The effect of quercetin on endothelial cells is modified by heterocellular interactions

Sarka Tumova, ^{a,b} Michael J. Houghton ^{a,c} and Gary Williamson ^{*a,c}

Single cell-type models are useful for determining mechanisms, but *in vivo*, cell–cell interactions are important, and neighbouring cells can impact endothelial cell function. Quercetin can attenuate endothelial dysfunction by modulating vascular tone and reducing inflammation. We determined the effect of quercetin on a co-culture between Human Umbilical Vein Endothelial Cells (HUVEC) and human HepG2 hepatic cells or human LHCN-M2 muscle cells. Heme oxygenase-1 (HO-1) mRNA and protein were decreased, pyruvate dehydrogenase kinase (PDK) 4 and glucose transporter (GLUT) 3 mRNA increased, and GLUT1 protein decreased in HUVEC when cultured with HepG2. GLUT transporters, but not the other targets, were similarly regulated in co-culture with muscle cells. Some but not all of the effects were mediated by lactate and transforming growth factor β 1. Quercetin added apically to the endothelial cells upregulated HO-1 and downregulated PDK4 both in monoculture and in co-culture, but the total PDK4 levels were higher in the presence of HepG2 cells. In the absence of general permeability changes, glucose transport across the endothelial monolayer was elevated in the presence of HepG2 cells, however this effect was moderated by quercetin applied on the apical side of the endothelial cells. At lower glucose concentration, apical quercetin also promoted glucose uptake in HepG2 cells. Co-culturing HUVEC with the HepG2 cells showed capacity to modulate quercetin-elicited changes in endothelial gene transcription and glucose transport.

1. Introduction

Endothelial cells fulfil a range of functions across the vascular beds in the body. They provide an interface between circulating blood and target tissue, provide access to nutrients, exchange gases, regulate blood flow and sustain local signalling to modulate physiological and pathophysiological responses, including inflammation or blood coagulation.^{1–3} Endothelial cell functionality is partly governed by the type of vessel, depending on whether they line artery, vein or capillary and, in particular for the latter, depends on the tissue micro-environment, which determines critical parameters such as mechanical forces and oxygen tension as well as hormonal and growth factor regulation. The properties of endothelial cells are finely tuned to their specific location⁴ and, starting from their emergence during development, they help to establish tissue-specific signalling and organ formation,⁵ promote regeneration⁶ and contribute to metabolic homeostasis in the tissues.⁷ Endothelium integrates signalling elicited by the cir-

culating cells and molecules with the feedback from the adjacent tissues in order to secure adequate supply of nutrients and provide capacity for efficient organ maintenance and function.⁸ The context of the nascent environment can have a significant impact and is indispensable for endothelium-specific phenomena such as the nitric oxide (NO) mediated vasorelaxation, where the signalling between endothelial and smooth muscle cells in larger vessels is critical for the regulation of blood pressure.⁹ Similarly, the presence of astrocytes and pericytes is critical for blood-brain barrier integrity and maintenance.¹⁰ The communication between neighbouring cell types in capillaries can regulate endothelial cell proliferation and angiogenesis, and control access of growth factors and hormones to the tissues, as demonstrated for delivery of insulin to the skeletal muscle^{11,12} or modulation of hepatic regeneration and fibrosis.¹³ At the same time, interactions with cells in underlying tissues can modulate the effects of circulating molecules on the endothelial cells.

Diet-derived small molecules such as polyphenols and their metabolites that circulate in the blood affect various aspects of endothelial function post-prandially. Intervention and epidemiological studies have found positive association of polyphenol-rich food with cardiovascular health benefits, including decrease in inflammatory markers and improved blood pressure.^{14–16} Further *in vitro* and animal studies attributed

