summarized as follows:³²⁵

Kholdeeva *et al.* also synthesized tetra-*n*-butylammonium (TBA) salts of Co-substituted Keggin-type polyoxometalates [TBA₄HPW^{VI}₁₁CoO₃₉] (I) and [TBA₅PW^{VI}₁₁CoO₃₉] (II) (Co-POM) and immobilized them onto both NH_2^- and NH_3^+ modified mesoporous silica surfaces.²⁸²

The catalytic activity of the solid Co-POM materials (I) and (II) was tested for the oxidation of isobutyraldehyde (IBA) and compared with the activity of the homogeneous Co-POM salts (I) and (II). The results showed that the IBA conversion rate in MeCN under mild conditions (1 atm of air, $T = 20-40^\circ\text{C}$) without a catalyst was 28 %. In the presence of only the NH_2^- -modified mesoporous silica support, the IBA conversion rate was only 6 %, indicating that the NH_2^- silica support is an inhibitor of the IBA oxidation. When one of the solid Co-POM catalysts, [TBA₄HPW^{VI}₁₁CoO₃₉] (I) or the non-protonated [TBA₅PW^{VI}₁₁CoO₃₉] (II), (immobilized on NH_2^- or NH_3^+ -silica support) was added to the reaction mixture, the IBA oxidation to IBAC continued at room temperature. The protonated salt [TBA₄HPW^{VI}₁₁CoO₃₉] (I) had a higher redox potential and better catalytic activity for IBA oxidation than the non-protonated salt

(II). The catalytic activity of the immobilized Co-POM (I) and the homogeneous salt (I) exhibited similar catalytic performance (92 % IBA conversion) for the first two cycles. However, after the third cycle, the immobilized Co-POM (I) catalyst lost up to 15 % of its activity due to Co-POM leaching, showing that the homogeneous Co-POM (I) salt had better long-term stability.²⁸² All literature-known polyoxometalates and their applications in removing aldehydes are summarized in Table 2.

4.4 Summary of POM-based technologies in air purification

Various POMs alone and combined with MOFs, CNTs, and mesoporous silica supports show promising results for removing air pollutants including refractory sulfur compounds from fossil fuels (Section 4.1), toxic gases like H_2S (Section 4.2.1), NO_x/SO_2 (Section 4.2.2), and carcinogenic VOCs (Section 4.3) in indoor/outdoor air. Keggin-type POM structures dominate oxidative desulfurization of fossil fuels under mild conditions (~85 % of literature; Table S1), outperforming traditional HDS processes and avoiding high pressures/temperatures while meeting ultra-low sulfur regulations. Anderson-Evans POMs enable efficient desulfurization through alkyl peroxide mechanisms with extended lifetimes, while lanthanide-doped Wells-Dawson POMs exhibit superior H_2S oxidation and stability for NO_x/SO_2 removal (Table 2).

POM-based hybrid materials further enhance performance, such as K_4PMo mesoporous salts for rapid DBT removal (Table S1), $\text{PW}_{12}/\text{g-C}_3\text{N}_4$ films mineralizing BETX VOCs under visible light via Z-scheme mechanism, and POM-MOFs like NENU-28 boosting VOC adsorption (Section 4.3). Ce- and Ru-containing Keggin POMs catalyze aldehyde oxidation to $\text{CO}_2/\text{H}_2\text{O}$ at room temperature, with Ru-POM-CSH showing sustained activity over cycles without saturation (Table 2). Structural diversity tailors redox properties and active oxygen species ($\bullet\text{OH}$, $\text{O}_2^{\bullet-}$), addressing key air pollutants effectively.

Table 2. List of polyoxometalates and POM-based materials utilized in air purification. All POMs are ordered chronologically from the most recent to the oldest published paper.

REMOVAL OF H_2S

5 Polyoxometalates in sensor applications

Immobilization of POMs on the different supporting surfaces facilitates their electrochemical properties for sensor applications.³⁵⁰ Numerous methods, such as chemical adsorption^{351,352}, electrodeposition^{353,354}, encapsulation³⁵⁵, the Langmuir-Blodgett process^{356,357}, and layer-by-layer deposition^{358,359}, have been used to deposit POMs on electrodes to form monolayer or multilayer structures.³⁵² As can be seen in **Figure 21**, POM-based sensors are used as the analytical unit, in which the POM is immobilized onto a solid substrate utilized as a transducer. If the POM has been successfully immobilized onto the transducer while preserving its structural integrity, the POM part of the sensor should be able to recognize and catalyze the analyte *via* an induced chemical reaction followed by the transformation of the chemical reaction energy into an electrical signal. The electrical signal is later amplified and converted by signal processing equipment into a display.³⁴⁹ The POM-based sensors, like other sensors, show all main characteristics such as sensitivity, selectivity, linear range, response time, detection limit, and stability.³⁶⁰ The most critical properties of most POM-based sensors are selectivity and response rate, and often, they are not addressed by authors. For sensors to have high selectivity, the sensor should have a heightened response to a substrate but an inadequate response to interferences. Recently, it has been shown that these issues could be solved by combining the POMs with organic moieties or CNTs with the addition of noble metal NPs. Generally, the POM-based sensors showed good selectivity and low response time while being stable and active at neutral pH.^{360,361}

POM-based sensors operate through a synergistic mechanism that involves redox-driven signal transduction, coordination-induced structural alterations, and catalytic amplification processes. This enables the highly sensitive detection of various chemical and biological analytes. The multi-electron redox functionality of POM clusters allows them to undergo reversible changes in oxidation state upon interaction with target species, resulting in measurable outputs that can be electrochemical, optical, or conductometric. In the realm of electrochemical sensing, POMs facilitate rapid electron transfer at the electrode-analyte interface, a process that can be enhanced through their incorporation into conductive matrices or nanostructured supports, thereby optimizing charge-transfer kinetics and reducing detection limits.³⁶² Optical sensors utilize intervalence charge-transfer transitions or ligand-to-metal charge-transfer phenomena that occur when analytes interact with or reduce the POM framework, resulting in observable shifts in absorbance or luminescence.³⁶³ Furthermore, the catalytic sensing mechanisms exploit the inherent oxidative or reductive catalytic properties of POMs, where reactions initiated by the analyte generate amplified signals under controlled conditions such as specific pH levels, ionic strength adjustments, or the presence of co-substrates.³⁶⁴ The overall performance of these sensors is heavily influenced by various experimental factors, including the speciation of POMs, electrode modification strategies, solvent polarity, and the

stability range of the POM in the working environment. Consequently, methodological optimization becomes vital for achieving selectivity, reproducibility, and reliability in practical applications.³⁶⁵

