Accepted Manuscript

This article can be cited before page numbers have been issued, to do this please use: C. Polesca, H. Passos, P. Nakasu, J. A. P. Coutinho, M. G. Freire and J. P. Hallett, *RSC Sustain.*, 2024, DOI: 10.1039/D4SU00179F.

This is an Accepted Manuscript, which has been through the Royal Society of Chemistry peer review process and has been accepted for publication.

Accepted Manuscripts are published online shortly after acceptance, before technical editing, formatting and proof reading. Using this free service, authors can make their results available to the community, in citable form, before we publish the edited article. We will replace this Accepted Manuscript with the edited and formatted Advance Article as soon as it is available.

You can find more information about Accepted Manuscripts in the [Information for Authors](#).

Please note that technical editing may introduce minor changes to the text and/or graphics, which may alter content. The journal's standard [Terms & Conditions](#) and the [Ethical guidelines](#) still apply. In no event shall the Royal Society of Chemistry be held responsible for any errors or omissions in this Accepted Manuscript or any consequences arising from the use of any information it contains.

Sustainability Spotlight statement

This article presents a novel approach to the smart design of circular biocomposites by combining low-cost and abundant biopolymers, producing keratin-based films either pure or blended with cellulose and α -chitin, each of which is derived from waste. A bio-based solvent was used for biopolymer dissolution, enabling a sustainable and cost-effective approach. As an exemplar application, the films were used as adsorbents for contaminated water, achieving higher adsorption capacity than common adsorbents reported in the literature. This marks the first reported results on developing keratin-chitin films, offering a more sustainable alternative to chitosan. This work aligns with the UN Sustainable Development Goals: decent work, economic growth (SDG 8), and responsible consumption and production (SDG 12).

Poultry is a widely consumed meat worldwide; however, its industrial processing generates a significant amount of feather waste. Since the major component of chicken feathers is keratin (90 wt. %), this study focused on using acetate-based ionic liquids (ILs) to fully dissolve chicken feathers and recover keratin, using a sustainable and cost-effective approach, ultimately allowing waste valorisation. The recovered keratin was processed into films, either pure or blended with cellulose and α -chitin, aiming to develop a structural polymer biocomposite with improved mechanical properties. Experimental parameters were evaluated using different blend ratios, altering the pH, and adding glycerol as a plasticiser. Physico-chemical analysis revealed that all films exhibited hydrophilic behaviour and are stable up to 160 °C. Furthermore, the tensile strength of the keratin-based films significantly increased by adding chitin (achieving up to 66 MPa). Considering the growing significance of biopolymer-based films in wastewater treatment applications, the keratin-based films were evaluated as adsorbents for dye removal. Reactive Blue 4 (RB4) was used as a model dye, and the adsorption kinetics and isotherms were investigated. Between the studied films, the maximum adsorption capacity (55.7 mg·g⁻¹) was obtained for the keratin film, emphasising the potential of this biomaterial in wastewater treatment.

1 Introduction

The global meat industry produces around 15 million tons of chicken feather waste annually¹, posing challenges such as negative impacts on the land composition and environmental pollution (affecting nitrogen and phosphorous cycles), and a high cost for disposal². Chicken feathers contain nearly 90 wt. % keratin, a valuable protein source for sustainable and environmentally friendly resource development^{1,3}. However, keratin recovery is challenging, mainly because of the inter- and intramolecular disulphide bonds between sulphur-containing amino acid residues and extensive cross-linking, which are resistant to water, weak acids, and organic solvents^{2,4,5}. Ionic liquids (ILs) have been investigated to overcome such issues due to their excellent dissolution capability and high efficiency for protein recovery^{6–11}. ILs are salts formed by a large organic cation and an organic or inorganic anion, with lower melting temperatures than inorganic salts^{5,8,12}. Recently, we demonstrated the ability of acetate-based ILs for feather

dissolution, which is due to the anion's high hydrogen-bonding acceptor ability, further providing an efficient keratin recovery (up to 93 wt. %) and a more sustainable pathway for producing keratin films^{11,13}. The IL recovery (over at least four cycles) was successfully achieved, and a techno-economic assessment of the process was performed, demonstrating the potential for a cost-effective and environmentally friendly process¹³. Keratin applications involve several areas, including use in the biomedical field and as an adsorbent for water treatment/remediation^{14–16}. Water contamination is a global concern, with the textile industry generating more than 7 million tons of toxic, carcinogenic, and nonbiodegradable dyes annually¹⁵. These substances pose threats to human health and aquatic life^{3,16}. In the textile industry, reactive dyes (e.g. reactive blue 4, RB4) are widely used (around 700,000 tons of dyes are annually produced) and present acute toxicity (LD50 oral 8.98 mg·kg⁻¹)^{17,18}. The environmental impact of RB4 assessed by EPI Suite™ confirms its slow environmental degradation (150 days in water and soil and 600 days in sediment)¹⁹, highlighting the urgency to develop strategies to mitigate this concern.

