Transition metal oxides (TMOs) have been playing an indispensible role in the catalysis of redox reactions. In particular, two dimensional TMOs expose their surface/edge sites to a large extent, which brings unique catalytic features such as greatly enhanced catalytic activities. Here a series of MnO_2 nanosheets have been facilely synthesized by a simple redox reaction between $KMnO_4$ and 2-(*N*-morpholino)ethane sulfonic acid (MES) at room temperature. Among the obtained MnO_2 samples, MnO_2-48 h showed the highest performance in removing C_2H_4 resulting from its highest concentration of surface active oxygen species. To further improve the oxidation activity of the catalyst, a small amount of Pt nanoparticles (NPs) was subsequently loaded on MnO_2 nanosheets (Pt/MnO_2) by a colloidal deposition method. The Pt/MnO_2 demonstrated enhanced catalytic performance and maintained complete removal of 20 ppm C_2H_4 at 50 °C for at least 12 h, which can be attributed to the large amount of adsorbed oxygen species and synergetic catalytic effect between Pt and the MnO_2 support.

1 Introduction

Two-dimensional (2D) nanostructured materials have been attracting increasing attention in catalysis, optoelectronics, clean energy and biomedicine,[1–3] thanks to their large surface-to-volume ratio and confined thickness on the atomic scale.[3] Graphene,[4,5] MoS_2,[6] g-C_3N_4 [7,8] and their derivatives are the most widely investigated 2D materials due to their easy preparation and attractive functionalities. Transition metal oxides (TMOs), which show great potential in applications such as catalysis, energy storage, and so on, have been usually obtained in 3D bulk and/or porous nanostructures, nevertheless, low-dimensional nanoclusters/nanodots (0D), nanowires/nanorods (1D) and nanosheets (2D) are arousing rapidly increasing interest. The top-down strategy of chemical or physical exfoliation[9] has made it possible to obtain 2D TMOs. Recently, other strategies have also been developed to fabricate 2D TMOs. For example, by a bottom-up molecular self-assembly process, Sun *et al.*[10] prepared a serious of TMOs such as Co_3O_4, ZnO, WO_3, Fe_3O_4 and MnO_2. However, the massive and low-cost synthesis of 2D nanostructured TMOs is still a great challenge.

As a typical kind of TMOs, manganese oxide is particularly promising thanks to its abundance, environmental friendliness and high catalytic performances in environmental purification and clean energy production, which are active in many reactions like NO oxidation,[11,12] CO oxidation,[13] water oxidation,[14,15] *etc.* Manganese oxides are capable of mobilizing electrons, and thus the necessary mobile-electron environment for catalysis can be built.[16] Birnessite, *i.e.* δ-MnO_2, has a layered crystal structure, which is stacked by layers of edge-sharing MnO_6 octahedra with a certain number of water molecules and different cations (*e.g.* Li^+, Na^+, K^+, Ca^{2+}) between the layers to balance the charge. The unique layered structure of birnessite makes it an efficient catalyst to remove HCHO, CO and volatile organic compounds (VOCs). Zhang *et al.*[17] found that δ-MnO_2 catalyst exhibited better activity in removing 170 ppm formaldehyde at 80 °C than α-, β-, and γ-MnO_2 due to its special 2D layered structure. Despite the high cost, noble metals (*e.g.* Pt) have been loaded on δ-MnO_2 to enhance its catalytic activity and made it possible to remove pollutants at low temperature even at room temperature[18,19] thanks to the strong metal–support interaction (SMSI), or, synergetic catalytic effect,[20] between noble metals and the MnO_2 support.

Ethylene (C_2H_4), a common gaseous organic compound, is widely used as a raw material in chemical industry and is also an important natural plant hormone used in agriculture to force the ripening of fruits. However, it is also a typical harmful VOC

† Electronic supplementary information (ESI) available: The N_2 adsorption–desorption isotherms of the as-synthesized MnO_2 samples and Pt/MnO_2-48 h; XPS Pt 4f spectrum of Pt/MnO_2-48 h; specific surface areas of the as-prepared MnO_2 samples and Pt/MnO_2-48 h. See DOI: 10.1039/c6ra26529d

which will lead to photochemical pollution of the atmosphere and cause anesthetic illness.[21] Consequently, the removal of ethylene contaminant from air under mild conditions is highly significant. C_2H_4 is a typical thermally stable hydrocarbon compound with C–H, C–C σ bonds and C–C π bonds. The high bond energy of C–H bond (413 kJ mol^{-1}) and C=C bond (615 kJ mol^{-1}) make it more difficult to be removed by catalytic oxidation than formaldehyde and CO. Supported noble metals have been proved to be highly effective in catalyzing the oxidation of ethylene at relatively low temperatures.[22,23] Jiang *et al.*[24] found that Pt loaded on MCM-41 showed higher performance to catalytically remove C_2H_4 than other noble metals on the same support.