Figure 21. Schematic representation of POM-based electrochemical sensors.³⁴⁹

5.1 POM-based sensors in the detection of water pollution

The POM-based sensors have already explored various analyte classes dispersed in either the gas or liquid phase. The electrocatalytic reduction of nitrate, iodate, bromate, nitrite, and hydrogen peroxide by POMs immobilized on a substrate was carried out for sensing applications. Starting with stable Keggin and Dawson type POMs ($[\text{H}_3\text{PMo}^{\text{VI}}_{12}\text{O}_{40}]$, $[\text{H}_6\text{P}_2\text{Mo}^{\text{VI}}_{18}\text{O}_{62} \cdot n\text{H}_2\text{O}]$, $[\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}]$, $[\text{P}_2\text{W}^{\text{VI}}_{18}\text{O}_{62}]^{6-}$, and $\alpha\text{-}[\text{H}_4\text{SiMo}^{\text{VI}}_{12}\text{O}_{40}]$) are extensively explored as electrochemical sensors.^{361,366–369} Though the sensors showed prominent sensitivity and wide linear range, they operated at a low pH ($\text{pH} < 2$) to stabilize the POM architecture.³⁷⁰ In 2012, Ma *et al.*³⁷¹ synthesized a layer-by-layer composite film using palladium nanoparticles and a Dawson-type POM ($[\text{K}_7\text{P}_2\text{W}^{\text{VI}}_{17}\text{O}_{61}(\text{FeOH}_2) \cdot 8\text{H}_2\text{O}]$, $(\text{P}_2\text{W}^{\text{VI}}_{17}\text{Fe})$) to determine the electrolytic behavior towards the oxidation of hydrazine sulfate ($\text{N}_2\text{H}_4\text{SO}_4$) and reduction of hydrogen peroxide. The H_2O_2 exhibits sensitivity, detection limit, and linear concentration in the range of $66.7 \mu\text{A mM}^{-1}$, $1 \mu\text{M}$ ($\text{S/N} = 3$), $1.5 \mu\text{M}$ to 3.9 mM , respectively. Likewise, $\text{N}_2\text{H}_4\text{SO}_4$ displays the same parameter in the range of $0.2 \mu\text{A mM}^{-1}$, $1.5 \mu\text{M}$ ($\text{S/N} = 3$), $2 \mu\text{M}$ to 3.4 mM , respectively, with sensing response time around 4 s .³⁷¹ Furthermore, Zhu *et al.*³⁷² synthesized four Preyssler-type POM-based organic-inorganic crystals to effectively detect non-enzymatic H_2O_2 . The compounds exhibit the lowest detection limit of 0.13 mM with a high sensitivity of $4.35 \mu\text{A mM}^{-1}$ and a response time of 1 s .³⁷² Ag-doped MoO_3 immobilized on the graphene-like carbon nitride (C_3N_4) was first prepared and employed as an electrochemical sensor by Zhao *et al.*³⁷³ to detect H_2O_2 . Herein, $[\text{Ag}_6\text{Mo}^{\text{VI}}_{12}\text{O}_{42}]/\text{Ag-MOF}$ precursor was used to synthesize the nanoporous structure resulting in a linear detection range of $0.25 \mu\text{M}$ – 0.43 mM towards H_2O_2 owing to its efficient electrocatalytic property.³⁷³ Additionally, isopolymolybdate-based compounds are explored as photoelectric sensors for detecting inorganic ions (e.g., Cr(VI) , Hg^{2+} , NO_2^-).³⁷⁴ Additionally, complex POM structures (e.g., pyrazole derivative Keggin ions,³⁷⁵ 3D coordination polymers doped with Keggin POM³⁷⁶ or hourglass-type POM

crystals³⁷⁷ have been explored as the active electrode for the acute and faster sensing of bromate, nitrate, and heavy, metal ions.

5.2 POM-based sensors in the detection of air pollution

Krutovtsev *et al.* first addressed POM-based gas sensors by employing various Wells-Dawson type POMs doped with polyaniline to detect ammonia gas.³⁷⁸ POM-doped conducting polymer film is ideal for gas sensing as POMs react with the gas, and conducting polymer substrate converts that into an electrical signal. The recognition of other hazardous gases, such as NO_x, CO, and the vapors of organic solvents, can also be determined because the proton-conducting POMs enhance the material's selectivity and sensitivity.^{379,380} Ammam *et al.*³⁸¹ recently reported a sensitive and selective NO_x gas sensor using the [K₆P₂Mo^{VI}₁₈O₆₂·H₂O] POM and polypyrrole (PPy), exhibiting extended linearities (up to 5500 ppm NO_x). Although all so far mentioned POM-modified electrodes shows catalytic properties and can recognize the analyte, not all can be employed as sensors. In order to achieve a high-performance sensor, the modified electrode should fulfill the conditions of molecular recognition between POMs and specific analytes.³⁸¹ A high-performance gas sensor was developed by Wang *et al.*³⁸² by using heteropolytungstate (HPT) doped SnO₂ nanorods [HPT abbreviation as (C₄H₁₀ON)₂₃[HN(CH₂CH₂OH)₃]₁₀H₂[Fe^{III}(CN)₆(α₂-P₂W^{VI}₁₇O₆₁Co^{II})₄·27H₂O]·SnO₂/HPT composite film, which demonstrated higher photoconductivity than pristine SnO₂ and revealed improved gas sensing for the methylbenzene and formaldehyde at room temperature (25 °C). Electron-hole recombination in the composite was retarded due to the photo-induced transfer of an electron from SnO₂ to HPT. An n-type semiconductor material BiVO₄ loaded with different POMs, was exploited as a photo-anode for photoelectrochemical gas sensing capability for NO₂.³⁸² Among different Keggin type POMs ([Na₇PW^{VI}₁₁O₃₉], [H₃PW^{VI}₁₂O₄₀], [H₃PMo^{VI}₁₂O₄₀], [Na₁₀SiW^{VI}₉O₃₄], [H₃PW^{VI}₁₂O₄₀]) displayed the highest photocurrent response intensity. In addition, BiVO₄/[H₃PMo^{VI}₁₂O₄₀] demonstrates an enhanced response of 32.8 % toward 50 ppm of NO₂.³⁸³ In similarity with the previous discussion, herein, the electron-hole recombination was slowed down as the POM facilitates charge separation and photogenerated electron transfer to the semiconductor. Shi *et al.*³⁸⁴ made an interface modification on the grain boundary by integrating TiO₂, and Ti^{IV} substituted POMs (K₅[PW^{VI}₁₁Ti^{IV}O₄₀] and K₅[PW^{VI}₁₀Ti^{IV}O₄₀]). The resultant nanocomposite exhibited improved photoconductivity and elevated gas sensing properties towards acetone gas.³⁸⁴ Tian *et al.*³⁸⁵ investigated the effect of [H₃PW^{VI}₁₂O₄₀] doped In₂O₃ compound for gas sensing at room temperature toward formaldehyde. The doping of the POM successfully suppressed the recombination of photo-induced carriers in the system resulting in a 35 % enhancement in photoconductivity alongside a 26 % gas sensing response compared with pristine In₂O₃.³⁸⁵ Similarly, Wang *et al.*³⁸⁶ also incorporated [PW^{VI}₁₂O₄₀]³⁻ with Cu₂ZnSnS₄ for high-performance NO₂ gas sensors. The composite exhibited 88.83 % enhanced gas sensing properties compared with pristine