Several water treatment methods have been investigated to address this issue, including chemical oxidation, electrochemical oxidation, ion exchange, and adsorption¹⁴. The typical water treatment technologies are energy-intensive and involve unsustainable synthetic materials. However, adsorption, particularly using biomaterials like keratin^{20–22}, has shown promising results as a clean and effective alternative method³. Keratin-based adsorbents are attractive because their functional groups (e.g. hydrophobic and hydrophilic amino

1 acids and carboxyl groups, such as $-NH_2$, $-COOH$, $-SH$, and $-OH$ 49
 2 act as effective adsorption sites to a broad range of aqueous 50
 3 contaminants, accentuating their performance. Keratin is a 51
 4 fibrous protein with a high surface area, enhancing its 52
 5 adsorption capacity^{14,23,24}. Moreover, it is an available 53
 6 biodegradable, non-toxic, low-cost biomaterial^{3,15,21}. While 54
 7 previous studies have demonstrated the feasibility of keratin 55
 8 based adsorbents^{25,26}, challenges remain in cost-effectiveness 56
 9 processes for its recovery and poor tensile strength of the 57
 10 produced films²⁷. To overcome some of these challenges, we 58
 11 propose the use of the previously developed cost-effective 59
 12 process for keratin recovery using ILs^{11,13}, focusing now on 60
 13 preparing keratin-based films with improved mechanical 61
 14 properties by creating blends with cellulose and chitin for water 62
 15 purification. The idea is to employ the smart design of 63
 16 biocomposites by combining different types of low-cost and 64
 17 relatively abundant biopolymers. To blend with keratin, two 65
 18 structural biopolymers were chosen to enhance the mechanical 66
 19 properties of the films without compromising their 67
 20 biodegradability^{24,28}: cellulose — an abundant biopolymer with 68
 21 good mechanical and thermal properties^{29,30} — and chitin — 69
 22 acetylated polysaccharide with outstanding mechanical 70
 23 properties, such as high strength and high toughness^{31,32}. The 71
 24 strong interaction between keratin and these polymers 72
 25 attributed to their strong hydrogen bonding network between 73
 26 their functional groups (CH_3 , $CONH$, NH_2 and OH)³³. 74
 27 The processing conditions for the preparation of keratin films 75
 28 (e.g. keratin concentration, pH, addition of glycerol as a 76
 29 plasticiser, effect of three acetate-based ILs, and the 77
 30 biopolymer ratio) were varied by means of the design 78
 31 experiments to evaluate their influence on the film properties 79
 32 All keratin-based films were characterised using 80
 33 physicochemical, mechanical, and morphological analyses, and 81
 34 their potential as adsorbent materials for dye removal was 82
 35 explored using RB4. The adsorption kinetics and isotherms were 83
 36 examined. In summary, this work focuses on developing 84
 37 keratin-based films with adequate properties for application 85
 38 wastewater treatment, while contributing to waste 86
 39 valorisation. 87

40 Materials and Methods

41 Materials

42 Chicken feathers were collected from Campoaves Company 87
 43 Oliveira de Frades, Portugal, and pre-treated before dissolution 88
 44 as reported in the literature¹¹. The ILs used, viz. 1-butyl 89
 45 methylimidazolium acetate ($[C_4C_1im][C_1CO_2]$) (>95 wt. % pure) 90
 46 and 1-ethyl-3-methylimidazolium acetate $[C_2C_1im][C_1CO_2]$ (>95 91
 47 wt. % pure) were purchased from Sigma-Aldrich. Ethanol (99.8 92
 48 wt. % pure), acetic acid (>99.7 wt. % pure), sodium hydroxide 93