Herein, we synthesized 2D MnO_2 nanosheets by a simple redox reaction between potassium permanganate ($KMnO_4$) and 2-(*N*-Morpholino)ethane sulfonic acid (MES) at room temperature and subsequently loaded Pt nanoparticles (NPs) *via* colloidal deposition on the obtained MnO_2 nanosheets. The as-prepared Pt/MnO_2 catalyst showed extraordinarily high activity and durability in the catalytic oxidation of ethylene, and the complete ethylene removal has been achieved at around 50 °C for at least 12 h.

2 Experimental section

2.1 Preparation of the catalyst

2.1.1 Chemicals. Potassium permanganate ($KMnO_4$), chloroplatinic acid ($H_2PtCl_6 \cdot 6H_2O$), ascorbic acid, sodium citrate were purchased from Sinopharm Chemical Reagent Co., Ltd.; PVP was purchased from Alfa Aesar Co., Ltd.; 2-(*N*-Morpholino)ethane sulfonic acid (MES) was purchased from Sigma-Aldrich Co. LLC. All the chemicals were used as received.

2.1.2 Material synthesis

2.1.2.1. The synthesis of MnO_2 nanosheets. MnO_2 nanosheets were prepared according to the previous report[25] with little modification. 2.10 g $KMnO_4$ was dissolved in 120 mL deionized water and 4.26 g 2-(*N*-morpholino)ethane sulfonic acid (MES) was dissolved in 120 mL deionized water, respectively. Then the $KMnO_4$ solution was added dropwise into the MES solution under stirring. The resultant mixture was kept stirring for different time at room temperature. Then the brown slurry was filtered and washed with deionized water and alcohol and dried at 80 °C overnight. The obtained samples were denoted as MnO_2-*t*, where t represents the reaction time between $KMnO_4$ and MES.

2.1.2.2. The synthesis of Pt/MnO_2. Pt/MnO_2 catalyst with 2 wt% Pt was prepared by an ascorbic acid reduction method.[26] In a typical procedure, 68 mg of PVP (PVP : H_2PtCl_6 = 20 : 1, molar ratio) and 0.18 g of sodium citrate (sodium citrate : H_2PtCl_6 = 20 : 1, molar ratio) were dissolved in 100 mL deionized water. 0.8 mL aqueous chloroplatinic acid ($H_2PtCl_6 \cdot 6H_2O$) (20 mg mL^{-1}) solution was added dropwise to the above solution under vigorous stirring at 80 °C. After stirring for an additional 5 min, 10 mL aqueous solution with 108 mg of ascorbic acid (ascorbic acid : H_2PtCl_6 = 20 : 1, molar ratio) was added dropwise to the mixture solution and after continual stirring for 1 h, the Pt colloid solution was obtained. Subsequently, 0.3 g MnO_2-48 h powder (dispersed in 50 mL deionized water by ultrasound) was added into the Pt colloid solution. After stirring at 80 °C for 4 h, the obtained precipitate was filtered and washed several times with deionized water and absolute alcohol to remove any possible residual reactants. Finally, the product was dried at 80 °C for overnight and denoted as Pt/MnO_2-48 h.

