[rsc.li/nanoscale-advances](http://rsc.li/nanoscale-advances)A NiCo-MOF nanosheet array based electrocatalyst  
for the oxygen evolution reaction†Ponmuthuselvi Thangasamy,<sup>1</sup> Saravanakumar Shanmuganathan<sup>1</sup>  
and Viswanathan Subramanian<sup>1\*</sup>

Metal organic frameworks (MOFs) are excellent materials for energy storage and conversion. This report describes 2D metal–organic framework nanosheets as an electrocatalyst for the oxygen evolution reaction (OER) under alkaline conditions. An ultrathin nanosheet array of a NiCo-metal–organic framework was grown on nickel foam (NiCo-MOF/NF) by a one-step solvothermal method. The catalytic OER of the NiCo-MOF/NF electrode was analysed by electrochemical methods. The resulting NiCo-MOF/NF exhibited a high current density ( $50 \text{ mA cm}^{-2}$ ) with an overpotential of 270 mV, a Tafel slope of  $35.4 \text{ mV dec}^{-1}$  and a high turnover frequency (TOF) of  $0.68 \text{ s}^{-1}$  ( $\eta = 0.27 \text{ V}$ ) towards the OER. The excellent catalytic activity of the MOF towards the OER was due to the two-dimensional nanosheet array of NiCo-MOF with plentiful accessible molecular active sites and excellent mass transport properties. Faster electron transport was also achieved due to the synergetic effect of Co and Ni present on the MOF.

## Introduction

Metal–organic frameworks (MOFs) are crystalline porous materials constructed by the coordination of metal ions or clusters and organic linkers. In recent years, MOFs received tremendous attention in gas storage applications and active catalytic materials for energy-related applications due to their tunable porosity and readily accessible active sites.<sup>1</sup> Recent literature findings suggested that calcination at a high temperature may sacrifice MOF-derived electrocatalysts that possess intrinsic metal active sites, while hybridization with secondary supports, such as graphene, polyaniline and carbonaceous materials, may block their intrinsic micropores.<sup>2</sup> In addition, bulk MOFs have a limited micro and mesoporosity for an effective mass transport during electrocatalytic activity. 2D MOF nanosheets possess numerous accessible active sites, meso/macroporosity and a faster electron transfer, which are essential criteria to design high-performance electrocatalysts.<sup>3</sup> The merits of 2D-nanomaterials, such as plentiful active centres to improve the high catalytic activity and large surface area to volume ratio enable rapid mass transport and charge transfer.<sup>4</sup> Moreover, the strategy focusing on the water splitting reaction using MOFs as the electrode materials supported on secondary phases, such as self-supported materials on graphene,<sup>5</sup> black phosphorous,<sup>6</sup> Ni-foam<sup>7</sup> and Mxenes,<sup>8</sup> etc., is rapidly growing. Energy conversion and storage technologies (water splitting, metal–air batteries, and fuel cells) are totally

dependent on highly active electrocatalysts.<sup>9–11</sup> However, inherently very sluggish reaction kinetics have been observed due to the four-electron transfer steps and a large overpotential is required for the reaction. Precious noble metal-based electrocatalysts, such as  $\text{RuO}_2$  and  $\text{IrO}_2$ , are the benchmark catalysts for OER, but they hardly satisfy scale-up applications because of their scarcity and high cost.<sup>3</sup> Therefore, there is a critical need for cost-effective alternatives with efficient OER catalysts based on earth-abundant metals, such as transition metal oxides,<sup>12</sup> hydroxides<sup>13</sup> and carbonaceous materials.<sup>14</sup> Among these, nickel-based OER catalysts, including hydroxides,<sup>15</sup> sulfides<sup>16</sup> and phosphides,<sup>17</sup> have demonstrated better OER catalytic performances under alkaline conditions. In particular, bimetallic cobalt and Ni-based compounds display enhanced catalytic performances.<sup>18,19</sup> Recent investigation suggests metal–organic frameworks are highly suitable for OER applications. 2D nanosheet based electrodes received wide attention due to their nanostructure with a high catalytic activity<sup>20,21</sup> and emerged as excellent alternatives for OER applications. NiFe based MOF nanosheets directly supported on nickel foam acting as robust electrodes for an electrochemical oxygen evolution reaction was reported by Sun *et al.*<sup>21</sup> Duan *et al.* demonstrated that the electrocatalyst based on bimetallic MOF nanosheets have highly exposed active molecular metal sites with an enhanced catalytic performance for water splitting reactions.<sup>7</sup> Herein, we describe a simple method for the *in situ* growth of an ultrathin two-dimensional Ni–Co-MOF nanosheet array on nickel foam (NiCo-MOF/NF). The NiCo-MOF/NF electrode shows an OER with a small overpotential of 270 mV at a current density  $50 \text{ mA cm}^{-2}$  and is stable for 30 000 seconds without any noticeable activity decay.