Cu₂ZnSnS₄ due to the restriction of electron-hole recombination and effective charge transfer through the POM.³⁸⁶ Furthermore, Sun *et al.*³⁸⁷ developed dye-sensitized TiO₂-PW₁₂ using a simple, economical sol-gel method followed by a screen-printing technique for faster NO₂ gas sensing at room temperature under visible light irradiation. The heterostructure enabled faster separation and transportation of the photogenerated carriers as the POM acted as the electron acceptors. The effective increase in sensitivity (233.1–1 ppm) over a wide range of NO₂ concentration (50 ppb–5 ppm) for POM decorated dye/TiO₂ film occurred due to the expansion of the narrow bandgap of the POM doped dye under visible light without loss in thermal energy.³⁸⁷ An inorganic-organic hybrid film was fabricated by Kida *et al.* for selective H₂ (50–500 ppm) and NH₃ (10–100 ppm) sensing using yttrium-stabilized zirconia with Mo^{VI}₇O₂₄⁶⁻/hexylamine hybrid film. Calcination of the POM alkylamine hybrid film resulted in porous MoO₃ particles, making them an effective precursor for synthesizing nanosized metal oxide.³⁸⁸ POM-based supramolecular chemosensors were developed for the acute gas sensing of toxic gases. Wei *et al.* demonstrated a CO₂ sensor using Na₉DyW^{VI}₁₀O₃₆ and block copolymer poly (ethylene oxide-*b*-N, N-dimethyl aminoethyl methacrylate).³⁸⁹ Likewise, Guo *et al.* developed POM-based supramolecular chemosensors for H₂S detection (detection limit 1.25 μM) with dual signals (*via* absorption spectra and fluorescence).³⁹⁰ In the field, rapid detection of acutely corrosive and toxic gases like H₂S at room temperature is important. Bezdek *et al.* developed enhanced chemiresistive gas sensors to detect H₂S using highly oxidized Pt-doped POM with single-walled CNT. They have also demonstrated ppb level detection with high stability and a wide range of selectivity.³⁹¹ Furthermore, Liu *et al.*³⁹² immobilized POMs on a polyelectrolyte matrix and then used them for the sensitive detection of NO. The ability to electrocatalyze the reduction of NO resulted in a wide range of selectivity (1 nM to 10 μM).³⁹² Triethylamine gas sensors developed by Cai *et al.*³⁹³ exhibited ultra-sensitive selectivity and stability over repeated use. One-dimensional heterostructure nanofibers of ZnO and ZnWO₄ were synthesized *via* POM (varying the molar ratio of H₃PW^{VI}₁₂O₄₀) assisted electrospinning methods. The highly porous structure of the nanofibers and the synergistic effect between the ZnO and ZnWO₄ resulted in an enhanced relative response of 108.5 for 50 ppm triethylamine. The barrier-control electron transfer at the interface was attributed to remarkable selectivity with a low detection level of 150 ppb.³⁹³ The recent advances led Tian *et al.*³⁹⁴ to fabricate POM-semiconductor heterojunctions via a one-step coaxial electrospinning technique for the effective sensing of ethanol gas. One-dimensional tandem heterojunctions SnO₂/POM/WO₃ significantly increased the sensing characteristics compared with the SnO₂/WO₃ nanofibers. The sensitivity was optimized to 100 ppm of ethanol. The construction of the interface allowed the POM to act as the electron acceptor, promoting faster carrier separation and exhibiting enhanced sensing behavior.³⁹⁴ Next, a bottom-up POM-assisted *in-situ* growth of 1D nanofilament architecture was achieved by electrospinning, followed by the thermal oxidation method for the detection of

acetone. A broad range of concentration, *i.e.*, 50 ppb–50 ppm, was detected with enhanced selectivity and sensitivity owing to the charge transfer to the interface of the ZnO–ZnMoO₄ nanofilament.³⁹⁵ A unique nanostructure was developed by Ren *et al.*³⁹⁶ using Pt-draped Si-doped WO₃ nanowires interwoven into a three-dimensional mesoporous superstructure for low-temperature ethanol gas sensing (with a detection limit of 0.5 ppm).³⁹⁶ Selective and ultrasensitive dual detection (Raman and photochromic) of ethylenediamine gas was demonstrated by Zhang *et al.* using POM/viologen hybrid crystal. It exhibits a very low detection limit of 0.1 ppb via Raman signal output.³⁹⁷

5.3 POM-based sensors in the detection of emerging health pollutants

Very recently, Wang *et al.*³⁹⁸ synthesized isostructural Anderson-type POM-based compounds and fabricated photoelectric sensors to detect inorganic ions. Three different transition metal ions (M^{II} = Co^{II}, Cd^{II}, Zn^{II}) were incorporated for the preparation of the [M₂^{II}(H₃bdpm)₂TeMo^{VI}₆O₂₄·6H₂O] (H₃bdpm = 1-1'-bis(3,5-dimethyl-1H-pyrazolatemethane) compounds which contain a 2D supramolecular layer and 1D chain structures. All prepared [M₂^{II}(H₃bdpm)₂TeMo^{VI}₆O₂₄·6H₂O] compounds have been successfully utilized as fluorescence sensors toward Cr₂O₇²⁻ at different concentrations. Furthermore, the compounds with Co^{II} and Cd^{II} also exhibited electrochemical sensing behavior for detecting NO₂⁻ (Cd-containing compound possesses a response time of 2.16 s at a detection limit of 5.11 × 10⁻⁵ M alongside a sensitivity of 43.10 μA mM⁻¹).³⁹⁸

POM and Zn-based complexes derived from pyrazole were reported by Tian *et al.* for photocatalysis and electrochemical

sensors to detect hydrogen peroxide, bromate, and nitrite by tuning pH.³⁹⁹ Likewise, Zhang *et al.* tuned the N and O coordination donors in morpholine and piperazine derivatives to derive various POM-based compounds for photocatalysis, electrochemical, and fluorescent sensor applications (towards Hg²⁺).⁴⁰⁰ Furthermore, researchers explored POM-modified MOFs for various sensing applications, *e.g.*, photocatalytic, electrochemical (towards the detection of inorganic ions, H₂O₂, Cr(VI), bromate, *etc.*).^{401–405}

All literature known polyoxometalates and their applications in sensing are summarized in **Table 3**.