these benefits to pathways that improve redox balance and reduce inflammation,¹⁷ specifically *via* modulating endothelial nitric oxide synthase (eNOS) function, inhibiting NADPH oxidases (NOX) and other reactive oxygen species (ROS)-generating enzymes and stimulation of nuclear factor erythroid 2-related factor 2 (Nrf2) pathways.^{18,19} One of the best studied polyphenols is the flavonoid quercetin, with specific protective effects on the vasculature described in animal and *in vitro* studies. It can alleviate some consequences of atherogenic and inflammatory signalling, including endothelial damage induced by oxidized low-density lipoprotein (oxLDL) or angiotensin II, by activating SIRT1 and modulating NOX/eNOS activities,²⁰ or by decreasing NOX subunit.^{21,22} In the ApoE^{-/-} mouse model, quercetin attenuates atherosclerosis and improves NO bioavailability through heme oxygenase 1 (HO-1) regulation.²³ It also improves redox balance by regulating oxidation, conjugation and export of glutathione in human aortic endothelial cells.²⁴ Quercetin regulates blood pressure in rats and humans *via* local deconjugation of the plasma metabolite quercetin glucuronide.^{25,26} Quercetin can also downregulate adhesion molecules that attract monocytes during inflammation, such as vascular cell adhesion molecule 1 (VCAM1) or intercellular adhesion molecule 1 (ICAM1),^{27,28} and decrease attachment of monocytes to endothelial cells *via* Nrf2 activation.²⁹ We have reported recently that quercetin can affect endothelial cell metabolism through hypoxia induced factor 1 α (HIF1 α) and the Nrf2 pathway.³⁰ However, despite the fact that the endothelium *in vivo* functions as a part of a larger system, most of the *in vitro* models rely on single-type cell cultures.

In order to examine the impact of other cells on quercetin modulation of endothelial function to better mimic *in vivo* conditions, here we have used HUVEC as a model in non-contact co-cultures and studied the endothelial gene expression and glucose uptake and transport with and without quercetin. HUVEC were cultured in the presence of HepG2 cells or immortalized primary skeletal muscle cells to elucidate the impact on selected gene expression, and then the effects of plant-derived polyphenol quercetin on HUVEC were examined in mono-culture and co-culture with the carcinoma cells.

2. Methods

2.1 Cell culture and co-culture

HUVEC (Lonza Sales Ltd, Switzerland) were cultured in endothelial growth medium 2 (EGM-2) supplemented with EGM-2 BulletKit (Lonza) and used between passage 3–6. HepG2 cells (ATCC cat# HB-8065, LGC Promochem, Teddington, UK) were cultured in Eagle's Minimum Essential Medium supplemented with 10% (v/v) heat-inactivated fetal bovine serum (FBS), 100 U ml⁻¹ penicillin, 100 mg ml⁻¹ streptomycin, 2% (v/v) non-essential amino acids, and 1% (v/v) sodium pyruvate (all from Sigma-Aldrich, Gillingham, UK). Muscle cells were immortalized skeletal muscle cells, LHCN-M2, a gift of Dr Vincent Mouly (Sorbonne Université, INSERM, Institute of Myology,

Centre of Research in Myology, Unite Mixte de Recherche Scientifique 974, Paris, France).³¹ They were cultured in Dulbecco's Modified Eagle Medium (DMEM) (Gibco, Life Technologies, ThermoFisher, UK) supplemented with 5.5 mM glucose, 10% (v/v) FBS (heat-inactivated), 10% v/v heat-inactivated newborn calf serum (Gibco), hEGF (10 μ g L⁻¹; PeproTech, London, UK), hbFGF (1 μ g L⁻¹; Gibco) and dexamethasone (400 μ g L⁻¹) (Sigma), as described previously.³² Myocytes were differentiated upon confluency by switching to a differentiation medium (5.5 mM glucose in DMEM, 2% horse serum (Gibco)) for up to 4 days.³² For the co-cultures, HUVEC were seeded on semi-permeable membrane supports in 6-well (2 \times 10⁵ cells per well) Transwell plates (Corning, New York, USA). After 3 days, membrane inserts with the HUVEC monolayers were transferred on top of wells in 6-well plates with nearly confluent HepG2 cells or 3-day differentiated LHCN-M2 muscle cells, using 0.2% FBS in EGM-2 as the basal and apical medium, and the cells were co-cultured for a further 24 h. Alternatively, after 1 h incubation, the medium on apical side was replaced with fresh 0.2% FBS in EGM-2 with 5 μ M quercetin or 0.01% DMSO and the cells were further incubated for 18 hours. At the end of the co-culture, monolayer *trans*-endothelial electrical resistance (TEER) was measured using a Millicell ERS voltohmmeter (Millipore (UK) Ltd, Watford, UK) according to the manufacturer's instructions. After that, the cells were harvested or the glucose uptake assays were performed as described below. The quercetin (Extrasynthese, Genay, France) stock was prepared at 50 mmol L⁻¹ in DMSO and diluted to the final concentration of 5 μ mol L⁻¹ for the treatments. DMSO was used at 0.01% in the corresponding control. For TGF β 1 treatment, human recombinant TGF β 1 (Sigma) was applied to the cells in the EGM-2 medium at 50 ng ml⁻¹.