## Results and discussion

FT-IR analyses were performed to investigate the participation of functional groups in the formation of MOFs. Fig. 1 shows two peaks at 1680 and 1424  $\text{cm}^{-1}$  which are characteristic peaks of the ligand  $\text{H}_2\text{BDC}$  (due to the asymmetric and symmetric ( $-\text{COO}^-$ ) stretching vibrations). The peaks at 1680 and 1424  $\text{cm}^{-1}$  are absent in the case of Ni-MOF and NiCo-MOF, thereby confirming that the ligands are coordinated with a metal centre. Further, NiCo-MOF (Fig. 1) shows peaks at 1579 and 1354  $\text{cm}^{-1}$ , corresponding to the asymmetric and symmetric ( $-\text{COO}^-$ ) stretching vibrations of the ligand coordinated to the metal centre. The peaks at 3424 and 1499  $\text{cm}^{-1}$  are ascribed to the stretching vibration of  $\text{OH}^-$  and *para*-aromatic CH groups, respectively. The appearance of peaks (Ni-O and Co-O) at 474, 603 and 699  $\text{cm}^{-1}$  corresponds to the formation of the metal-oxo bond between the (Ni or Co) atoms and the carboxylic group of the  $\text{H}_2\text{BDC}$  ligand. The above results reveal the formation of a metal centre ( $\text{Ni}^{2+}$ ,  $\text{Co}^{2+}$ ) coordinated with an organic linker ( $\text{BDC}^{2-}$ ). The FT-IR spectra of Ni-MOF and Co-MOF are shown in ESI Fig. 1.†

The Ni-foam substrate is highly flexible and mechanically robust with numerous macropores with the pore sizes of 200–500  $\mu\text{m}$ . The surface morphology of NiCo-MOF was characterized by field emission scanning electron microscopy (FE-SEM). The FE-SEM images of NiCo-MOF (Fig. 2a and b) confirmed the formation of ultrathin nanosheets uniformly arranged on Ni-foam. Ni-MOF/NF was synthesised in a similar solvothermal process except for  $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ . The figure (ESI Fig. 2)† displays the

Fig. 2 FE-SEM images of NiCo-MOF/NF at various scales: (a) 500  $\mu\text{m}$ , (b) 300  $\mu\text{m}$ , (c) 10  $\mu\text{m}$ , and (d) 5  $\mu\text{m}$ .

density of a 3D-parallellogram slice of Ni-MOF growing on Ni-foam, which obviously differs from that of 2D-NiCo-MOF/NF.

HR-TEM images of NiCo-MOF indicate the 2D nanosheet array formation with a well-defined ultrathin sheet-like structure (Fig. 3a). The 2D MOF nanosheets exhibit a crystalline structure, as evidenced by the clear lattice fringes (0.75 nm lattice space, Fig. 3b). The 2D-NiCoMOF nanosheet array formation was confirmed by AFM. The thickness of the NiCo-MOF sheet was found to be  $\sim 2\text{--}5$  nm (Fig. 3c) with only a few molecular nanolayers stacked.

XRD of Ni-MOF and Ni-Co-MOF nanosheets was carried out and the results are depicted in the Fig. 3. The XRD pattern of Ni-

Fig. 1 FT-IR spectra of NiCo-MOF, Ni-MOF and the BDC ligand.

Fig. 3 (a) and (b) HR-TEM images (scale bars: 100 nm and 5 nm, respectively), (c) an AFM image, and (d) the P-XRD pattern of the NiCo-MOF nanosheet array.