2.2 Characterizations

Field Emission Transmission Electron Microscopy (FETEM) analysis was conducted with a JEOL 200CX electron microscope operated at 200 kV. Energy dispersive spectrum (EDS) was obtained from an attached Oxford Link ISIS energy-dispersive spectrometer fixed on a JEM-2010 electron microscope. Field Emission Scanning Electron Microscopy (FESEM) analysis was conducted with a Su 8220 electron microscope. Powder X-ray diffraction (XRD) patterns were recorded on a Rigaku D/Max 2200PC diffractometer using Cu-Kalpha radiation (40 kV and 40 mA). The scanning rate was 4° min^{-1}. The content of Pt was measured with Inductively Coupled Plasma atomic emission spectrometry (ICP-OES) (Vista AX). Nitrogen adsorption/desorption isotherms at 77 K were measured on a Micromeritics TriStar 3000 instrument. All samples were outgassed at 150 °C for 12 h under flowing N_2 before the measurement. The specific surface areas were calculated by the Brunauer–Emmet–Teller (BET) methods using the desorption branches. X-ray photoelectron spectroscopy (XPS) signals were collected on VG Micro MKII instrument using monochromatic Mg Kalpha X-ray at 1253.6 eV operated at 120 W. All the element binding energies were referenced to the C (1s) line situated at 284.6 eV. The H_2 temperature-programmed reduction (H_2-TPR) and O_2 temperature programmed desorption (O_2-TPD) measurements were conducted on a pulse chemisorption system (Chemisorb 2750, Micromeritics Inc.) equipped with a TCD detector. As for H_2-TPR, 50 mg sample was loaded into a quartz U-type tube. The sample was first pretreated with He (30 mL min^{-1}) at 80 °C for 1 h and cooled down to the room temperature, then 5% H_2/Ar was introduced with a rate of 25 mL min^{-1} and at the same time the temperature was increased to 800 °C at the rate of 10 °C min^{-1}. For O_2-TPD, the sample was first pretreated with He (30 mL min^{-1}) at 80 °C for 1 h to remove physisorbed and interlayered H_2O as well as surface oxygen. Then it was cooled to room temperature and flowed with O_2 gas for 1 h. After that, it was purged with He for 30 min to remove weakly adsorbed O_2. Then the temperature was increased from room temperature to 800 °C at the rate of 10 °C min^{-1} under the flow of He gas (30 mL min^{-1}).

2.3 Catalytic activity in C_2H_4 oxidation removal

The catalytic oxidation of ethylene was performed in a fixed-bed reactor with continuous flow under atmospheric pressure. 100 mg catalyst was placed in a quartz tube reactor. Typically, the as-synthesized MnO_2 and Pt/MnO_2 catalysts were pretreated with air at 373 K for 1 h. The typical composition of reactant gas was 20 ppm C_2H_4, 21 vol% O_2, and balance N_2. The hourly space velocity (GHSV) was 60 000 mL g^{-1} h^{-1}. The ethylene concentrations were analyzed by an on-line GC 2060 gas

chromatograph equipped with Flame Ionization Detector (FID), and the ethylene removal efficiency was calculated by the following formula:

$$\text{Removal efficiency} = (C_{\text{inlet}} - C_{\text{outlet}})/C_{\text{inlet}} \times 100\% \quad (1)$$

in which C_{inlet} and C_{outlet} are the C_2H_4 concentrations in the inlet and outlet gases, respectively.

3 Results and discussion

Fig. 1 shows the X-ray diffraction (XRD) patterns of the MnO_2 samples obtained by the facile redox reaction approach between $KMnO_4$ and MES at room temperature. All of the materials exhibit diffraction peaks at 12.5°, 25°, 36.5° and 65.5°, which are in good agreement with the (001), (002), (−111) and (−321) crystal planes of δ-MnO_2 (JCPDS 80-1098). In the case of Pt/MnO_2-48 h catalyst, the loading of Pt has not changed the crystal form of MnO_2 and no reflections belonging to Pt can be observed, indicating that Pt NPs are small enough and finely dispersed on MnO_2 matrix.[27] Notably, the intensities of the (001) and (002) reflections of MnO_2 remarkably decreases after Pt loading, suggesting that the Pt incorporation may have deteriorated the layered structure of δ-MnO_2 or exfoliated δ-MnO_2 into discrete nanosheets to a large extent.