(NaOH), and ethylene glycol were acquired from Fisher 94
 Scientific. Glycerol (>99 wt. % pure) was purchased from Acros 95
 Organics. Cholinium bicarbonate, cellulose highly purified, 96
 hydrochloric acid (HCl) (>37 wt. % pure) and RB4 (35 wt. % pure) 97
 were obtained from Sigma-Aldrich. α -chitin from shrimp was 98
 purchased from Apollo Scientific. Cholinium acetate 99
 ($[N_{111(20H)}][C_1CO_2]$) was synthesised as previously described by 100
 Muhammad et al.³⁴. Briefly, acetic acid was added dropwise to 1
 cold cholinium bicarbonate in a round-bottom flask and stirred 2
 overnight. The moisture content in the synthesised IL was 3
 removed using a rotatory evaporator consisting of rotavapor R- 4
 10, heating bath B-491, vacuum pump V-700 and vacuum 5
 controller V-850 (all from Buchi, Switzerland). The water 6
 content was determined using a V20 Volumetric Karl-Fischer 7
 titrator (Mettler Toledo). The purity of the IL, confirmed by 8
 proton nuclear magnetic resonance (1H -NMR), is available in the 9
 Supporting Information (Figure S1).

Chicken feather dissolution and keratin recovery

Chicken feathers were dissolved, as previously reported by our 1
 research group^{11,13}. Different aqueous solutions of $[C_4C_1im][C_1CO_2]$, 2
 $[C_2C_1im][C_1CO_2]$, and $[N_{111(20H)}][C_1CO_2]$ (80 wt. % IL + 20 wt. % water) 3
 were used for feather dissolution at 100 °C for 4 h in a solid:liquid 4
 (chicken feather:solvent) ratio of 1:20 w/w. After dissolution, keratin 5
 was recovered by adding water as a coagulant solvent in a 6
 solution:coagulant ratio of 1:2 w/w at 5 °C for 1 h. Then, the solution 7
 was centrifuged for 20 min at 4000 rpm in a refrigerator centrifuge 8
 machine (VWR® Mega Star 4.0), promoting the separation of the 9
 precipitated keratin. The protein was then washed with DI water to 10
 remove any residual IL and centrifuged at the previously described 11
 conditions. The wet keratin was used for film processing. Keratin 12
 recovery yield of up to 93 wt. % was obtained, in agreement with 13
 previous assays^{11,13}.

Keratin-based film processing

Wet keratin recovered by $[C_4C_1im][C_1CO_2]$ was used to investigate 1
 the film processing conditions: protein concentration (on distilled 2
 water), solution pH (adjusted with NaOH 1 M), and addition of 3
 glycerol as a plasticiser. The mixture was mixed under constant 4
 magnetic stirring at 60 °C for 1 h. The solution was cast on a silicone 5
 moulding and placed in an air oven at 50 °C for 24 h. A control keratin 6
 solution (KER-15; 15 wt. % keratin, without glycerol and pH 7
 modification) was used to prepare films using keratin recovered by 8
 $[C_2C_1im][C_1CO_2]$ and $[N_{111(20H)}][C_1CO_2]$, aiming to investigate the IL 9
 influence on the keratin film properties. Then, keratin-cellulose and 10
 keratin-chitin biocomposite films were processed, aiming to 11
 understand the impact of the blend composition on the film 12
 properties. Keratin-cellulose (75:25 and 50:50 w/w) and keratin- 13
 chitin (75:25 and 50:50 w/w) films were processed by adding keratin 14
 and cellulose or chitin in distilled water (15 wt. % of biopolymers). 15
 The film processing followed the previously described procedure for 16
 pure keratin films. The keratin-based film processing is schematically 17
 summarized in Figure 1, and the conditions used for the processing 18
 and their sample names are presented in Table 1.

1 Characterisation of keratin-based films

2 The Fourier transform infrared attenuated total reflectance (FTIR)
3 ATR) spectra of the films processed with different conditions were
4 acquired in a FTIR spectroscopy (Spectrum One FTIR system
5 PerkinElmer, Wellesley, MA). The functional groups available on films

6 were analysed at room temperature, in a frequency range of 4000-
7 400 cm⁻¹, by accumulating 16 scans, with a resolution of 4 cm⁻¹, and
8 an interval of 1 cm⁻¹.