MOF revealed peaks at  $2\theta$  values of  $11.29^\circ$ ,  $11.72^\circ$ ,  $15.06^\circ$ ,  $23.29^\circ$ ,  $28.58^\circ$ , and  $34.51^\circ$ . These peaks are well-matched with crystalline data CCDC: 638866.<sup>22</sup> The XRD pattern of the NiCo-MOF exhibited peaks at  $2\theta$  values of  $15^\circ$ ,  $23.7^\circ$ ,  $28.9^\circ$  and  $51^\circ$  that belong to the (111), (220), (311) and (511) planes, respectively. The diffraction results for NiCo-MOF were verified with the reported JCPDS no: 73-1704 data.<sup>23</sup> A similar pattern was obtained for bimetallic NiCo-MOF. Co ion insertion altered the triclinic crystal structure of Ni-MOF to a face-centred cubic crystal structure. These results confirmed that the nickel and cobalt ions are involved in the MOF formation.

X-ray photoelectron spectroscopy (XPS) analysis was carried out to find the surface composition and the surface electronic states for NiCo-MOF and investigate the charge transfer processes in the valence state of the nickel and cobalt ions of NiCo-MOF, as well as synergetic effect of nickel and cobalt species (Fig. 4a).

The XPS spectrum of NiCo-MOF/NF shows the presence of C, O, Ni and Co elements. The high-resolution XPS (HR-XPS) spectrum of C 1s is deconvoluted into the three surface components corresponding to the benzene rings of the BDC ligand (285.6 eV), the carboxylate rings of the (O=C-O) groups of the organic ligand (288.8 eV), and -C-O (287.2 eV).<sup>21</sup> Fig. 4c is the XPS spectrum of O 1s fitted by two peaks at binding energies 532.9 and 534.3 eV, which can be attributed to the presence of oxygen atoms on the Ni and Co-O bonds and the carboxylate moiety of the organic ligand, respectively. HR-XPS of Ni 2p and Co 2p spectra both show  $2p_{1/2}$  and  $2p_{3/2}$  components due to

spin-orbit coupling. The high-resolution Ni 2p spectra of the NiCo-MOF/NF show characteristic peaks of the  $\text{Ni}^{2+}$  oxidation state. The binding energy of 857.4 eV ( $2p_{3/2}$ ) was assigned to the Ni-O corresponding to the MOF structure, while the binding energy peak around 875.5 eV ( $2p_{1/2}$ ) was assigned to Ni-OH.

The binding energy peaks around 862.6 ( $2p_{3/2}$ ) and 882.4 eV were ascribed to the satellite peak of Ni 2p. The high-resolution Co 2p spectrum of NiCo-MOF/NF (Fig. 4e) displays two peaks corresponding to Co  $2p_{3/2}$  and Co  $2p_{1/2}$  at 782.0 eV and 798.3 eV, respectively. The binding energy values of 804.4 eV and 787.9 eV were assigned to -Co-OH and the satellite peak of Co 2p. From the XPS data (Fig. 4a), the chemical composition of the NiCo-MOF material exhibited that carbon (43.78 at%), oxygen (45.42 at%), nickel (6.60 at%) and cobalt (4.19 at%) are present.

Fig. 5 shows that NiCo-MOF nanosheets have type IV nitrogen adsorption/desorption isotherms, which indicates that the nanosheets are rich in mesoporous. The prepared 2D-nanosheets showed the higher surface area of  $380 \text{ m}^2 \text{ g}^{-1}$  and the Brunauer-Emmett-Teller (BET) surface area shows mesoporosity and the average diameter of pore size is 12 nm. The high surface area and abundant mesoporous nature of NiCo-MOF nanosheets provide benefits for the access of the electrolyte with OER active sites.