The morphologies of MnO_2-48 h and Pt/MnO_2-48 h were characterized by Field Emission Scanning Electron Microscopy (FESEM) and Transmission Electron Microscopy (TEM). As can be seen from Fig. 2A, the obtained MnO_2 presents sheet-like morphology and all nanosheets are curled or crumpled due to surface tension, similar to most 2D nanosheets such as graphene. Fig. 2B shows that the Pt NPs are well decorated on the MnO_2 sheets. The TEM, high resolution TEM (HRTEM), high angle annular dark-field (HAADF) TEM images and EDS spectra of the as-prepared MnO_2-48 h and Pt/MnO_2-48 h samples are given in Fig. 3 and 4. As can be seen in Fig. 3A, the obtained MnO_2-48 h nanosheets are about 10 nm in thickness and up to hundreds of nanometers in their in-planar dimension, implying that MnO_2 with 2D layered structure has been successfully prepared through the simple redox reaction between $KMnO_4$ and MES without the complicated "up-bottom" process.[9] Furthermore, the EDS spectroscopy (Fig. 3B) shows that the obtained MnO_2 is composed of Mn, O and a small amount of K. Fig. 3C and D are the HRTEM images of MnO_2-48 h, which clearly demonstrates a *d*-spacing of 0.7 nm, corresponding to the interlayer distance of (001) facet of 2D layered structure δ-MnO_2. In addition, we can see that the as-synthesized MnO_2 nanosheets are polycrystallized and the crystallite size is around several nanometers (Fig. 3D). Clearly, two sets of lattice fringes can be observed, that can be ascribed to (002) and (−111) planes with *d*-spacing of 0.35 and 0.24 nm, respectively. After the loading of 2 wt% Pt, the nanosheet morphology of MnO_2 is retained, and the ~2 nm Pt NPs are highly dispersed on the MnO_2 nanosheets (Fig. 4A). EDS (Fig. 4B) spectrum of the selected area gives a Pt content of 1.99 wt%, which was further verified to be 1.90 wt% by inductively coupled plasma-optical emission spectroscopy (ICP-OES). As shown in the HRTEM image of Pt/MnO_2-48 h (Fig. 4C), a lattice spacing of *ca.* 0.23 nm is corresponding to the (111) lattice plane of Pt. The HAADF TEM image clearly reveals the uniform dispersion of Pt NPs on the planar surface of MnO_2 nanosheets.

N_2 adsorption–desorption isotherms were recorded (Fig. S1†) and the corresponding pore structure parameters are summarized in Table S1.† As shown in Fig. S1,† the specific surface area of MnO_2-48 h is the highest among these three catalysts. The specific surface area of Pt/MnO_2-48 h is lower than that of MnO_2-48 h due to the loading of Pt NPs.

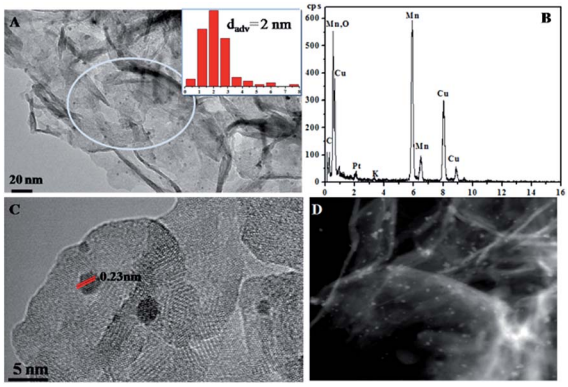

Fig. 4 The TEM image (A) (insert: the size distribution of Pt), EDS spectra (B), HRTEM image (C) and HADDF TEM image (D) of Pt/MnO_2-48 h.

The surface chemical composition, chemical state and surface-defect of the as-synthesized MnO_2 samples were analyzed by XPS. Fig. 5 shows the Mn 2p spectra and O 1s spectra of the as-synthesized MnO_2 samples. As can be seen from Fig. 5A, there are two bands centred at 642.2 eV and 653.6 eV, corresponding to the binding energy of Mn $2p_{3/2}$ and Mn $2p_{1/2}$, respectively. The Mn $2p_{3/2}$ can be deconvoluted into Mn^{2+}, Mn^{3+} and Mn^{4+} sub-bands at 641 eV, 642 eV and 644 eV,[28] respectively. The proportions of Mn^{2+}, Mn^{3+} and Mn^{4+} in the as-synthesized MnO_2 samples are listed in Table 1. It is clear that the amount of Mn^{2+} in all the samples is very low. The

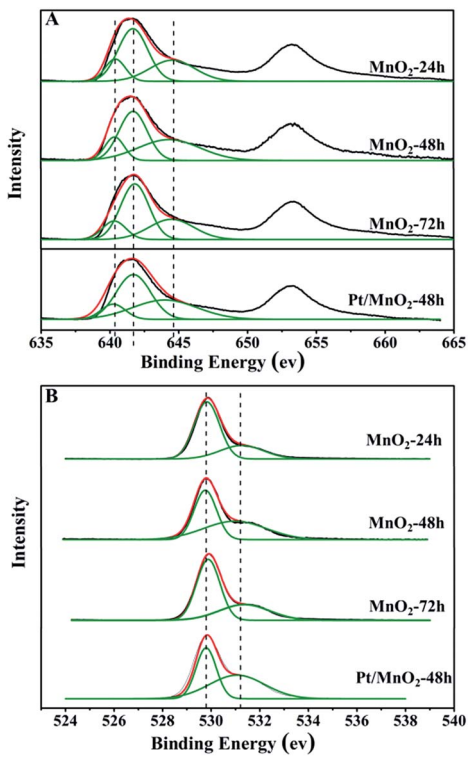

Fig. 5 XPS spectra of Mn 2p (A) and O 1s (B) of the as-synthesized MnO_2 and Pt/MnO_2-48 h catalysts.