9 Thermogravimetric analysis (TGA) was carried out in a TA Q500 (TA
10 Instruments, USA) TGA analyser. Keratin-based films were placed in

1 an aluminium pan and further analysed under a nitrogen gas at a flow
2 rate of 25 mL·min⁻¹. The samples were heated at a rate of 20 °C·min⁻¹
3 in the temperature range from 30 to 600 °C.

4 To investigate the hydrophilicity of the films, the contact angle was
5 determined using a semi-automatic wettability analysis with high
6 dosing precision (DSA25S, Krüss). Adding a drop of 7 µL of ethylene
7 glycol at a rate of 7 µL·s⁻¹, multiple measurements were made on
8 keratin-based films. Further details on the procedure can be found
9 elsewhere ¹¹.

10 Using a Lloyd EZ 50 testing machine, the tensile strength of the film
11 was determined. Keratin-based films were cut into rectangular
12 shapes (4 cm × 1 cm), and three replicates were carried out. The
13 tensile strength (MPa) was calculated by dividing the obtained value
14 (N) by the cross-sectional area of the films.

15 Scanning electron microscopy (SEM) was performed using a high
16 resolution field-emission Zeiss Auriga Cross Beam. Aiming to ensure
17 the conductivity of the films, they were coated with chromium (5
18 nm) in a Q150 TS machine before the sample analysis. Images were
19 obtained using an accelerating voltage of 5 kV and a working distance
20 of 5 nm.

21 Adsorption properties of keratin-based films

22 The adsorption of RB4 was addressed using keratin-based films with
23 the best achieved properties (high thermal degradation and high
24 tensile strength). First, the adsorption kinetic was investigated using
25 10 mL of RB4 solution (60 ppm) at pH 2.0 with 5 mg of adsorbent for
26 0-360 min. The effect of pH on adsorption performance was studied
27 in a pH range of 2.0-8.0 using 10 mL of RB4 solution (60 ppm) with
28 mg of adsorbent for 300 min. Then, the effect of the initial
29 concentration of RB4 (10-60 ppm) was investigated for all keratin-
30 based films using 5 mg of adsorbent and 10 mL of RB4 solution at
31 pH 2.0 for 300 min. The samples were maintained by stirring (150 rpm)
32 at 30 °C. The dye concentration was determined by a UV-Vis
33 spectrophotometer UV-2600 (Shimadzu) at a wavelength of 595 nm
34 using a previously established calibration curve. The pH modification
35 on dye solutions did not alter the chemical structure of the dye
36 Supporting Information, Figure S2)³⁵. To determine the amount of
37 dye adsorbed, Equation 1 was used:

$$38 \quad q_e = \frac{C_0 - C_e}{m} \times V$$

39 where q_e is the equilibrium adsorption capacity (i.e. the amount of
40 dye-adsorbed (mg·g⁻¹) on the adsorbent at equilibrium), C_0 and C_e are
41 the initial and equilibrium concentrations of dye (mg·L⁻¹)
42 respectively, m is the mass of adsorbent used (mg), and V is the
43 volume of dye solution (L).

44 The adsorption kinetic data generally follow one of the two kinetic
45 models, namely the Pseudo First-Order (PFO) or the Pseudo Second-
46 Order (PSO) models, which are described by the following equations
47 respectively:

$$48 \quad \frac{dq_t}{dt} = k_1 \times (q_e - q_t)$$

$$49 \quad \frac{dq_t}{dt} = k_2 \times (q_e - q_t)^2$$

where k_1 is the PFO constant (min⁻¹) and k_2 is the PSO constant (min⁻¹·
g²·mg⁻¹), q_e is the amount of sorbent bound to the sorbate at the
equilibrium (mg·g⁻¹), q_t is the amount of sorbent bound to the
sorbate at a given time (mg·g⁻¹), and t is the time (min).

Results and discussion

Keratin-based film characterisation

The FTIR-ATR spectra are shown in Figure 2, showing the
essential absorption bands representative of keratin-based
films. The presence of keratin is confirmed by the stretching
vibrations of O–H and N–H (Amide A) at 3670-2800 cm⁻¹, C=O
stretching (Amide I) at 1700-1600 cm⁻¹, N–H bending and C–H
stretching (Amide II) at 1590-1470 cm⁻¹, and amide III (1280-
1200 cm⁻¹). In general, all keratin films present the same bands,
except for the keratin films obtained by adding glycerol as a
plasticiser, where a band at 1070-1000 cm⁻¹ is also observed,
being indicative of the presence of the added alcohol ³⁶.
Regarding the blends, the hydroxyl group broad stretching at
3300 cm⁻¹ and 1650 cm⁻¹ are related to the water absorption
and hydroxyl groups present in the cellulose ³⁷, while the band
at 1060 cm⁻¹ is attributed to the C-O asymmetric stretching
vibration of the glycosidic ring in cellulose ³⁸. The bands at 1650
cm⁻¹ and 1560 cm⁻¹ are related to chitin's amide vibrations,
assigned to the C=O stretching and N-H bending ³⁹. Overall,
these results reveal that the biopolymers are well blended.