The electrocatalytic performance of the NiCo-MOF/NF nanosheet array towards the oxygen evolution reaction was investigated using a standard three-electrode cell containing 1.0 M KOH. In prior OER experiments, all the prepared samples were subjected to cyclic voltammetry (10 cycles) at a sweep rate of  $50 \text{ mV s}^{-1}$  to initiate the pre-activation process. For comparison, electrochemical studies of the Ni-MOF/NF, Co-MOF/NF, BDC/NF, and Ni/Co-MOF/NF nanosheets, of Ni-MOF, Co-MOF, and Ni/Co-MOF synthesized by an *in situ* route and coated on the Ni-foam and of the benchmark catalyst  $\text{IrO}_2$  on Ni foam were performed under the same conditions. Fig. 6a shows the linear sweep voltammetric results (LSV) of the as-prepared above-mentioned catalysts. The Ni/Co-MOF/NF nanosheet array exhibited an overpotential of 270 mV at a current density  $50 \text{ mA cm}^{-2}$  which is extremely smaller than that of Ni-MOF/NF (380 mV), BDC/NF (395 mV), Ni/Co-MOF coated on the Ni-foam (370 mV, bulk), calcined NiCo-MOF (at 400 C for 4 h in  $\text{N}_2$  gas, 454 mV) and  $\text{IrO}_2$  (320 mV). The low overpotential of the NiCo-MOF/NF nanosheet array confirms its excellent OER activity due to the results from the flexible

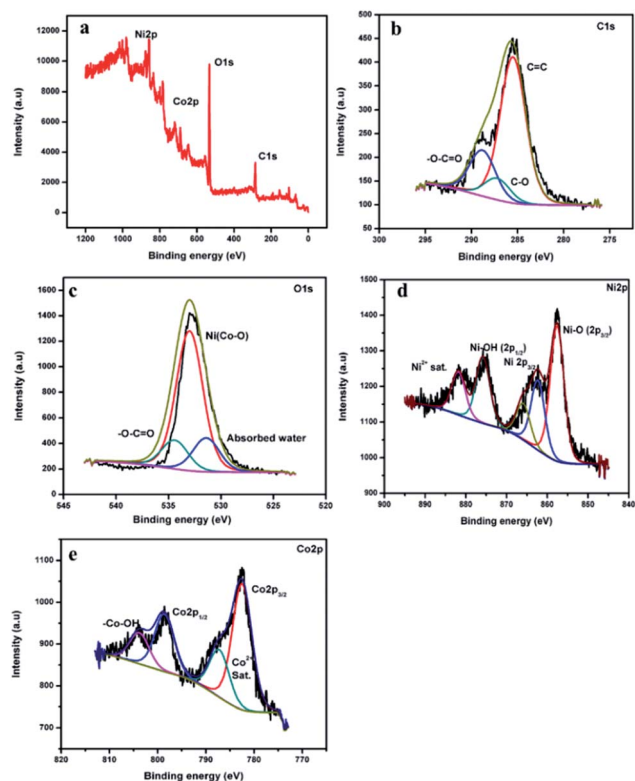

Fig. 4 (a) XPS survey spectra of NiCo-MOF/NF, and (b–e) C 1s, O 1s, Ni 2p and Co 2p high resolution spectra, respectively.

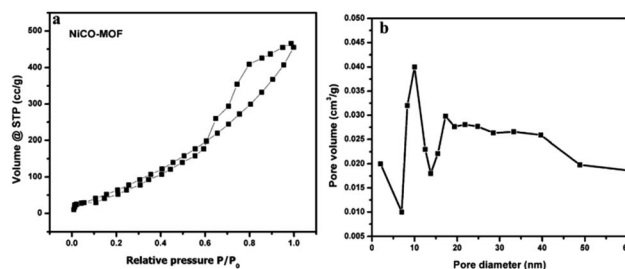

Fig. 5 (a)  $\text{N}_2$  adsorption-desorption isotherms of the NiCo-MOF nanosheet array, and (b) the corresponding pore size determination of the NiCo-MOF nanosheet array.

electron transfer across the fine sheet arrangement with sheets that are vertically arranged on the nickel foam.

Proposed mechanisms for the NiCo-MOF catalysed OER activity:

Steps (1) and (2) may involve reversible process. Step (3) is fast, irreversible and also the rate determining step of the entire process. Presumably, NiCo-MOF is faster because of the reaction kinetics relating to step (3). In the event of anodic OER,  $\text{LCo}(\text{NiO}_4)$  inside MOF was oxidised into  $\text{L}(\text{Co})\text{NiOOH}$  species which promotes the oxidation of  $\text{OH}^-$  into  $\text{O}_2$ .<sup>9</sup> The outstanding electrocatalytic activity of the NiCo-MOF nanosheet is also evidenced through the turnover frequency (TOF) of  $0.68 \text{ s}^{-1}$ , with the current density at a low overpotential of 270 mV, which is twice that of Ni-MOF ( $0.35 \text{ s}^{-1}$ , with the current density at a low overpotential of 380 mV) and  $\text{IrO}_2/\text{NF}$  ( $0.58 \text{ s}^{-1}$ , with the current density at an overpotential of 320 mV).