5.4. Summary of POM-based sensors

POM-based sensors for water pollution, air pollution, and emerging health pollutants are discussed thoroughly. In aqueous sensing, Keggin, Dawson, Preyssler, and isopolymolybdate POMs exhibit strong electrocatalytic activity toward species such as hydrogen peroxide, nitrate, bromate, nitrite, and heavy metal ions, often achieving low detection limits and quick response times. For gas sensing, POM–polymer, POM–metal oxide, and POM–semiconductor heterostructures enable the sensitive and selective detection of gases, including NO₂, NH₃, H₂S, formaldehyde, acetone, ethanol, and volatile amines, mainly by promoting charge separation and reducing electron–hole recombination. Lastly, emerging health-related pollutants are addressed through advanced POM-based supramolecular systems, MOFs, and hybrid complexes that offer electrochemical, photoelectrochemical, and fluorescent sensing modes. Overall, the manuscript highlights the versatility of POMs as functional building blocks for high-performance, multifunctional sensors that operate under mild and environmentally friendly conditions.

Table 3. Summarization of the reported POM-based sensors.

6 Polyoxometalate based battery and supercapacitors

POMs emerge as an exceptional electrode component for supercapacitors (SCs) or batteries due to their high proton mobility and extraordinary redox chemistry.^{406–408} POM's variable redox activities and outstanding electron/proton transport capacities apply POM-based composite materials in electrochemical fields. As a powerful electron reservoir in the multi-electron reduction process, POM enables high proton conductivity even in the composite. This interesting behavior has led to various applications of POM-based composites such as green catalysis, sensors, and electrochemical energy storage devices (batteries and SCs). However, POMs are pH-sensitive; therefore, a well-known strategy of coordination chemistry has been used to enhance the mechanical and electrochemical properties of the electrode material for better performance.^{407–411}

6.1 POM-based battery electrodes

6.1.1 POM as the electrode for lithium-ion batteries (LiBs).

Transition metal oxides are used as the cathode/anode material for LiBs as they are oxidized to their highest oxidation state when the Li has been released.⁴¹² The first reported POMs for LiB are focused on polyoxomolybdates.⁴¹³ Further improvements of the electrode material have been made by modifying the structural and electronic states of POMs, altering the reversible faradaic reaction associated with them. Vanadium-based POMs are being explored as cathode materials for rechargeable batteries to achieve high energy and power density by multi-electron redox processes via fast transfer of Li ions. Chen *et al.*⁴¹⁴ reported Li₇[V^V₁₅O₃₆(CO₃)] as a cathode material with a specific capacity of 250 mA h g⁻¹ alongside energy and power densities of 1.5 kW h L⁻¹ and 55 kW L⁻¹, respectively. Additionally, Li₇[V^V₁₅O₃₆(CO₃)] exhibits a very high potential window (1.9 to 4.0 V) for reversible redox reactions. The theoretical calculation for the specific capacity for the oxometalate mentioned above at the same potential window (by considering *n* is 14, which is the next nearest integer no. of electrons) shows the specific capacity of 259 mA h g⁻¹, which is in corroboration with the experimental data.⁴¹⁴ Further, the vanadium-based K₇[NiV^V₁₃O₃₈] structure is explored by Ni *et al.*⁴¹⁵ The maximum discharge capacity of 218.2 mA h g⁻¹ was

recorded at a discharge current density of 17 mA g⁻¹ with 93.2 % coulombic efficiency.⁴¹⁵ Thus, the nano-sized polyoxovanadates can be utilized as cathode materials for LiBs for moderate capacity and rate capability.

Furthermore, POMs are combined with carbonaceous nanostructures for better cycle and rate performance. Ma *et al.*⁴¹⁶ synthesized covalent functional pyrene (Py) with [H₄SiW^{VI}₁₂O₄₀] (SiW₁₂) and attached it to the surface of SWCNTs *via* spontaneous adsorption. SWCNT/Py-SiW₁₁ exhibited an initial discharge capacity of 1569.8 mA h g⁻¹ at a current density of 0.5 mA cm⁻². However, the capacity decreased to 580 mA h g⁻¹ after 100 cycles at the same current density.⁴¹⁶ Graphene sheets are represented by single-layer two-dimensional sp²-bonded carbon atoms, having a high affinity towards POMs. Wang *et al.*⁴¹⁷ synthesized environmentally friendly nanomaterials by incorporating reduced graphene oxide (rGO) with Keggin type [H₄SiW^{VI}₁₂O₄₀] (SiW₁₂) clusters. rGO/SiW₁₂ exhibits a discharge capacity of 275 mA h g⁻¹ with an increased potential of 4 V at a current density of 50 mA g⁻¹. The nanocomposite can hold a capacity of 120 mA h g⁻¹ at 1.5 V operating potential even at a high current density of 2000 mA g⁻¹.⁴¹⁷ Besides carbonaceous nanostructures, POMs are often synthesized with silver nanoparticles due to their chemical structure, elevated surface area, and high electrical conductivity.^{418,419}

In recent years, the POM-based composite structure has been further modified by including MXenes, e.g., i) POM@PANI/Mo₂TiC₂TxMXene/CNTs delivers lithium storage capacity of 621 mA h g⁻¹ at 0.1 A g⁻¹ and promising cyclic stability (445 mA h g⁻¹ after 1000 periods at 1.0 A g⁻¹)³⁹⁰; and ii) PMo₁₂@PPy/Ti₃C₂T_x delivers high capacity of 764 mA h g⁻¹ at 0.1 Ag⁻¹ with long cycling stability of 2000 cycles at 3 A g⁻¹.⁴²⁰ Additionally, the hybridization of various POMs with different supports such as porphyrins⁴²⁰, CoS₂/MoS₂/functionalized rGO⁴²¹, and various MOFs^{422–425} results in enhanced lithium capacity and overall stability as an anode.