Regarding the thermal behaviour (Supporting Information,
Figure S3), all keratin-based films presented more than one step
of degradation, with the first degradation step, likely related to
moisture, occurring at below 100 °C. The second stage
corresponds to keratin decomposition for pure keratin films
(without adding cellulose or chitin). All keratin film samples
(prepared with different ILs, solution pH, keratin concentration,
and glycerol added) were stable up to 215 °C and revealed a
similar behaviour. The biocomposite blends (with different
ratios of keratin-cellulose and keratin-chitin) exhibited similar
behaviour and were stable up to 160 °C. The samples were
decomposed between 160 °C and 360 °C, with a slow
degradation, divided into steps, thus indicating physical
interactions, and no chemical interactions, between the
biopolymers (the thermal degradation of cellulose and chitin
correspond to 335 °C ⁴⁰ and 253 °C ⁴¹, respectively). The starting
decomposition at 160 °C can be related to glycerol evaporation
(boiling temperature = 182 °C). In general, the results are within
the range of the thermal degradation obtained for keratin ^{6,11,42}
and other protein films, such as soy protein films (180 °C) ⁴³ and
whey protein films (295 °C) ⁴⁴.

The wettability of keratin-based films was assessed by
measuring the contact angle of ethylene glycol drops on the
films (Table 2). The contact angle of all keratin-based films was
found to be lower than 90°, confirming their hydrophilic nature
due to the presence of hydrogen bond donor and acceptor
groups, such as amino, carboxylic and hydroxyl groups.
Furthermore, no significant variances in the contact angle were
observed across different IL films, ranging from (55 ± 1)° to (60
± 5)°, meaning that there is no IL residue on the keratin-based
films and that their use in keratin processing does not cause
significant differences in keratin properties. Nevertheless, when
keratin films were prepared with higher pH, the contact angle
value increased from (55 ± 1)° to (84 ± 1)°, indicating that

1 increasing pH can promote a more a hydrophobic film. This
 2 behaviour is attributed to the alkaline pH, which results in
 3 stronger intramolecular electrostatic repulsion and unfolding of
 4 proteins, exposing their hydrophobic groups and amino acid
 5 residues. Furthermore, the films with glycerol were more
 6 hydrophilic, which is due to its plasticiser effect and the
 7 presence of additional polar hydroxyl groups. The addition of
 8 wt. % glycerol decreased the contact angle from $(55 \pm 1)^\circ$ to $(46 \pm 5)^\circ$. The same behaviour was observed by Cerqueira et al.⁴⁵ who investigated the influence of glycerol on chitosan films.⁴⁵ The wettability of the keratin-cellulose and keratin-chitin films range from $(47 \pm 2)^\circ$ to $(63 \pm 3)^\circ$, supporting their hydrophilic nature. For the keratin-cellulose films, increasing the cellulose content from 25 wt. % to 50 wt. % resulted in a rise of 9° in the contact angle for films produced with both ILs. This is a direct result of the higher cellulose hydrophobic nature. A contrasting

FTIR spectra of keratin-based film samples processed using different conditions: varying protein concentration (A); pH of the solution (B); addition of glycerol (C); using different acetate-based ILs (D); keratin-cellulose blend films processed by $[C_2C_1im][C_1CO_2]$ (E); keratin-chitin blend films processed by $[C_2C_1im][C_1CO_2]$ (F); keratin-cellulose blend films processed by $[N_{111(20H)}][C_1CO_2]$ (G); and keratin-chitin blend films processed by $[N_{111(20H)}][C_1CO_2]$ (H).