Table 1 XPS of Mn 2p of the as-synthesized MnO_2 and Pt/MnO_2-48 h catalysts

Sample	Mn^{2+}	Mn^{3+}	Mn^{4+}	O_{ads}/O_{lat}
MnO_2-24 h	15.7%	52.6%	31.6%	0.33
MnO_2-48 h	15.1%	44.5%	40.4%	0.92
MnO_2-72 h	15.1%	54.3%	30.6%	0.53
Pt/MnO_2-48 h	12.1%	48.8%	39.1%	1.16

percentages of Mn^{4+} are 31.6%, 40.4% and 30.6% in MnO_2-24 h, MnO_2-48 h and MnO_2-72 h, respectively. The existence of Mn^{3+} will facilitate electron transfer between Mn^{3+}/Mn^{4+} and Mn^{4+}/Mn^{2+} pairs, which benefits the redox catalytic reaction.

The O 1s spectra are shown in Fig. 5B, and all the profiles can be fitted to two sub-bands, indicating two different kinds of oxygen species in the catalysts. The one of lower binding energy corresponds to lattice oxygen (O_{lat}), while the other at higher binding energy is for surface adsorbed oxygen (O_{ads}).[29] The surface O_{ads}/O_{lat} molar ratios are 0.33, 0.92 and 0.53 for MnO_2-24 h, MnO_2-48 h and MnO_2-72 h, respectively, as listed in Table 1. Notably, the percentage of surface adsorbed oxygen increased after the loading of Pt, which may be attributed to the larger amount of surface adsorbed oxygen on the highly dispersed Pt species. It has been reported that surface active oxygen species play an important role in oxidation reactions.[30] The adsorbed oxygen species result most likely from the presence of surface oxygen vacancies,[31] which favours the catalytic oxidation reaction.

The Pt 4f spectrum of Pt/MnO_2-48 h is shown in Fig. S2.† Two strong peaks represent the $4f_{7/2}$ and $4f_{5/2}$ electrons of Pt species, respectively.[32] This further confirms the successful deposition of Pt on MnO_2. The peak of $4f_{7/2}$ can be divided into two peaks located at 71 eV and 72 eV, which can be assigned to the $4f_{7/2}$ electrons of Pt^0 and Pt^{2+}, respectively. The existence of oxidized Pt (Pt^{2+}/Pt^0 ratio = 0.88) can be attributed to the formation of Pt–O and Pt–O–Mn bonds, corresponding to the increased amounts of O_{ads} and Mn^{3+} species in Pt/MnO_2-48 h after the Pt loading. This indicates the strong interaction between Pt and MnO_2, featuring the electron transfer from Pt^0 to adsorbed O_{ads} and surface O_{lat} in the MnO_2 support. The same phenomenon has also been found in Pt/Fe_3O_4 system.[33] This strong interaction between Pt and the MnO_2 support can be named as strong metal–support interaction (SMSI), as reported in many literatures,[34–36] and also recently summarized as a type of synergetic catalytic effects (type I of mutual activation of the two components).[20]

The reducibility of the synthesized manganese oxide catalysts, an important factor correlated with their redox activity, was investigated by H_2 temperature-programmed reduction (H_2-TPR). As shown in Fig. 6, there are two well-defined reduction peaks, corresponding to the stepwise reductions of MnO_2 and Pt/MnO_2-48 h in the temperature range of 300–500 °C. According to the previous reports, the first reduction peak centred at 350–400 °C is attributed to the reduction of MnO_2 to Mn_2O_3, and the second one centred at 450–500 °C is assigned to the reduction of Mn_2O_3 to MnO.[37,38] The complete reduction of

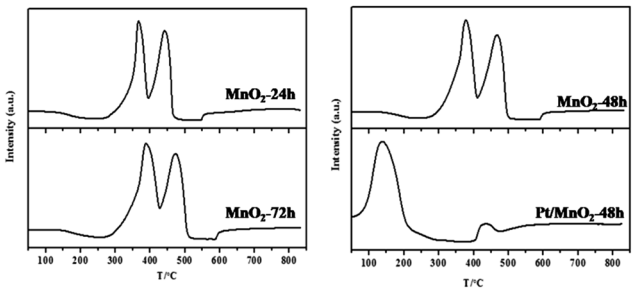

Fig. 6 H_2-TPR profiles of the as-synthesized MnO_2 and Pt/MnO_2-48 h.