6.1.2 POM as the electrode for sodium-ion batteries. Besides LiBs, POM-based composites are applied as cathode/anode material for Na-ion batteries. Liu *et al.*⁴²⁶ prepared a robust composite by coating Na₂H₈[MnV^V₁₃O₃₈] (POM) clusters on the graphene nanoflakes. The discharge process of the composite demonstrates a two-phase reaction due to the presence of V(V)/V(IV) redox couple related to Na-ion insertion, and a high capacity of 202 mA h g⁻¹ is recorded at 1.5 V (at the end of the

ARTICLE

Journal Name

discharge). Furthermore, the composite can retain 81 % of its initial capacity over 100 cycles at 0.2 C with 95 % coulombic efficiency.⁴²⁶ Hartung *et al.*⁴²⁷ reported that the sodium salt of decavanadate, $\text{Na}_6[\text{V}_{10}\text{O}_{28}]$, acts as a high-performance cathode material for rechargeable Na-ion batteries. The potential discharge range observed from the CV graph is within the range of 0.01–3.0 V. The capacitive process associated with the $\text{Na}_6[\text{V}_{10}\text{O}_{28}]$ ion is completed by the insertion of the Na ion in the voids of $[\text{V}_{10}\text{O}_{28}]^{6-}$ cluster.⁴²⁷ Additionally, MOFs are proven to be effective supporting materials for POMs. Using a simple impregnation strategy, Cao *et al.*⁴²⁸ demonstrated that $\text{PMo}_{12}/\text{MIL-88B}/\text{GO}$ composite delivers an excellent specific capacity of 214.2 mA h g⁻¹ for 600 cycles at 2 A g⁻¹. Another example is a layer-by-layer arrangement of vanadium-based POM immobilized on Co-based MOF resulted in a capacity of 413 mA h g⁻¹ due to accommodating the larger Na⁺ ions efficiently.⁴²⁸

6.2 POM-based supercapacitor electrodes

Electrochemical capacitors or SCs, on the other hand, are promising energy storage devices that meet a significant performance gap between batteries and electrostatic capacitors. They supply high-power electric pulses over a short time scale, exhibiting a high dynamic of charge propagation with elevated charge and discharge rates.⁴²⁹ In the maximum reported SC, high capacitance and energy are achieved by incorporating a pseudocapacitive or faradaic type of active material with a double-layer capacitive component. Mostly, metal oxides and sulfides show promising results for SC electrodes as they generate a large number of charges at the electrode interface via multi-step reversible redox reactions.

6.2.1 Composite-type hybrid electrode. Early in 2005, Gómez-Romero *et al.*⁴⁰⁷ established the POM-based composite hybrid electrode for SC as they dispersed three different POMs, namely, $[\text{H}_3\text{PW}_{12}\text{O}_{40}]$, $[\text{H}_4\text{SiW}_{12}\text{O}_{40}]$, and $[\text{H}_3\text{PMo}_{12}\text{O}_{40}]$, in the conducting polymer PANI. The highest specific capacitance of 120 F g⁻¹ with cycle stability over 1000 cycles was observed for PANI/ $[\text{H}_3\text{PMo}_{12}\text{O}_{40}]$, which is higher than the other two POM ($[\text{H}_3\text{PW}_{12}\text{O}_{40}]$, $[\text{H}_4\text{SiW}_{12}\text{O}_{40}]$) composite, due to the higher proton conductivity of the $[\text{H}_3\text{PMo}_{12}\text{O}_{40}]$ in 1 M HClO_4 electrolyte.⁴⁰⁷ In the later years, the same group deposited $[\text{H}_3\text{PMo}_{12}\text{O}_{40}]$ on different conducting polymers (e.g., poly(3,4-ethylenedioxythiophene) (PEDOT)) with an external oxidizing agent (H_2O_2) for further electrochemical improvement (Figure 22).⁴⁰⁸ Later, the Freund's⁴³⁰ group used the same Keggin POM, $[\text{H}_3\text{PMo}_{12}\text{O}_{40}]$, incorporated into the porous PPy, exhibiting a specific capacitance of 210 F g⁻¹ in 0.5 M H_2SO_4 electrolyte in three-electrode configuration.⁴³⁰ Recently, Vannathan *et al.*⁴³¹ reported high-performance pseudocapacitors of vanadium substituted Keggin POMs and combined with a conducting polymer for enhancement of electrochemical activity.⁴³¹ Carbonaceous nanostructures (e.g., CNT, GO/rGO, AC) come into play as the supporting elements to the POMs as they provide better mechanical and electrochemical stability.⁴²⁹ To replace the conducting polymer as a supporting element for POM, inventors need a high electrical conducting substrate like

the former. CNTs exhibit higher electrical conductivity due to their hierarchical architecture among all the carbonaceous

Figure 22. Schematic illustration of steps involved in synthesizing polypyrrole nanotubes and polyoxometalates (POMs, PMo_{12} , or PW_{12}) hybrid material with the simple chemical method.⁴⁰⁸

nanostructures. At first, Cuentas-Gallegos *et al.*⁴³² prepared a single-wall CNT and POM composite using Cs substituted phosphomolybdate ($\text{Cs}[\text{PMo}_{12}\text{O}_{40}]^{3-}$). The composite material presented a specific capacitance of 285 F g⁻¹ and an energy density of 57 W h kg⁻¹.⁴³² Later Shunik *et al.*⁴³³ further developed this concept using multi-walled CNT instead of a single wall. Phosphomolybdic acid-modified multi-walled CNT revealed a specific capacitance of 40 F g⁻¹ at a discharged current of 7 mA.⁴³³ Furthermore, to achieve a higher surface area substrate without compromising electrical conductivity, the researchers employed AC as a supporting material because it possesses a larger surface area (up to 3000 m² g⁻¹) with different pore distribution (micro, meso, or macropores). Ruiz *et al.*⁴³⁴ prepared a hybrid electrode by integrating activated carbon with Keggin-type phosphomolybdate $[\text{H}_3\text{PMo}_{12}\text{O}_{40}]$ (PMo_{12}). The highest specific capacitance was generated due to the faradaic component, around 183 F g⁻¹ at 2 A g⁻¹ current density.⁴³⁴ In 2014, the same group used molybdenum-based POMs instead of phosphotungstate $[\text{H}_3\text{PW}_{12}\text{O}_{40}]$ for an electrochemical study and observed an enhancement of the capacitance to 254 F g⁻¹ in an operating potential of 1.6 V. Moreover, the composite can possess 98 % capacitance over 30000 cycles.⁴³⁵ Besides Keggin-type POMs, Mu *et al.*⁴³⁶ for the first time embedded a Dawson-type POM, $(\text{NH}_4)_6[\text{P}_2\text{Mo}_{18}\text{O}_{62}]$ on AC and achieved the highest capacitance of 308 F g⁻¹ at 2 A g⁻¹ current density due to the high proton conductivity and unique redox behavior of the faradaic component.⁴³⁶ Besides commercially available activated carbon, Lian *et al.* used biomass-derived pinecone activated carbon, in which POMs ($\text{PMo}_{12}\text{O}_{40}^{3-}$) contributed to a high specific capacitance of 361 F g⁻¹, showing the trend of proton-coupled electron transfer (Figure 23).⁴³⁷ Recently, Maity *et al.*⁴³⁸ developed vanadium-substituted Keggin structures ($\text{PMo}_{11}\text{VO}_{40}$ and $\text{PMo}_{10}\text{V}_2\text{O}_{40}$) impregnated into the surface of AC. The vanadium

concentration in the polyanion plays a vital role as it decides the morphology and microstructure of the nanocomposite.⁴³⁸