2.2 Glucose uptake and transport

Cells were washed with glucose-free buffer (2.5 mM MgCl₂, 1 mM CaCl₂, 0.14 M NaCl, 20 mM HEPES, 3.5% NaHCO₃, pH 7.3), incubated for 10 min in glucose-free RPMI medium and then supplemented for 10 min with 5.5 mM D-[¹⁴C(U)]-glucose (0.1 μ Ci ml⁻¹) (PerkinElmer, Seer Green, UK) on the apical side. Radioactive medium on the apical and basolateral side was collected and the radioactivity measured by scintillation counting. The cells were washed three times with cold PBS with Ca²⁺ and Mg²⁺, lysed in 1 M NaOH and radioactivity in the cell lysate aliquot, neutralized with 1 M HCl, was determined by scintillation counting. Measured radioactivity was converted to glucose concentration using standard calibration curves constructed using medium with known amounts of ¹⁴C-labelled glucose. Small aliquots of cell lysates were used to measure protein content by Coomassie Protein Assay (Pierce, Thermo Fisher Scientific, Altrincham, UK) and uptake corrected for protein content.

2.3 mRNA quantification by droplet digital PCR (ddPCR)

The ddPCR was performed using cDNA obtained by reverse transcription (high capacity RNA-to-cDNA kit, Life

Technologies) from mRNA, isolated from cell lysates (AurumTM-Total RNA Mini kit, Bio-Rad Laboratories Ltd, Herts, UK) as recommended by the standard manufacturer's protocols. Guidelines for digital PCR³³ were followed as appropriate. FAM-labelled gene-specific probes were from Bio-Rad: glucose transporter (GLUT)1 (SLC2A1), dHsaCPE5035286; and Life Technologies: GLUT3 (SLC2A3), Hs00359840_m1; GLUT6 (SLC2A6), Hs01115485_m1; HO-1, Hs01110250_m1; ATP binding cassette subfamily B member 1 (ABCB1) Hs00184500_m1; ATP binding cassette subfamily C member 2 (ABCC2), Hs00166123_m1; ATP binding cassette subfamily G member 2 (ABCG2), Hs01053790_m1; monocarboxylate transporter (MCT)1 (SLC16A1), Hs00161826_m1; MCT4 (SLC16A3), Hs00358829_m1; MCT5 (SLC16A4), Hs00190794_m1; pyruvate dehydrogenase kinase (PDK) 2, Hs00176865_m1; PDK4, Hs01037712_m1. TATA binding protein (TBP) was used as a reference for mRNA quantification using VIC-labelled probe (TBP, Hs00427620_m1, Life Technologies). Samples corresponding to 10–15 ng mRNA were analysed for specific gene expression using QX100 Droplet Digital PCR system (Bio-Rad) as described previously.³⁴ Briefly, the PCR reaction mix with the gene-specific fluorescent probes was dispersed into oil droplets using QX-100 Droplet Generator. After 40 cycles on the X1000 Touch, droplets were analysed by QX100 Droplet Reader. QuantaSoft software (Kosice, Slovakia) was used to analyse the data and determine the number of copies present in the mix, which were then expressed as the relevant mRNA/TBP ratio, or converted to copies per ng of mRNA, assuming 1 : 1 RT PCR efficiency.

2.4. Protein detection by simple western

GLUT1, GLUT3, HO-1 and Galectin1 protein levels were detected by automated capillary western blotting on WES (ProteinSimple, Bio-Techne, San Jose, CA, USA). At the end of the co-culture, HUVEC on filters were washed in cold PBS and lysed in 60 mM octyl-glucoside, 150 mM NaCl, 20 mM Tris, pH 7.4 with protease inhibitors. Standard conditions for the western protocol were followed as recommended by the manufacturer, except the incubation with the primary antibodies was extended to 60 min. Rabbit antibodies against GLUT1 (dilution 1 : 50; Abcam, cat# ab115730, RRID:AB_10903230) and GLUT3 (dilution 1 : 100; Abcam, cat# ab191071, RRID:AB_2736916) were used with rabbit anti-Na,K-ATPase (dilution 1 : 50; Cell Signaling Technology, New England Biolabs (UK) Ltd, Hitchin, UK, cat# 3010 RRID:AB_2060983) for a loading control, with denaturation performed for 20 min at 37 °C to prevent aggregation. Goat anti-HO-1 (20 µg ml⁻¹, R&D Systems, Bio-Techne, cat# AF3776, RRID:AB_2295362) was used for detection with anti-calnexin (8 µg ml⁻¹, Santa Cruz Biotechnology, Dallas, TX, USA, cat# sc-6465, RRID:AB_2069146) as the loading control and the standard denaturation protocol for 5 min at 95 °C was followed for the sample preparation. Galectin-1 was detected with mouse monoclonal antibody (dilution 1 : 20; Novus Biologicals, Bio-Techne, cat# MAB1152, RRID:AB_2811716) using rabbit anti-α-actinin D6F6 antibody (1 : 50; Cell Signaling Technology,