ARTICLE

behaviour was observed for keratin-chitin films, with the contact angle decreasing by 16° when chitin addition increased from 25 wt. % to 50 wt. %. This behaviour can be attributed to the interaction between the biopolymers, leading to a high exposure of their hydrophilic amino acids. Deng et al.⁴⁶, who processed wool keratin-cellulose membranes with different ratios, also obtained hydrophilic biomaterials, with changes in the contact angle from 61° to 80°. To the best of our knowledge, no results regarding keratin-chitin films have been reported. Tomihata et al.⁴⁷ evaluated the contact angle of chitin films and obtained 69.5°, thus confirming the hydrophilicity of chitin films. Tensile strength refers to the ability of a film to resist tensile stress before breaking, being the results obtained for the investigated keratin-based films summarised in Table 2. The tensile strength of keratin films increased 26 times by increasing keratin concentration from 5 wt. % to 15 wt. %, ranging from (0.53 ± 0.04) MPa (KER-5) to (14 ± 2) MPa (KER-15). No further increase in the tensile strength was observed when increasing

keratin concentration from 15 wt. % (KER-15) to 20 wt. % (KER-20). Concerning the pH and use of various ILs, no significant differences were observed. The addition of glycerol as a plasticiser increased the tensile strength of the film 3.5 times, going from (14 ± 2) MPa (KER-gly0) to (50 ± 1) MPa (KER-gly10). Therefore, among the variables evaluated in this work, the keratin concentration and glycerol addition presented the highest impact on the films' tensile strength. Shahrim et al.⁴⁸ also observed this glycerol effect while investigating the tensile strength of starch films. The results obtained by the authors revealed an increase in tensile strength of 7 % when increasing the glycerol from 5 % to 10 %⁴⁸, which is lower than the increase observed with the keratin films studied here. For the blends, the tensile strength of keratin-cellulose films did not present a significant increase when the addition of cellulose increased from 25 wt. % to 50 wt. %. Furthermore, increases of 1.1 and 1.4 times were observed for the films processed with keratin dissolved by [N₁₁₁(2OH)][C₁CO₂] and [C₂C₁im][C₁CO₂], respectively.

1 These results suggest that using $[C_2C_{1im}][C_1CO_2]$ for dissolution
 2 leads to more resistant films. The maximum tensile strength
 3 obtained for the keratin-cellulose blend was (30 ± 3) MPa
 4 achieved with KER-CELL-C2 50:50. On the other hand
 5 considering blends with chitin, the highest tensile strength of
 6 ± 1 MPa was obtained for KER-CHI-C2 50:50, demonstrating the
 7 benefit of adding chitin due to its more promising mechanical
 8 properties⁴⁹.
 9 Ma et al.⁵⁰ prepared keratin-cellulose films with various ratios
 10 and showed that the blends have poor mechanical properties
 11 compared to pure cellulose films. According to the authors, the
 12 pure cellulose film had a higher tensile strength (44 MPa) than
 13 a keratin-cellulose 40:60 film (28 MPa)⁵⁰. The authors did not
 14 report films with higher amounts of keratin; however, their
 15 results show that more cellulose could be essential to create a
 16 stronger film. Concerning the authors' process, keratin was
 17 recovered from wool using urea, sodium dodecyl sulphate, and
 18 sodium bisulphite. After protein dialysis, the liquid was cast
 19 a polypropylene mould, dried, and dissolved in formic acid
 20 to prepare a keratin solution. Another solution was prepared for
 21 cellulose by dissolving the polysaccharide in NMMO solution
 22 under heating. On the other hand, to the best of our knowledge,
 23 no results have yet been reported for keratin-chitin films.
 24 However, looking for pure chitin films, Wu et al.⁴⁹ obtained a
 25 high tensile strength value for their films (320 MPa), confirming
 26 chitin's high tensile strength.
 27 The morphological properties of keratin films (Supporting
 28 Information, Figure S4) were appraised using SEM. All keratin
 29 films, except KER-pH12 and KER-gly10, present a smooth
 30 surface. In KER-pH12, a particular behaviour can be noticed due
 31 to the presence of salt (in this case, NaOH, used to adjust the

View Article Online
 DOI: 10.1039/C4SY00176E
 solution pH). In contrast, the roughness in KER-gly10 may be
 due to the addition of glycerol and solution destabilization
 during casting and drying. SEM analysis was also performed to
 illustrate the morphological effects of keratin-blend films, being
 shown in Supporting Information, Figure S5. In general, the
 films are homogeneous, suggesting an appropriate blending;
 however, there were some irregularities observed in the
 blended films, indicating the presence of biopolymer particles
 on the film's surface, which can be related to possible
 differences in coagulation for each biopolymer.