Figure 23. Synthesis schematic for porous pinecone biomass carbon and fabrication of pinecone – polyoxometalate hybrid material.⁴³⁷

Graphene or its oxide derivatives (GO and rGO) are used mainly as substrate components other than CNTs and AC because of their high surface area with sizeable electrical conductivity. Additionally, the presence of oxygen-containing functional groups in GO and rGO enables many active sites for the physisorption of a faradaic component. Gomez-Romero and his team did permutation and combined possible routes to achieve high-performance SC using POM and graphene offshoots.^{439,440} In this course, they have found a new route to synthesize the hybrid PMo_{12} -rGO nanoelectrode with a hydroquinone-doped hybrid gel hybrid electrolyte. The double hybridization enhances cell potential (1.6 V) and electrochemical properties by increasing the volumetric capacitance to 3.18 F cm^{-3} . Similarly, for the phosphotungstate composite (rGO-PW₁₂), the areal capacitance is calculated as 2.95 F cm^{-3} .^{439,440}

Instead of a single supporting medium for POMs, Qin *et al.*⁴⁴¹ (Figure 24) prepared a new type of composite by anchoring PMo_{12} to PPy/rGO by layer-by-layer deposition for high-performance micro-SC in solid gel electrolyte medium (PVA/H₂SO₄; PVA = polyvinyl alcohol). The resultant composite exhibited high energy and power densities of 4.8 mW h cc^{-1} and 645.1 mW cc^{-1} , respectively. Also, due to the presence of a solid electrolyte, it presents excellent mechanical flexibility (96 % capacitance retention at a highly bending angle of 180°).⁴⁴¹ Furthermore, surface modifications of graphene derivatives were made using various POM structures, demonstrating enhanced electrochemical performances.^{442–445} To achieve seamless ion transportation to the electrode/electrolyte interface Maity *et al.*⁴⁴⁶ designed and tailored a facile bottom-up approach in which vanadium-substituted Keggin POMs ($\text{PMo}_{11}\text{VO}_{40}$) were used to oxidize pyrrole monomer followed by the deposition on the GO surface. The resultant nanohybrid not only exhibits unique architecture but displays high-performance supercapacitive behavior.⁴⁴⁶ The designing and construction of polyoxometalates-based metal-organic frameworks composites further expands the search for promising high-performance electrode materials for SCs. A Dawson type⁴⁴⁷ the basket-shaped heteropoly blue⁴⁴⁸, Keggin type⁴⁴⁹, and Anderson type^{450,451} POMs hybridized in metal or covalent organic frameworks overcome the limitations of POMs, e.g.,

high solubility in common electrolytes and results in better stability over longer cycles with improved capacitance.

Figure 24. Scheme illustration of fabrication procedure of mPPy@rGO-POM nanosheets.⁴⁴¹

6.2.2 Asymmetric type hybrid electrode. Asymmetric type hybrid enhances electrochemical performances in two ways; for instance, incorporating two types of material in a single device enables different charge storage mechanisms simultaneously. Secondly, the cell voltage is tuneable (mainly can be enhanced) due to the presence of various active materials in electrodes. Chen *et al.*⁴⁵² studied the electrochemical properties of vanadium-based iso-polyanion, sodium decavanadate ($[\text{Na}_6\text{V}_{10}\text{O}_{28}]$) in 1 M LiClO_4 organic solution, exhibiting an excellent electrochemical behavior in a 3-electrode configuration. Furthermore, an asymmetric SC configuration was developed using activated carbon as the positive and $[\text{Na}_6\text{V}_{10}\text{O}_{28}]$ as the negative electrode, exhibiting a maximum specific capacitance of 269 F g^{-1} , with energy and power densities of 73 W h kg^{-1} and 312 W kg^{-1} , respectively, in a 2.8 V operating potential.⁴⁵² Hu *et al.*⁴⁵³ studied a composite type of electrode using regular PMo_{12} anchored on AC in a protic ionic liquid electrolyte. Later, the nanocomposite was assembled as an asymmetric SC device with commercially available AC. The asymmetric cell operates in an elevated potential window of 0–0.85 V, even at a high current density (10 A g^{-1}).⁴⁵³

Dubal *et al.*⁴⁵⁴ developed a high-performance symmetric SC based on $\text{PMo}^{\text{VI}}_{12}$ and $\text{PMo}^{\text{VI}}_{12}$ -rGO. They assembled an asymmetrical SC device using rGO- $\text{PMo}^{\text{VI}}_{12}$ and rGO-PW^{VI}₁₂ electrodes for higher energy density. The SC cell also operates at 1.6 V potential and elevated energy density of 39 Wh kg^{-1} at a power density of 658 W kg^{-1} .⁴⁵⁴ Maity *et al.*⁴⁵⁵ optimized the effective loading of POM ($\text{Ni}^{\text{IV}}\text{V}_{14}\text{O}_{40}$)⁷⁻ on the AC surface for the first time and employed the nanocomposite as the cathode in an asymmetric configuration with AC as the anode. The resultant device exhibited an enhanced specific energy of 90 W h kg^{-1} and specific power of 2400 W kg^{-1} . Moreover, the nanocomposite-based asymmetric configuration with pristine POM as the positive electrode showed supercapattery behavior.⁴⁵⁵

All literature-known POM-based batteries and supercapacitors are summarized in Table 4.