The NiCo-MOF/NF nanosheet array exhibited a better catalytic activity than that of other electrodes towards OER with a Tafel slope of  $35.4 \text{ mV dec}^{-1}$  (Fig. 6). This slope value is much lower than those of other compositions samples, such as NiCo-MOF bulk ( $57 \text{ mV dec}^{-1}$ ), Ni-MOF/NF ( $64.4 \text{ mV dec}^{-1}$ ), BDC/NF ( $71 \text{ mV dec}^{-1}$ ) and  $\text{IrO}_2$  ( $43.5 \text{ mV dec}^{-1}$ ). These results confirm that the NiCo-MOF/NF nanosheet array exhibited an excellent catalytic activity compared to other existing catalysts owing to the intrinsically highly active sites and hierarchical porous structure, which permit a high surface area and easy to transport gaseous products.

Another possible reason for the enhanced electrocatalytic activity after the addition of Co, the electrochemically active surface area (ECSA), was evaluated and is proportional to the double layer capacitances ( $C_{dl}$ ). Different scan rates of cyclic voltammograms were performed in the potential range of 0.9 to 1.2 V (vs. the reversible hydrogen electrode (RHE)) without a redox process in various electrodes, such as NiCo-MOF/NF, Ni-MOF/NF, Co-MOF/NF and bulk NiCo-MOF. The  $C_{dl}$  was

Fig. 7 Electrochemically active surface area (ECSA) evaluation.

calculated as  $i = \nu C_{dl}$ , where  $i$  is the double layer current measured by cyclic voltammograms at different scan rates from 10 mV to 100 mV.<sup>24</sup> From the results, the best electrocatalytic OER activity of NiCo-MOF/NF could be related to a major ECSA, which is beneficial for the contact area of the electrode and electrolyte (Fig. 7).

Electrochemical impedance spectroscopy (EIS) consists of two frequency regions: a semicircle at a higher frequency and linear at low frequencies. The semicircle corresponds to faradaic resistance and is caused by interfacial charge transport in the electrode interface. EIS of the NiCo-MOF/NF, Ni-MOF/NF, Co-MOF/NF, BDC/NF, and Ni-foam were measured in a solution of 1 M KOH. As shown in Fig. 8, the semicircle diameter of the NiCo-MOF/NF nanosheet array is much smaller than those of other catalysts such as Ni-MOF/NF, Co-MOF/NF, BDC/NF, and Ni-foam, which demonstrates that the NiCo-MOF/NF electrode has a smaller electronic resistance other than the other electrodes. These results support that the incorporation of Co atoms into the Ni-MOF/NF structure can enhance the electron transport properties of the electrode-electrolyte interface, which enhances the electrocatalytic process.

**Fig. 9** (a) Polarization curves of NiCo-MOF/NF before and after 3000 cycles in 1.0 M KOH. (b) The chronoamperometric curve of NiCo-MOF/NF at 1.5 V.

Literature results were compared with those for NiCo-MOF/NF developed in this work and are listed in Table 1. The NiCo-MOF/NF nanosheet array shows a lower over potential, lower Tafel slope and higher stability than those reported in the literature.

The major highlight of this work is that the NiCo-MOF nanosheets (~2–5 nm Fig. 3) possess highly active sites on

their surface which could be enhanced by catalytic activity. NiCo-MOF was directly grown on Ni-foam, which is a combination of macropores, mesoporous and intrinsic microporosity. The macropores of nickel foam facilitated the mass transport of electrolytes and dissipated the gaseous products. The mesopores of the NiCo-MOF nanosheet array provide plentiful accessible active sites and easy ion diffusion pathways (inward OH<sup>-</sup> ion and outward O<sub>2</sub> bubbles).