Dye adsorption using keratin-based films

With the aim of preparing stronger keratin-based films for dye adsorption studies, the films processed with $[C_2C_{1im}][C_1CO_2]$ were selected due to their superior mechanical properties, specifically tensile strength (see Table 1). Keratin (KER-gly10), keratin-cellulose (KER-CEL-C2 50:50), and keratin-chitin films (KER-CHI-C2 50:50) were applied to investigate the effects of the biopolymers on dye adsorption. Different adsorption experiments were carried out by varying the RB4 initial concentration, pH, time and adsorbent type. First, aiming to understand the adsorption process and identify the contact time necessary to achieve the equilibrium stage, adsorption kinetic experiments were performed for the KER-CHI-C2 film at pH 2.0, from 0 to 360 min (Figure 3A). Then, the pH effect (from 2.0 to 8.0) was evaluated for the same adsorbent at 300 min (Figure 3B). The respective parameters from the fitting of adsorption kinetic experimental data with PFO and PSO models are given in Table 3.

Figure 3. Adsorption kinetics curves for KER-CHI-C2 film as a function of time (A) and the effect of pH on the adsorption of RB4 by KER-CHI-C2 (B).

Table 3. Adsorption parameters obtained from the fitting of adsorption kinetic experimental data with PFO and PSO models alongside the respective correlation coefficients.

PFO model			PSO model		
q_e ($mg \cdot g^{-1}$)	k_1 (min^{-1})	R^2	q_e ($mg \cdot g^{-1}$)	k_2 (min^{-1})	R^2
18.82	0.0084	0.96	24.86	0.0003	0.95

ARTICLE

1 According to the adsorption kinetic curves (Figure 3A), the
2 equilibrium stage was achieved between 240 and 360 min and
3 maintained for 300 min in the next experiments. Looking at
4 Table 3, despite both models presenting a good fit to the
5 experimental data, PFO presented the best fit ($R^2 = 0.96$)
6 suggesting that the adsorption process occurs on localised sites
7 and does not involve interactions with the adsorbed molecules
8 ⁵¹.

9 By decreasing the pH from 8.0 to 2.0 (Figure 3B), a significant
10 increase in RB4 removal is obtained for KER-CHI-C2, moving
11 from 7.3 % to 15.7 %. This behaviour can be explained by the pH
12 value at zero potential point of the keratin-based films (4 - 5),
13 which means that in acidic conditions the adsorbent is
14 protonated, promoting electrostatic interactions with the dye.
15 RB4 has two sulfonate groups and a primary amino group, with
16 pKa values at 0.8 and 7.0, respectively. These groups can be
17 easily dissociated; thus, the dye molecule has negative and
18 positive charges under the working experimental conditions.
19 The diverse keratin functional groups (e.g. $-NH_2$, $-COOH$, $-SH$
20 and $-OH$) make it a promising adsorbent ⁵². Accordingly, the
21 adsorption mechanism of keratin-based films for RB4 dye is
22 mainly ruled by electrostatic attractions (between the $-NH_2$
23 group of keratin and the sulfonate ($-SO_3^-$) group on RB4
24 structure) and hydrogen bonding interactions (between the $-OH$
25 group of keratin and the nitrogen group on RB4 structure) ^{24,53}.

26 Adsorption isotherms

27 Adsorption isotherms were determined to investigate the
28 relationship between the adsorbent and the dye adsorbed at
29 equilibrium conditions. The two models most widely used to
30 represent equilibrium isotherms for adsorbent materials were
31 applied: the Langmuir and Freundlich models ⁵⁴.

32 Langmuir (Equation 4) is a model based on homogeneous
33 monolayer adsorption on a homogeneous surface, while
34 Freundlich (Equation 5) is based on heterogeneous adsorption
35 ⁵⁴.

$$q_e = q_{max} \times \frac{k_L \times C_e}{1 + k_L \times C_e} \quad (4)$$

where q_{max} is the maximum adsorption capacity of the adsorbent ($mg \cdot g^{-1}$), k_L is the Langmuir constant ($L \cdot mg^{-1}$), C_e corresponds to the dye concentration in the solution ($mg \cdot L^{-1}$), and q_e is the adsorption capacity of the adsorbent ($mg \cdot g^{-1}$), at the equilibrium.

$$q_e = k_f \times C_e^{\frac{1}{n}} \quad (5)$$

where k_f is the Freundlich constant related to the adsorption capacity ($mg \cdot g^{-1} \cdot (L \cdot mg^{-1})^{1/n}$) and n is an empirical parameter related to adsorption intensity.