6.3. Summary of POM-based batteries and supercapacitors

The use of polyoxometalates (POMs) as advanced electrode materials for electrochemical energy storage highlights their

remarkable redox activity, high proton mobility, and fast electron/proton transport. These inherent qualities make POMs appealing for use in batteries and supercapacitors, although their sensitivity to pH and solubility issues necessitate structural modifications and hybridization via coordination chemistry to develop mechanically durable and electrochemically stable electrodes. In batteries, especially those based on vanadium- and molybdenum-based clusters, POMs serve as active materials in lithium- and sodium-ion batteries. Their multi-electron redox processes allow for moderate to high specific capacities and a wide range of operating potentials. Hybridizing POMs with conductive supports, such as carbon nanotubes, graphene, MXenes, metal nanoparticles, MOFs, and polymer matrices, significantly improves capacity retention, rate performance, and long-term cycling stability. These approaches

effectively overcome the limitations of pure POMs and facilitate efficient ion accommodation. In supercapacitors, POM-based composite and asymmetric electrodes bridge the performance gap with batteries by combining faradaic pseudocapacitance and electric double-layer storage. Key supports such as conducting polymers, carbon materials, graphene derivatives, and porous carbons enhance electrical conductivity, surface area, and mechanical strength. Advanced hybrid structures—including layer-by-layer assemblies, POM–graphene gels, MOF-supported POMs, and asymmetric devices—offer high specific capacitance, broader voltage ranges, excellent energy and power densities, and long cycle life. Overall, this manuscript presents POM-based composites as versatile, high-performance electrode platforms for future energy storage solutions.

Table 4. Summarization of the reported POM-based battery and supercapacitors.

POM-based Composite	POM Archetype	Type of Energy Storage	Significant Results	Ref.
$\text{Li}_7[\text{V}_{15}\text{O}_{36}(\text{CO}_3)]$	spherical isopolyvanadate	Li-ion Battery	specific capacity of 250 mA h g^{-1} alongside energy and power density of 1.5 kW h L^{-1} and 55 kW L^{-1} , respectively	392
SWCNT/Py-SiW ^{VI} ₁₁ ; SWCNT = single-walled carbon nanotubes	lacunary Keggin	Li-ion Battery	exhibits an initial discharge capacity of $1569.8 \text{ mA h g}^{-1}$ at a current density of 0.5 mA cm^{-2}	394
$\text{Na}_2\text{H}_8[\text{MnV}_{13}\text{O}_{38}]$ cluster on the graphene nanoflakes	trimeric polyoxovanadate	Na ion Battery	high capacity of 202 mA h g^{-1} is recorded at 1.5 V with 81% of its initial capacity retention over 100 cycles	396
PANI/H ₃ PMo ^{VI} ₁₂ O ₄₀ ; PANI = polyaniline	Keggin	composite type SC	highest specific capacitance of 120 F/g with cycle stability over 1000 cycles	385
$([\text{PV}^{\text{V}}\text{Mo}_{11}\text{O}_{40}]^{4-}, [\text{PV}^{\text{V}}_2\text{Mo}_{10}\text{O}_{40}]^{5-})$ with AC	Keggin	composite type SC	AC-VMo ₁₁ composite displayed an enhanced capacitance of 450 F g^{-1} with an improved energy density of 59.7 W h kg^{-1} alongside 99.99% capacitance retention of over 5000 cycles	407
PMo ^{VI} ₁₂ to PPY/rGO by layer-by-layer deposition; PPY = polypyrrole; rGO = reduced graphene oxide	Keggin	composite type SC	composite possesses high energy and power densities of 4.8 mW h/cc and 645.1 mW/cc , respectively	410
$[\text{MnV}_{14}\text{O}_{40}]^{6-}$ on the AC and GO; AC = activated carbon; GO = graphene oxide	Lindqvist	composite type SC	AC/MnV ₁₄ nanohybrid exhibits a specific capacitance of 547 F g^{-1} with specific energy and power of 76 W h kg^{-1} and 1600 W kg^{-1} , respectively, at 0.8 Ag^{-1} current density. GO/MnV ₁₄ shows a specific capacitance of 330 F g^{-1} with specific energy and power of 30 W h kg^{-1} and 1276 W kg^{-1} , respectively, at the same current density	414
PMo ^{VI} ₁₂ anchored on AC in a protic ionic liquid; AC = activated carbon	Keggin	asymmetric SC	asymmetric cell operates in a potential window of $0-0.85 \text{ V}$ at 10 A g^{-1} of current density	417
rGO-PMo ^{VI} ₁₂ and rGO-PW ^{VI} ₁₂ ; rGO = reduced graphene oxide	Keggin	asymmetric SC	the cell operates at 1.6 V potential and elevated energy density to 39 W h/kg with a power density of 658 W/kg	426
AC//AC-K ₂ H ₅ [NiV ^{IV} ₁₄ O ₄₀]; AC = activated carbon	Lindqvist	asymmetric SC	increased the potential window up to 1.5 V and enhanced the specific energy and power values (90.1 W h kg^{-1} and 2400 W kg^{-1} , respectively), with 98% coulombic efficiency	427

7 Conclusions and Outlook

It is almost impossible to overemphasize the applications of POMs in environmental remediation. By looking at the number of environmental studies mentioning POMs in the removal of various pollutants from water, soil or air, it seems that POMs are involved everywhere. This increasing number of environmental degradation studies (Figure 3) involving POMs could be mostly explained by the versatility of the structural chemistry of POMs (Figure 2) and the catalytic features specific to transition metals.

POMs in water column filters and/or in porous organic-inorganic composites proved to be effective in the removal of toxic heavy metals, aromatic organic pollutants, and bacteria (Figures 4, 5 and 7). POMs in porous nanosheets are capable of the photocatalytic degradation of emergent pollutants, particularly antibiotics (Figure 8, Tables 1 and S2), with enhanced photocatalytic performance under visible light (Figure 9), but also dyes, plastics, industrial chemicals, and pesticides (Tables 1 and S2). Moreover, a magnetic core enclosed by polyoxometalate-based ionic liquid phases (Figure 12) was used to remove dyes, heavy metals, microbes, and microplastics (MPs). MPs are not only one of the new emergent health pollutants but also a major one of worldwide concern, in addition to being associated with joint contamination with heavy metals.

POMs, alone and/or in combination with other compounds, such as metal-organic frameworks (MOFs), carbon nanotubes (CNTs) and mesoporous silica supports, have shown promising results in the removal of air pollutants from fossil fuels due to their selective catalytic properties for the oxidation of sulfur compounds (Figures 13, 14, and 15, Table S1). In addition, toxic gases such as hydrogen sulfide, nitrogen oxides and sulfur dioxide are efficiently removed by POMs (Figure 16, Table 2), whereas the volatile organic compounds' reaction mechanism involves a photocatalytic oxidation catalyzed by the $\text{PW}_{12}/\text{g-C}_3\text{N}_4$ hybrid material (Figure 17).