NEB, cat# 6487, RRID:AB_11179206) as a control. Incubation with anti-goat-IgG-HRP (dilution 1 : 25; R&D Systems), anti-rabbit-IgG-HRP (ProteinSimple, Bio-Techne), or anti-mouse-IgG-HRP with 20× anti-rabbit-IgG-HRP (ProteinSimple, Bio-Techne) followed by luminol/peroxide was used to generate the chemiluminescent signal for quantification. All sets of antibodies gave a linear response in the range between 0.1–0.4 mg protein per ml and 0.2 mg ml⁻¹ was selected for the GLUT and Galectin-1 analysis, while 0.4 mg ml⁻¹ was used for HO-1.

2.5. TGFβ1 ELISA

Nearly confluent HepG2 cells or 3-days differentiated LHCN-M2 cells were incubated with 0.2% FBS in EGM-2 medium for 19 h. Conditioned medium was centrifuged for 10 min at 600g and aliquots were stored frozen at –80 °C until use. Total secreted TGFβ1 was quantified after activation of the latent form, using Dual TGFβ1 Quantikine ELISA (R&D Systems, Bio-Techne) according to the manufacturer's instructions. The EGM-2 medium with 0.2% FBS, which contained less than 31 pg ml⁻¹ TGFβ1, was used as a blank. The measured values were within the linear range of the calibration curve (31–1000 pg ml⁻¹) for the recombinant TGFβ1 provided by the manufacturer.

2.6. Lactate quantification

Lactate in the cell medium was detected and quantified by High Performance Anion Exchange Chromatography with Pulsed Amperometric Detection (HPAE-PAD) using the Dionex ICS-4000 Ion Chromatography System (Thermo Scientific). After treatments, medium was removed from the cell monolayers and centrifuged at 1000g to remove cellular debris. Cell-free medium was deproteinized by adding an equal volume of ACN, incubating on ice for 5 min and centrifuging for 10 min at 18 000g at 4 °C. The sample was diluted 50-fold in MilliQ water to fall within the linear range of lactate detection (1–20 µg ml⁻¹) and applied on the Dionex IonPac AS11 (Thermo Scientific) anion exchange column, equilibrated in 1 mM KOH, and a 1–60 mM KOH gradient was used for elution. A standard calibration curve was obtained from linear range of concentrations of ICE standard lactate (Sigma).

2.7. Data analysis

Test and control data obtained in pairs were compared using independent Student *t*-test. ANOVA with Bonferroni *post-hoc* analysis was used for sets with multiple samples. Differences with *p* < 0.05 (*) were considered significant. All results were obtained from at least 2–3 independent experiments. Origin software (OriginLab Corporation, Northampton, MA, USA) was used for data analysis and the data are presented as mean ± SEM.

3. Results

3.1 Co-culturing HUVEC with HepG2 or muscle cells affects differently endothelial gene expression

To establish the impact of HepG2 cells on endothelial cell expression of glucose, anion and drug transporters and metabolism-related genes, confluent HUVEC on Transwell inserts were cultured for 24 h with or without HepG2 cells on their basolateral side. This affected the mRNA expression of several endothelial genes (Fig. 1A), including significant increases in GLUT3 (236 ± 32% of the control) and PDK4 (229 ± 21% of the control), and decreases in GLUT6, MCT1 and HO-1 (66.7 ± 15.7%, 91.0 ± 1.5% and 29.7 ± 4.5% of the control, respectively), while the expression of the other tested genes remained unchanged. The downregulation of HO-1 was confirmed at the protein level (72.9 ± 7.7% of the control) (Fig. 1B), but the upregulation of GLUT3 mRNA did not translate to a significant increase in protein (Fig. 1B). On the other hand, protein levels of endothelial GLUT1 were almost halved (52.5 ± 4.8% of the control) in the co-culture even in the absence of mRNA changes (Fig. 1B), indicating involvement of posttranscriptional regulation. Galectin-1 expression has been previously