Figure 4 shows the Langmuir and Freundlich's fittings for all keratin-based films at pH 2.0. The parameter values of the Langmuir and Freundlich isotherms and the related correlation coefficients (R^2) are reported in Table 4. Both models presented satisfactory fittings; however, the Langmuir model yielded the better fitting, showing R^2 values higher than 0.92. This trend indicates that the dye adsorption on the adsorbent occurs in a homogeneous surface with monolayer sorption ⁵⁴ and that the adsorption is of chemical nature ⁵⁵. These results are in accordance with the previously discussed results, where it was shown the relevance of the pH and of electrostatic interactions between the dye and the polymers. Furthermore, the maximum adsorption capacity obtained in this work ($55.71 mg \cdot g^{-1}$) for KER-C2 film confirms that keratin is a fibrous protein with diverse functional groups (e.g. hydrophobic and hydrophilic amino acids and carboxyl groups) ^{14,23,24}, acting as an efficient adsorbent for RB4.

Figure 4. Experimental adsorption isotherms of RB4 at pH 2.0 using different keratin-based films: KER-CHI-C2 (A); KER-CELL-C2 (B); and KER-C2 film (C).

Table 4. Parameters obtained for RB4 adsorption using the Langmuir and Freundlich models.

Samples	Model	Parameter	Value	R ²
KER-CHI-C2	Langmuir	q_{max} (mg·g ⁻¹)	18.35	0.97
		k_L (L·mg ⁻¹)	0.05	
	Freundlich	k_f ((mg·g ⁻¹)·(L·mg ⁻¹) ^{1/n})	1.81	0.98

1 According to the results depicted in Figure 4, the highest
2 adsorption capacity (55.71 mg·g⁻¹) obtained in this work for RB4
3 dye is comparable to other adsorbents reported in the
4 literature, such as chitosan-glutaraldehyde beads (1.8 mg·g⁻¹)⁴⁵
5 and cellulose-epichlorohydrin polymers (69.8 mg·g⁻¹)⁵⁷.

6 Conclusions

7 In this study, a sustainable approach for keratin recovery from
8 chicken feather waste was employed, allowing to prepare
9 keratin-based films, either in their pure form or blended with
10 chitin and cellulose. Various processing conditions were
11 investigated to improve the film mechanical properties. Our
12 findings confirmed that keratin-based films' mechanical
13 properties, particularly the tensile strength, can be improved,
14 principally by increasing the protein concentration and by
15 adding glycerol or with keratin-chitin blends.

16 To evaluate the use of keratin-based films as adsorbent
17 materials, RB4 adsorption tests were performed at different
18 conditions. RB4, a toxic and widely used dye in the textile
19 industry, was efficiently removed by decreasing the pH.
20 Moreover, the Langmuir isotherm better described the
21 obtained experimental results, indicating that the RB4
22 adsorption occurs in a monolayer and is of a chemical nature.
23 Overall, the maximum adsorption capacity obtained in this work
24 (55.71 mg·g⁻¹) for KER-C2 film confirms the efficiency of keratin
25 as an adsorbent due to its functional groups (e.g. e.g. -NH₂,
26 COOH, -SH, and -OH). As future steps, evaluating the recycling
27 and reuse of keratin-based films (e.g. by desorption) is crucial
28 to attend to a more sustainable process.

29 Overall, this work brings new perspectives for chicken feather
30 waste valorisation, recovering keratin and processing keratin-
31 based films (pure or blend with cellulose or chitin) that can be
32 successfully used as adsorption biomaterials. This attempt
33 shows the promise of keratin-based films for dye removal,
34 addressing the possibility of chicken feather' economic
35 valorisation and overcoming the challenging removal of water-
36 soluble dyes using a renewable, sustainable, and low-cost
37 biomaterial. Notably, our investigation also marks the first
38 reported results on the development of keratin-chitin films,
39 proving that chitin can be used instead of chitosan, and whose
40 industrial production still produces high amounts of liquid
41 effluents from the deacetylation of chitin with concentrated
42 NaOH⁵⁸.