MnO to metallic Mn did not happen in the reduction process of these samples. From the H_2-TPR profiles of the synthesized MnO_2, one can see that the reducibility of the MnO_2 follows the order of MnO_2-48 h ~ MnO_2-24 h > MnO_2-72 h. Compared with the TPR behaviour of MnO_2, the addition of Pt has dramatically altered the reduction feature of MnO_2. The Pt/MnO_2-48 h catalyst shows one intensive reduction peak at 137 °C. It has been reported that PtO_x species can be reduced below 250 °C despite the stoichiometry of Pt^{4+}/Pt^{2+} and the interaction between PtO_x and support.[39] Therefore, the peak at 137 °C could be attributed to the reduction of PtO to Pt. However, it should be noted that the H_2 consumption (5284 μmol g^{-1}) during the TPR of Pt/MnO_2-48 h was much higher than that necessary for the reduction of PtO (<102 μmol g^{-1}), indicating the low temperature reduction of a large part of MnO_2 support due to the strong SMSI between Pt and MnO_2. This is also in correspondence to the remarkably reduced band intensity (hydrogen consumption) of Pt/MnO_2-48 h beyond 400 °C. This phenomenon is related to the activation of H_2 on the initially reduced Pt and the spillover of the activated hydrogen to MnO_2, which largely facilitates the reduction of MnO_2.[40,41]

The O_2 temperature programmed desorption (O_2-TPD) tests were performed to further investigate the adsorbed oxygen species as well as their mobility in the synthesized MnO_2 and Pt/MnO_2-48 h (Fig. 7). Generally, the adsorbed oxygen will be desorbed according to the following sequence:[42] $O_{2(ad)} \rightarrow O^{2-}_{(ad)} \rightarrow O^{-}_{(ad)} \rightarrow O^{2-}_{(lat)}$. As can be seen from Fig. 7, almost all of the O_2-TPD profiles of these samples show three peaks. The first peak at about 240 °C can be assigned to the desorption of chemically adsorbed $O^{2-}_{(ad)}$ since the physically adsorbed $O_{2(ad)}$ is usually desorbed at around 50 °C.[43] The second peak at about 360 °C is ascribed to desorption of chemically adsorbed $O^{-}_{(ad)}$. The last desorption peak at about 600 °C can be assigned to lattice $O^{2-}_{(lat)}$ desorption from MnO_2 support. All MnO_2 samples show the similar capacity in chemically adsorbing $O^{2-}_{(ad)}$ and $O^{2-}_{(lat)}$. Exceptionally, MnO_2-72 h exhibits no desorption peak of $O^{-}_{(ad)}$. Among the three MnO_2 catalysts, the desorption temperature of the $O^{2-}_{(lat)}$ in MnO_2-72 h is a little higher than that of the other two MnO_2 samples, indicating that the surface lattice oxygen is less mobile in MnO_2-72 h. In the case of Pt/MnO_2-48 h, however, the peak area between 100 °C to 400 °C is larger than that of MnO_2-48 h, suggesting the enhanced chemical adsorption of O_2 ($O^{2-}_{(ad)}$, especially $O^{-}_{(ad)}$). Notably, Pt/MnO_2-48 h adsorbs more oxygen atom $O^{-}_{(ad)}$, suggesting abundant $O^{-}_{(ad)}$ adsorbed on the catalyst. More importantly, the desorption temperature of lattice oxygen $O^{2-}_{(lat)}$ in Pt/MnO_2-48 h down-shifts substantially from 600 °C to 470 °C, indicating the dramatically enhanced mobility of lattice oxygen in Pt/MnO_2-48 h. The much elevated chemical-adsorption of O_2 as well as the excellent mobility of lattice oxygen in Pt/MnO_2-48 h will greatly favour the enhancement on catalytic oxidation activity.

The oxidation of ethylene was used to evaluate the catalytic activity of the as-synthesized catalysts, and the results are shown in Fig. 8. The complete conversion temperatures of C_2H_4 are at 150 °C, 130 °C and 170 °C on MnO_2-24 h, MnO_2-48 h and MnO_2-72 h, respectively. In particular, MnO_2-48 h shows the best performance in removing 20 ppm ethylene without Pt-loading. After loading 2 wt% Pt on MnO_2-48 h, the as-synthesized Pt/MnO_2-48 h catalyst shows markedly enhanced catalytic activity in ethylene oxidation. The complete conversion temperature of C_2H_4 decreases from 130 °C to 50 °C. More importantly, the complete ethylene removal has been maintained for at least 12 h (Fig. 8B).