reported to change in endothelial co-cultures, but galectin-1 protein levels were similar between the HUVEC monoculture and co-culture (Fig. 1B). Some of the observed effects were specific for HepG2 cells, as HUVEC co-culture with differentiated skeletal muscle cells affected endothelial mRNA and protein levels differently (Fig. 2A and B). GLUT3 mRNA was still significantly increased in the co-culture (183 ± 18.5% of the control), but in contrast to the HepG2 co-cultures, GLUT6, MCT1, PDK4 and HO-1 mRNA remained unaffected, while GLUT1 mRNA was downregulated by about 20% (80.9 ± 7.9% of the control). At the protein level, similar to the effect on HepG2 cells, the co-incubation with muscle cells triggered GLUT1 downregulation (63.1 ± 3.0% of the control), while GLUT3 and galectin-1 were not affected. However, in contrast to the HepG2, muscle cells did not affect the endothelial HO-1 protein levels (Fig. 2B).

3.2 The effects of HepG2-conditioned media on HUVEC gene expression

One of the most prominent features of HepG2 metabolism is lactate production. In the current setting, the lactate concentration in the media was measured by HPAE-PAD chromato-

Fig. 1 Gene expression in HUVEC co-culture with HepG2 cells. Confluent HUVEC were cultured on Transwells alone (control) or in the presence of confluent HepG2 cells on the basolateral side (HepG2 co-culture) in BulletKit-supplemented EGM-2 medium. After 24 h, the mRNA expression was analysed by ddPCR (A) and the protein expression for selected genes was determined using automated capillary Western analysis (B). The monolayer integrity was verified by TEER measurement (C). NS, not significantly different.

Fig. 2 Gene expression in HUVEC co-culture with muscle cells. Confluent HUVEC were cultured on Transwells alone (control) or in the presence of differentiated LHCN-M2 cells on the basolateral side (LHCN-M2 co-culture) in 0.2% FBS EGM-2 medium. After 19 h, the mRNA expression was analysed by ddPCR (A) and the protein expression for selected genes was determined using automated capillary Western analysis (B). The monolayer integrity was verified by TEER measurement (C). NS, not significantly different.

Fig. 3 Extracellular lactate concentration in the HUVEC cultures with and without HepG2 cells. Lactate detection by ICS-4000 ion capillary system was linear in the range between 1–20 $\mu\text{g ml}^{-1}$ (A). Lactate was detected in 100-fold diluted basolateral media from HUVEC cultured alone or in the presence of HepG2 cells for 24 h (B). Lactate concentration in undiluted co-culture medium was estimated to be 8.3 ± 0.3 mM, while the lactate concentration produced in HUVEC monoculture was 1.1 ± 0.1 mM.

graphy and was estimated to reach 8.3 ± 0.3 mM at the end of the 24 h co-culture (Fig. 3), a significant increase compared to 1.1 ± 0.1 mM lactate measured in corresponding HUVEC monoculture. To test whether the additional lactate or other factors secreted by HepG2 cells into the basolateral medium could be responsible for the observed gene expression changes, HUVEC were cultured for 18 h in the presence of 8 mM lactate, HepG2-conditioned medium, or HepG2 cells on the basolateral side and the mRNA for MCT1, PDK4 and HO-1 was detected by ddPCR (Fig. 4A, B and C). A small effect of lactate or conditioned media was observed on PDK4 and HO-1 mRNA expression (Fig. 4B and C), but did not reach the magnitude of the changes triggered by HepG2 cell co-culturing. The time-course of the mRNA expression for MCT1, PDK4 and HO-1 was further followed in HUVEC incubated with 8 mM lactate for 1, 3, 6 and 24 h (Fig. 5). Lactate transiently decreased PDK4 and MCT1 mRNA levels while HO-1 mRNA declined steadily with maximum decrease of $\sim 30\%$ after 24 h. This indicates that time-dependent changes in lactate concentration may contribute to MCT1 and HO-1 regulation, but are not solely responsible for the full effect.

3.3. The role of TGF β 1 secreted by HepG2 cells in the HO-1 downregulation

One of the few known negative regulators of HO-1 expression is TGF β 1.³⁵ In agreement, incubation with human recombi-

Fig. 4 Effect of culture conditions on gene expression. HUVEC were cultured in the presence of 8 mM lactate, conditioned HepG2 media or HepG2 cells. After 18 h, the expression of MCT1 (A), PDK4 (B) and HO-1 (C) mRNA was determined by ddPCR.