XPS analysis investigated the charge transfer processes in the valence state of nickel and cobalt ions of NiCo-MOF. XPS confirmed that the valence electronic configuration of Co<sup>2+</sup> is 3d<sup>7</sup> with a high spin state and therefore Co<sup>2+</sup> has unpaired electrons in a pi-symmetry (t<sub>2g</sub>). The d-orbital of Co<sup>2+</sup> interacts with the bridging O through  $\pi$ -donation. Ni<sup>2+</sup> ions have more electrons in  $\pi$ -symmetry (t<sub>2g</sub>) d-orbitals relative to those in Co<sup>2+</sup>. This property will increase the electron-donating ability of the  $\pi$ -symmetry lone pairs of the bridging oxygen atoms by repulsion. After hybridization, the charge is transferred from cobalt to nickel through organic ligands. These lattices offer a more stable environment for metal ions. A supplementary reason

**Scheme 1** A schematic illustration of the synthesis of the NiCo-MOF/NF nanosheet array.

explains the increase in the  $\text{Ni}^{2+/3+}$  redox potential when  $\text{Co}^{2+}$  ions are incorporated into Ni-MOF (ESI Fig. 5†). After the incorporation of cobalt ions in the MOF structure they enhance the OER performance due to the synergistic coupling between Ni and Co. Finally, the binder-free NiCo-MOF/NF nanosheet array electrode minimises the resistance of the catalyst and overpotential due to the interaction of the catalysts and conductive NF.

### Stability and durability

The stability of the NiCo-MOF/NF nanosheet array was evaluated by continuous CV for 3000 cycles at a scan rate of  $50 \text{ mV s}^{-1}$ . After 3000 cycles, no significant change ( $\eta = 50 \text{ mV}$  increase at a current density of  $50 \text{ mA cm}^{-2}$ ) in the current density was noticed at the NiCo-MOF/NF nanosheet array electrode (Fig. 9a). The long-term durability of the NiCo-MOF/NF nanosheet array was also tested by the chronoamperometric test at  $1.5 \text{ V}$  for  $30\,000 \text{ s}$  (Fig. 9b). These results indicated that the developed electrode is stable and suitable for OER. Additionally, the morphology and crystal structure of the NiCo-MOF nanosheets are completely maintained after the chronoamperometric measurements (ESI Fig. 3 and 4†), proving the excellent stability.

## Conclusions

In summary, this work demonstrates a simple one step strategy to synthesise a 2D NiCo-MOF nanosheet array on the surface of Ni-foam. The structural morphology was examined *via* FT-IR, PXRD, FE-SEM, HR-TEM, BET, and XPS. The electrocatalytic properties of the NiCo-MOF/NF nanosheet array towards the OER under alkaline conditions were tested. The NiCo-MOF/NF nanosheet array electrode exhibited a higher OER performance, with a current density of  $50 \text{ mA cm}^{-2}$ , a low overpotential of  $270 \text{ mV}$  and a Tafel slope of  $35.4 \text{ mV dec}^{-1}$ . The OER electrocatalytic activity observed in this work is due to the high accessible surface area and the synergetic effect between Co and Ni. In addition, excellent electrode stability is observed due to the *in situ* growth of an ultrathin film MOF on the nickel foam. These results revealed that the MOF nanosheet array is an excellent electrocatalyst for the OER under alkaline conditions.

## Experimental details

### Synthesis of the NiCo-MOF/NF electrode

The bimetallic Ni-Co-MOF material was synthesised by mixing solutions of  $\text{Ni}^{2+}$ ,  $\text{Co}^{2+}$  salts together with benzene 1,4-dicarboxylic acid (BDC) *via* a one-step solvothermal method. Briefly, a piece of the nickel foam ( $1 \text{ cm} \times 1 \text{ cm}$ ) was washed successively with dilute HCl solution and acetone in an ultrasonic bath for 20 minutes respectively to remove the surface oxide layer and organic residue. After cleaning with Millipore water, it was then dried at  $60^\circ\text{C}$  for 30 minutes. Nickel chloride ( $\text{NiCl}_2 \cdot \text{H}_2\text{O}$ ,  $7 \text{ mg}$ ), cobaltous chloride ( $\text{CoCl}_2$ ,  $3 \text{ mg}$ ) and 1,4-benzene dicarboxylic acid (BDC,  $10 \text{ mg}$ ) were dissolved in a  $10 \text{ mL}$  mixture solution of DMF/ethanol/water ( $5 : 3 : 2$ ). After

continuous ultrasonication for 30 minutes to obtain a clear solution, the mixture solution was transferred into a  $25 \text{ mL}$  Teflon-lined stainless steel vessel and the dried NF was placed in an autoclave. Then, the autoclave was sealed and maintained at  $120^\circ\text{C}$  for  $12 \text{ h}$  in an oven. After attaining room temperature, the nickel foam was taken out from the Teflon container and ultra-sonicated for  $5 \text{ min}$  and then rinsed with deionised (DI) water to get the 2D NiCo-MOF nanosheet array (Scheme 1).