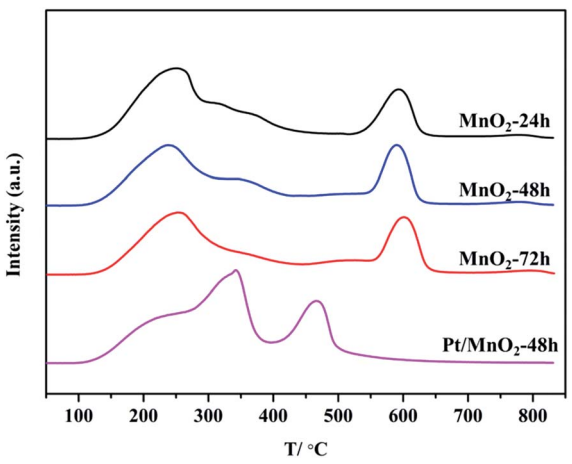

Fig. 7 O_2-TPD profiles of the as-synthesized MnO_2 and Pt/MnO_2-48 h.

3.1 Discussion on the structure–activity relation

As demonstrated above, the as-prepared MnO_2 materials are δ-MnO_2 built up with edge-shared MnO_6 octahedra with interlayer cations (K^+) to balance the charge, and the sample MnO_2-48 h features a 2D nanosheet morphology stacked with less than 5 layers of manganese oxide with a high surface area. Among all the MnO_2 samples, MnO_2-48 h processes the highest amount of surface adsorbed active oxygen species and the strongest reducibility. All these features make MnO_2-48 h the most active catalyst for C_2H_4 oxidation removal in the present study. A small amount of Pt incorporated on MnO_2-48 h remarkably enhanced the catalytic activity for ethylene oxidation. The high surface area of Pt/MnO_2-48 h favours the adsorption of HCHO. Moreover, based on the XPS and O_2-TPD results, the addition of Pt influences the valence distribution of Mn. The increased ratio of Mn^{3+}/Mn^{4+} would favour the formation of oxygen vacancies,

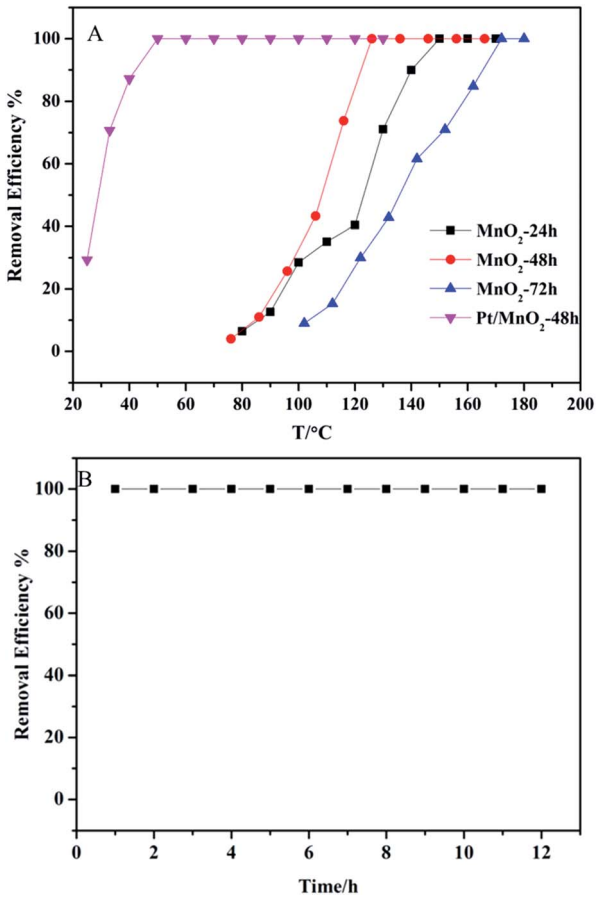

Fig. 8 (A) C_2H_4 removal efficiency of by the as-synthesized MnO_2 and Pt/MnO_2-48 h as functions of temperature; (B) C_2H_4 removal efficiency by Pt/MnO_2-48 h at 50 °C. Reaction condition: [C_2H_4] = 20 ppm, O_2 = 20.0 vol%, N_2 balance, GHSV = 60 000 mL g^{-1} h^{-1}.