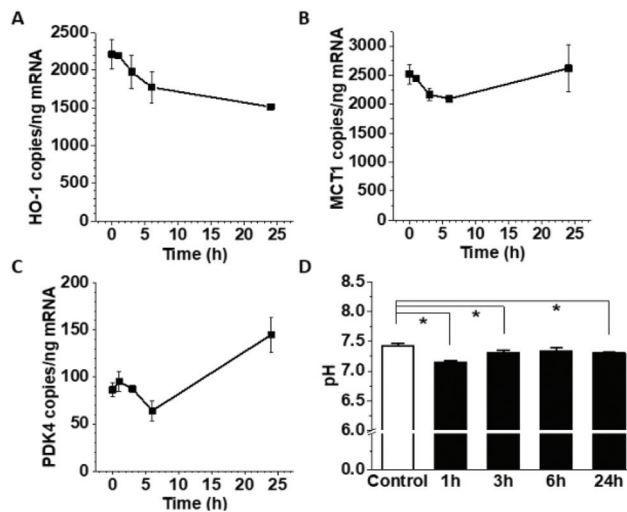

Fig. 5 The effect of pH/lactate on gene expression in HUVEC. Confluent HUVEC on Transwells were exposed to 8 mM lactate on the basolateral side for 1, 3, 6 and 24 h and mRNA for HO-1 (A), MCT1 (B), and PDK4 (C) was measured by ddPCR. The pH was monitored after lactate addition and compared to untreated control medium (D).

nant TGF β 1 decreased HO-1 mRNA expression in HUVEC (Fig. 6A). HepG2 cells secreted a significant amount of TGF β 1 in the media (Fig. 6B), which could contribute to HO-1 down-

Fig. 6 TGFβ1 and HO-1 expression in HUVEC. Confluent HUVEC were incubated with recombinant TGFβ1 for 24 h and the HO-1 expression was analysed by ddPCR (A). TBP was used for normalization. TGFβ1 ELISA was used to measure the growth factor secretion in confluent LHCN-M2 muscle cells (LHCN-M2_c) and subconfluent (HepG2_s) and confluent (HepG2_c) HepG2 cells (B). The growth factor secretion was normalized to the cell area.

regulation. Considerably lower amounts of TGFβ1 were detected in the muscle-conditioned media, consistent with their lack of effect on HO-1 expression in HUVEC.

3.4. Effects of quercetin on HO-1 and PDK4 expression in HUVEC in the presence and absence of HepG2 cells

We have shown previously in HUVEC that incubation with quercetin dramatically upregulated HO-1 mRNA at 4 h while decreasing PDK4 mRNA expression at 18 h.³⁰ As both genes were significantly affected by co-culturing with HepG2 cells, we have tested the impact of quercetin in the co-culture. Quercetin was applied to the apical side of HUVEC during the culture in the presence and absence of HepG2 cells and the mRNA for HO-1 and PDK4 was analysed after 4 or 18 h. Compared to untreated cultures, incubation with quercetin for 4 h significantly upregulated HO-1 mRNA in both monoculture ($160 \pm 11\%$) and co-culture ($214 \pm 35\%$) (Fig. 7A), consistent with the previous work.³⁰ In contrast to the longer, 24 h incubation (Fig. 1A and 4C), there was no significant effect of co-culturing on the HO-1 mRNA level at 4 h. At 18 h, the HUVEC PDK4 mRNA was significantly downregulated by quercetin in monoculture as well as co-culture (77.4 ± 2.8 and $85.9 \pm 2.8\%$, of the respective untreated controls), but because of the PDK4 upregulation in the co-culture ($182.8 \pm 3.3\%$), the absolute PDK4 levels in the quercetin-treated co-culture were signifi-

Fig. 7 Effect of HepG2 cells on gene expression in HUVEC. Gene expression changes in HUVEC cultured with or without HepG2 cells were measured in the presence or absence of 5 μM quercetin. Confluent HUVEC and 80% confluent HepG2 cells were co-cultured for 1 h in 0.2% FBS EGM-2 medium on Transwells in parallel to control HUVEC. Medium with or without 5 μM quercetin was then added to the apical side and the cells were further incubated for 4 (A) or 18 h (B). The mRNA expression of HO-1 (A) and PDK4 (B) was detected by ddPCR and normalized to the relevant monoculture control.

cantly higher (~2-fold) than in monoculture (Fig. 7B). Thus, the effects elicited by co-culturing did not reverse, but rather modulated quercetin-induced changes in PDK4 expression, and did not significantly affect the short-term HO-1 upregulation.