### Synthesis of Ni-MOF/NF and Co-MOF/NF electrodes

The Ni-MOF/NF and Co-MOF/NF materials were prepared with the same protocol as used for  $\text{CoCl}_2$  or  $\text{NiCl}_2 \cdot \text{H}_2\text{O}$ .

### Synthesis of the BDC/NF electrode

The BDC/NF material was synthesised by following the same protocol but without  $\text{CoCl}_2$  and  $\text{NiCl}_2 \cdot \text{H}_2\text{O}$ .

### Instrumentation

The phases of the materials were analysed by Powder X-ray diffraction patterns (PXRD, X'PERT-PRO model with  $\text{Cu K}\alpha$  radiation sources ( $\lambda = 0.15406$ )). The morphologies of the samples were examined on a field emission scanning electron microscope (FE-SEM, FEI-quanta FEG 250). High-resolution transmission electron microscopy (HR-TEM) analyses were performed by a transmission electron microscope (JEOL/JEM 2100). X-ray photoelectron spectroscopy (XPS, k-alpha surface analysis, Thermo Fisher scientific, UK) was used to characterise the chemical composition of the electrode material. The XPS analysis was carried out at the binding energy of  $0$  to  $1350 \text{ eV}$ . A Fourier-transform infrared spectrometer (FT-IR, SHIMADZU, using KBr pellets) was used to find the functional groups. BET analysis was performed to analyse the surface area and porosity using  $\text{N}_2$  adsorption-desorption isotherms (Micromeritics Tristar 3000 instrument at  $77 \text{ K}$ ).

Electrochemical measurements were carried out using an AUTOLAB PGSTAT32 electrochemical workstation in a three-electrode system in  $1.0 \text{ M KOH}$ . The NiCo-MOF/NF electrode was utilised as a working electrode, platinum rod as a counter electrode, and  $\text{Ag/AgCl/KCl}$  ( $3.0 \text{ M}$ ) as a reference electrode. All the measured potentials were converted into a reversible hydrogen electrode (RHE) according to eqn (5):

$$E_{(\text{RHE})} = E_{\text{Ag/AgCl}} + 0.197 \text{ V} + 0.059 \text{ pH}. \quad (5)$$

Linear sweep voltammetry (LSV) and cyclic voltammetry (CV) were recorded by sweeping the potential from  $-0.2$  to  $0.8$  (vs.  $\text{Ag/AgCl}$ ) at a scan rate of  $10 \text{ mV s}^{-1}$ . Electrochemical impedance spectroscopy (EIS) was recorded in the frequency range from  $10^5 \text{ Hz}$  to  $0.1 \text{ Hz}$ . All the solutions were prepared using Millipore  $18 \text{ MOhm}$  water. All the electrochemical experiments were done under a high-purity  $\text{N}_2$  blanket.

### Calculations

The turnover frequency (TOF) was calculated from eqn (6):

$$\text{TOF} = J \times A/4 \times F \times m \quad (6)$$

Here,  $J$  is the current density ( $\text{A cm}^{-2}$ ) at an overpotential of 0.27 V. 'A' and 'm' are the area of the electrode and the number of moles of the active materials on the electrode, respectively, and 'F' is the Faraday constant ( $96\,485\text{ C mol}^{-1}$ ).

The authors thank Dr Subbiah Alwarappan, CECRI, India, for his helpful discussion. We are grateful to the Department of Science and Technology for providing financial assistance from a DST-PURSE Phase II/10815/2017 fellowship. Dr Saravanakumar is thankful to SERB, New Delhi for generous research funding through the Young Scientist Scheme (Sb/FT/CS-83/2014). The authors gratefully acknowledge financial support given by RUSA-Phase 2.0 [Lr.No.F.24-51/2014 U, Policy (TN Multi-Gen), Department of Education, MHRD, Government of India, dated 9.10.2018].