The immobilization of POMs on different supporting surfaces facilitates their electrochemical properties for sensor application (Figure 19, Table 3). Conversely, their variable redox activities and outstanding electron/proton transport capacities make POM-based composite materials suitable for use in electrochemical fields as an exceptional electrode component for supercapacitors and batteries (Table 4). A high-performance pseudocapacitor was obtained by replacing multiple Mo centers in $[\text{H}_3\text{PMo}^{\text{VI}}_{12}\text{O}_{40}]$ with vanadium and incorporating modified a phosphomolybdate with a conducting polymer for improved electrochemical activity (Figure 20), whereas a biomass-derived pinecone activated carbon, that includes POMs contributed to a high specific capacitance (Figure 21). Carbon nanostructures, graphene oxide/reduced graphene oxide, and activated carbon composites come into play as supporting elements for the POMs as they provide better mechanical and electrochemical stability for broader electrochemical applications (Figures 22 and 23). Although this review does not reveal everything, it may help to get closer to viable solutions for the effective use of the POM-based materials for the removal of the

environmental pollutants. The future is bright for POM applications in environmental treatments!

Notes and references

Abbreviations. Ac, acetic acid; AC, activated carbon; AOP, advanced oxidation process; APTMS, 3-aminopropyltrimethoxysilane; APTS, γ -aminopropyltriethoxysilane; Asp, aspartic acid; Bbi, 1,1'-(1,4-butanediyl)bis(imidazole); BE, berberine; bimb, 1,4-bis(1-imidazolyl)benzene; bipy, bipyridine; BMIM or bmim, 1-butyl-3-methylimidazolium; BPA, bisphenol A; BPA-Br, bromobisphenol-A; BPy, 1-butylpyridinium or N-butylpyridinium; BR46, basic red 46; BT, benzothiophene; BTC, 1,3,5-benzenetricarboxylate; CCNF, carbonized cellulose nanofiber; CNTs, carbon nanotubes; CP, chlorphenole; 4-CP, 4-chlorophenole; CPF, ciprofloxacin; CPBPY, N-(3-carboxyphenyl)-4,4'-bipyridinium; cpt, 4-(4'-carboxyphenyl)-1,2,4-triazolate; CSH, cellulose propylamine-modified silica; CTS, chitosan; CV, crystal violet; DBP, di-n-butyl phthalate; DBT, dibenzothiophene; DESs, deep eutectic solvents; DMDBT, 4,6-dimethyldibenzothiophene; DODA-Br, dimethyldioctadecylammonium bromide; DODMAC, dimethyldioctadecylammonium chloride; ECSA, electrochemically active surface area; EDA-CD, per-(6-deoxy-6-iodo)- β -cyclodextrin; ELSA, electrochemically active surface area; en, ethylenediamine; EPs, emergent pollutants; EtOH, ethanol; etpy, 4-ethylpyridine; EY, eosin Y; g-BN, graphene-like hexagonal boron nitride; GA, graphene aerogel; GO, graphene oxide; Gr, graphene; HOMO, highest occupied molecular orbital; HPW or PW_{12} , $[\text{H}_3\text{PW}^{\text{VI}}_{12}\text{O}_{40}\cdot 6\text{H}_2\text{O}]$; $\text{H}_2\text{pyttz-I}$, 3-(pyrid-2-yl)-5-(1H-1,2,4-triazol-3-yl)-1,2,4-triazolyl; $\text{H}_2\text{pyttz-II}$, 3-(pyrid-4-yl)-5-(1H-1,2,4-triazol-3-yl)-1,2,4-triazolyl; H_3bdpm , 1,1'-bis(3,5-dimethyl-1H-pyrazolatemethane); IBA, isobutyraldehyde; IBAC, isobutyric acid; IBP, ibuprofen; IL, ionic liquid; imi, imidazole; iPAF-1, porous aromatic framework; LIBs, lithium-ion batteries; LDH, layered double hydroxide; LMCT, ligand to metal charge transfer; LPMS, large-pore mesoporous silica; LRSR, liquid-redox sulfur recovery; LUMO, lowest unoccupied molecular

- orbital; MB, methylene blue; MBT, 2-mercaptobenzothiazole; MCM-41, conventional molecular sieve MCM-41; MeCN, acetonitrile; MeOH, methanol; mepy, 4-methylpyridine; MO, methyl orange; MOFs, metal-organic frameworks; MOG, metal-organic gel; MPs, microplastics; MR, methyl red; M-TCS, methyl triclosan; NAD, 2-(1-naphthyl)acetamide; NBZ, nitrobenzene; NFZ, nitrofurazone; NPs, (metal) nanoparticles; ODS, oxidative desulfurization; PANI, polyaniline; PBV, patent blue V; pca, pyridine-2-carboxylic acid; PDDA, poly(diallyldimethylammonium chloride); PEI, polyetherimide; phen, 1,10-phenanthroline; PIL, protic ionic liquid; PMIn, polyionene; PMOE, (ethylene-bridged) periodic mesoporous organosilica; PMs, particulate matters; POM, polyoxometalate; POMCP, POM-based coordination polymer; POM-IL, polyoxometalate-based ionic liquid; POMos, polyoxomolybdates; POM-SILP, polyoxometalate-supported ionic liquid phase; POT, polyoxotungstate; PPI, proton pump inhibitor; PPy, polypyrrole; PS, ponceau S; PTMS, 3-aminopropyl trimethoxysilane; PVA, polyvinyl alcohol; PVDF, polyvinylidene fluoride; py, pyrene; PyPS, 3-(pyridine-1-ium-1-yl)propane-1-sulfonate; PZC, point-of-zero charge; RB, rose bengal; RB5, reactive black 5; RhB, rhodamine B; RH, rice husk; rGO, reduced graphene oxide; SAB, sodium-activated bentonite; SBA-15, aminosilylated silica; SC, supercapacitor; SCR, selective catalytic reduction; SDV, sodium decavanadate; SMT, sulfamethazine; SPD, sulfapyridine; SPME, solid-phase microextraction; SSA, 5-sulfosalicylic acid; SSZ, sulfasalazine; SWCNTs, single-walled carbon nanotubes; TB, toluidine blue; TBA, tetra-n-butylammonium ion; TBBA, tetrabromobisphenol-A; TC, tetracycline; TCS, triclosan; TCY, tetracycline; TMA, *N*-trimethoxysilylpropyl-*N*, *N*, *N*-trimethylammonium; TMR4A, resorcin[4]arene-based ligand; TOA, tetraoctylammonium; TPD-MS, temperature-programmed desorption-mass spectroscopy; VOCs, volatile organic compounds; 4,6-DMDBT, 4,6-dimethyl dibenzothiophene; [mim(CH₂)₃COO], 1-carboxypropyl-3-methyl imidazole; [C₄mim]⁺, 1-butyl-3-methylimidazolium ion; β-EDA-CD, per-6-deoxy-6-ethylenediamine-β-cyclodextrin.