3.5. Glucose transport in HUVEC co-cultures

To determine whether co-culture with HepG2 cells affects glucose uptake and transport by HUVEC, cells seeded on Transwells were cultured alone or with HepG2 cells in the presence or absence of 5 μM quercetin on the apical side, and then D-[¹⁴C(U)]-glucose transport was measured. There were no changes in the monolayer integrity as measured by the TEER (Fig. 8A). Compared to the monoculture, HUVEC in co-culture incubated with 5 mM glucose transported less D-[¹⁴C(U)]-glucose across the monolayer, and this effect was slightly alleviated in the presence of quercetin (Fig. 8B). No statistically significant effect was observed for the glucose uptake in the HUVEC or HepG2 cells. Depending on the role of different glucose transporters in the uptake, the effects could be modulated by the total glucose levels in the uptake assay and so we tested lower glucose concentration in the transport/uptake solution. When 0.5 mM glucose was used in the HUVEC-HepG2 co-culture, quercetin pre-incubation significantly increased the glucose uptake in the HepG2 cells, but not in the HUVEC (Fig. 8C). At this concentration, the trans-

Fig. 8 The effect of quercetin on glucose uptake and transport in HUVEC and HepG2 cell co-cultures. Confluent HUVEC were incubated with or without HepG2 cells on the basolateral side for 1 h, then medium with or without 5 μ M quercetin was added to the apical side and the cells were cultured for 18 h. The HUVEC monolayer integrity was checked by measuring TEER (A). Glucose transport was estimated by applying 5 mM D-¹⁴C(U)-glucose (0.1 μ Ci ml⁻¹) on the apical side and after 10 min, the distribution of ¹⁴C-label was measured in the apical, basolateral and cellular compartments (B). HUVEC-HepG2 co-cultures treated for 18 h with or without 5 μ M quercetin were incubated for 10 min with 0.5 mM D-¹⁴C(U)-glucose on the apical side and the uptake for both HUVEC and HepG2 cells was determined from the radioactivity measured in cell lysates (C).

port across the monolayer was not significantly affected (data not shown).

4. Discussion

Food-derived polyphenols have been studied as candidates for interventions to lower the risk of type 2 diabetes, based on their reported ability to regulate glucose absorption and metabolism and alleviate endothelial dysfunction. The mechanism of these activities has been explored through numerous *in vitro*, animal and human studies. In recent years, a limited number of co-culture cell models have been used to investigate some aspects of polyphenol metabolism and signalling.³⁶ For example, co-cultures of Caco2 enterocytes and HT29-MTX goblet cells were used to study polyphenol transport and conjugation.³⁷ Protective effects of polyphenols during inflammation have been elucidated in models combining macro-

phages and gingival fibroblasts³⁸ or adipocytes,³⁹ or monocytes and Caco-2 cells.⁴⁰ Other studies explored anti-inflammatory potential of anthocyanins in co-cultures of gingival epithelial cells and fibroblasts⁴¹ or epithelial and endothelial cells.^{42,43} Recently, quercetin was shown to attenuate apoptosis of pancreatic β -cells through NO signalling in endothelial cells.⁴⁴ However, our comprehension of the interplay between different cells in similar systems is still limited. Therefore, here we aimed to extend our previous study on the impact of quercetin on endothelial cell metabolism³⁰ by including liver cells in the model, in order to examine the potential role of microenvironment and paracrine messengers. Different aspects of the interaction between endothelial and liver cells have been studied previously in organoids and systems combining endothelial cells with hepatocytes or HepG2 cells.⁴⁵⁻⁴⁷ HepG2 cells were shown to regulate lymphocyte transmigration across sinusoidal endothelial cells.⁴⁸ Several studies addressed the communication *via* soluble factors including vesicles,⁴⁹ although physical contact between HUVEC and HepG2 cells was required for angiogenic stimulation.⁵⁰ *In vivo*, liver endothelial cells form a discontinuous, fenestrated layer, and are separated from the other liver cells by a thin Disse space, allowing for free exchange of soluble and other factors. Therefore, we have investigated the impact of liver cells on intact mature endothelial monolayers by utilizing a contact-free co-culture of endothelial and HepG2 cells and further studied the changes in the endothelial gene expression under the combined impact of co-culture and quercetin exposure. Because of the challenges associated with culturing primary hepatocytes, carcinoma-derived HepG2 cells were used as they are well characterized and afford better reproducibility. However, since there are metabolic differences between normal and transformed cells, it is possible that our results are more pertinent to tumour environment than normal tissue. We found that in the presence of HepG2 cells, HUVEC expressed increased levels of PDK4 mRNA and lower levels of GLUT1 and HO-1 protein. The HepG2 cells secreted TGF β 1 and dramatically increased lactate concentration in the medium compared to the HUVEC cultured alone. These and other soluble factors possibly contributed to the observed changes in gene expression, but continuous feedback from HepG2 cells was required for the maximum impact as HepG2-conditioned medium had only limited effect. These were specific to the HepG2 cells as the only detected change in endothelial cells co-cultured with LHCN-M2 immortalized skeletal muscle cells was downregulation of GLUT1 protein. Neither cell line affected the tightness of the endothelial monolayer. Since endothelial HO-1 and PDK4 gene expression has been shown to be significantly affected by quercetin exposure after 4 and 18 h respectively,³⁰ we looked at whether this is altered in the co-culture. HO-1 mRNA was upregulated by 4 h-exposure to quercetin both in monoculture and co-culture. At the same time there were no significant differences between the HO-1 levels in the two settings in the absence of quercetin, most likely because the 4 h-incubation was too short for the full effect of the co-culture to take place.