which greatly benefits the adsorption and dissociation of oxygen molecules. Therefore, Pt/MnO_2-48 h had enhanced amount of surface adsorbed (activated) oxygen species. It is well-known that surface adsorbed oxygen species are highly active and therefore are responsible for the highly activity in catalytic oxidation of C_2H_4 at much lowered temperature.[44] As a result, the complete conversion temperature of C_2H_4 on Pt/MnO_2-48 h has reached down to 50 °C from 130 °C of MnO_2-48 h. Another important issue which should be mentioned is that the SMSI effect, which not only changes the electron structure of Pt and MnO_2 but also builds a fast channel for electron mobility and transfer between Pt and MnO_2 during the catalytic reaction process, endowing the composite catalyst a significantly synergetic catalysis effect. H_2-TPR results further proves the existence of the interaction between Pt and MnO_2, which leads to a much strengthened reducibility of Pt/MnO_2-48 h at a temperature down to 137 °C from ~400 °C of MnO_2-48 h, suggesting the surface mobility enhancement of lattice oxygen.

In the process of C_2H_4 catalytic oxidation, as shown in Fig. 9, C_2H_4 molecules would be adsorbed on the active surface of Pt.[45,46] The active oxygen species ($O^{2-}_{(ad)}$, especially $O^{-}_{(ad)}$) adsorbed on both Pt NPs and the surface oxygen vacancies of

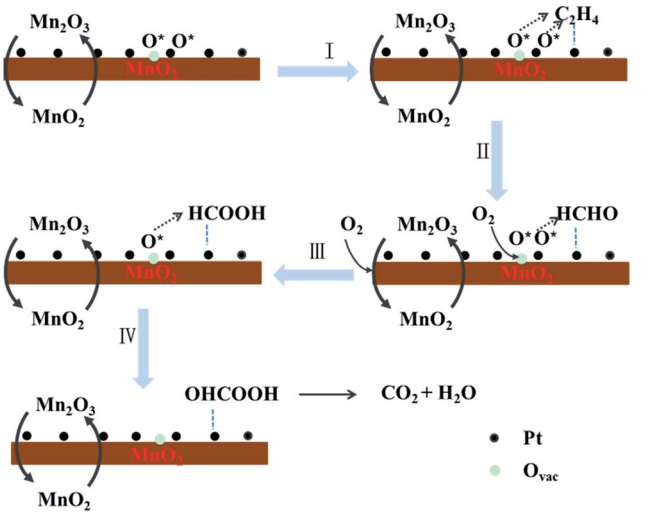

Fig. 9 The possible mechanism of C_2H_4 catalytic oxidation on Pt/MnO_2.

MnO_2 are primarily consumed in oxidizing C_2H_4 (Step I), producing HCHO according to the previous reports[24] (Step II). The oxygen vacancies on Pt/MnO_2 catalyst play a key role in the catalytic reaction, which enable the adsorption, dissociation, activation and migration of active oxygen species. The cycle of adsorption, activation and consumption of the active oxygen species on the oxygen vacancies of Pt/MnO_2 is accompanied by the redox cycling of Mn^{4+}/Mn^{3+} and Pt^{2+}/Pt^{0} [47] (Step II). The HCHO molecules will be further oxidized to HCOOH (Step III) and OHCOOH (Step IV) intermediates by the newly formed active oxygen species, and finally the OHCOOH completely decomposes into CO_2 and H_2O.

4 Conclusions

In summary, we have synthesized δ-MnO_2 nanosheets by a simple, environment-friendly and cost-effective approach *via* redox precipitation reaction between potassium permanganate and 2-(*N*-morpholino)ethane sulfonic acid (MES) at room temperature. The obtained MnO_2-48 h was able to catalyze the complete removal of low-concentration (20 ppm) ethylene at 130 °C. To further improve the catalytic ability of MnO_2, Pt nanoparticles (~2 nm in diameter) were highly dispersed on the MnO_2-48 h by colloidal deposition. The obtained catalyst Pt/MnO_2-48 h demonstrated markedly enhanced catalytic activity, which kept completely removing C_2H_4 (20 ppm) at 50 °C for at least 12 h. The high specific surface area and the enhanced amount of surface adsorbed oxygen species on Pt/MnO_2-48 h contribute to its high catalytic activity in ethylene oxidation. Furthermore, the strong metal–support interaction between Pt and MnO_2, is also proposed to play a role in elevating the redox catalytic activity of the Pt/MnO_2 composite catalyst.