PDK4 mRNA was upregulated in the co-culture after 18 h, but quercetin decreased the mRNA levels in co-cultured HUVEC to the levels comparable to the untreated cells in monoculture. Thus, although the general impact of quercetin on endothelial expression of PDK4 and HO-1 was similar in endothelial monoculture and co-culture, the presence of HepG2 cells moderated the quercetin effects on PDK4, but not HO-1 expression.

Co-culturing with HepG2 cells decreased the amount of glucose transported across the HUVEC monolayer, possibly related to the GLUT1 downregulation. This was slightly alleviated by quercetin, consistent with our previous finding that quercetin could increase glucose transport in HUVEC. In addition, quercetin application to the apical side of endothelial cells stimulated glucose uptake in HepG2 cells on the basolateral side, but only for low glucose concentration, possibly as a downstream effect of quercetin-triggered signalling. At this quercetin concentration, the amount of the polyphenol transported to the basolateral side of the endothelial monolayer would be quite small, so an indirect effect through HUVEC is more plausible than quercetin acting on the HepG2 directly. Altered expression of glucose or drug transporters as well as changes in ROS and extracellular signalling in the endothelial cells could have a downstream effect on the adjacent HepG2 cells. Thus, in addition to direct effects, polyphenols such as quercetin could act on the target tissues through shifting the redox and metabolic balance in the endothelium and modifying the associated endothelial signalling to the underlying tissues.

5. Conclusions

In summary, we have used endothelial cells in co-culture with HepG2 cells as a more physiologically relevant configuration to study the impact of diet-derived polyphenol quercetin on their physiology. We have shown that the co-culture affects expression of various genes involved in metabolism (GLUT1 and PDK4) or redox balance (HO-1) in HUVEC, which can then contribute to regulating changes triggered by quercetin application, supporting the notion that the local environment in tissues has potential to modulate the impact of circulating molecules.

Abbreviations

ABCB1	ATP binding cassette subfamily B member 1
ABCC2	ATP binding cassette subfamily C member 2
ABCG2	ATP binding cassette subfamily G member 2
ApoE	Apolipoprotein E
ddPCR	Droplet digital PCR
DMEM	Dulbecco's modified Eagle medium
EGM-2	Endothelial cell growth medium 2
eNOS	Endothelial nitric oxide synthase
GLUT	Glucose transporter
HIF1 α	Hypoxia induced factor 1 α

HO-1	Heme oxygenase-1
HPAE-PAD	High performance anion exchange chromatography with pulsed amperometric detection
HUVEC	Human umbilical vein endothelial cells
ICAM1	Intercellular adhesion molecule 1
MCT	Monocarboxylate transporter
NO	Nitric oxide
NOX	NADPH oxidase
Nrf2	Nuclear factor erythroid 2-related factor 2
oxLDL	Oxidized low density lipoprotein
PDK	Pyruvate dehydrogenase kinase
ROS	Reactive oxygen species
SIRT1	Sirtuin 1
TGF β	Transforming growth factor beta
VCAM1	Vascular cell adhesion molecule 1
TBP	TATA binding protein
TEER	Transendothelial electrical resistance

Author contributions

ST and GW conceived and planned the project. ST carried out the experiments and analysed the data with MJH providing assistance with the muscle cell cultures. ST and GW wrote the manuscript and all authors provided feedback and contributed to the final version of the manuscript.

Conflicts of interest

The authors have no conflicts of interest to declare.

Acknowledgements

The presented research has been supported by funding from the European Research Council advanced grant number 322467 ('POLYTRUE?'). We thank Dr Vincent Mouly (Sorbonne Université, INSERM, Paris, France) for providing the immortalized skeletal muscle cells LHCN-M2.
