## Introduction

Since the first observation of spin-crossover (SCO) in an  $\text{Fe}^{\text{II}}$  compound was reported in 1964,<sup>1</sup> the phenomenon has fascinated both physicists and chemists alike. While its origin was readily identified, the effects of SCO on changes in volume, entropy, dielectricity and colour have driven an extensive line of research in view of possible fabrication of memory devices for applications. As the physical properties are being explained theoretically, chemists have been producing endless variations of materials with designable structures of all dimensionalities. In addition, other physical and chemical properties have been incorporated in view of developing multifunctional intelligent materials.<sup>2</sup> Up to now, a large number of complexes have been prepared from metal ions with  $d^4$ – $d^7$  electronic configurations using a variety of ligands.<sup>3</sup> The most notable systems are those based on metals with the  $d^6$  configuration, such as  $\text{Fe}^{\text{II}}$ , that exhibit bi-

stability around room temperature, where the transitions can be tuned by various external physical perturbations; these include temperature, pressure, light or X-ray irradiation, and intense magnetic fields, as well as chemical stimuli such as a change in the guest molecules or by their removal or inclusion.<sup>2c–f,4</sup> Significant research efforts are focused on widening the hysteresis width around room temperature.<sup>2b,5</sup> From a chemistry perspective, the development of  $\text{Fe}^{\text{II}}$  based SCO has evolved from complexes containing solely nitrogen donor ligands such as pyridine due to its moderate ligand field, to those containing both nitrogen and oxygen donors, such as Schiff-base ligands. In this context, Kou *et al.* achieved multifunctional SCO in two  $\text{Fe}^{\text{II}}$ –Schiff-base complexes which displayed SCO at *ca.* 300 K, which was controllable by dehydration-hydration.<sup>6</sup> Recently, Weber *et al.* investigated a one-dimensional (1D) SCO polymer  $[\text{Fe}^{\text{II}}(\text{L}_1)(4,4'\text{-bpy})]_n$  ( $\text{L}_1$  is a  $\text{N}_2\text{O}_2^{2-}$  coordinating Schiff-base bearing a phenazine fluorophore) possessing a 48 K wide hysteresis above 300 K, where the SCO could also be monitored by the ligand luminescence.<sup>7</sup>

Thus, the idea of functionalizing a Schiff-base ligand with a probe segment is an effective strategy to develop switchable SCO materials. In this regard, a new approach is the development of a system incorporating a redox-active pendant to control the  $\text{Fe}^{\text{II}}$  SCO transition. Tetrathiafulvalene (TTF), a sulphur-rich conjugated molecule possessing two reversible and easily accessible oxidation states (*i.e.*, radical  $\text{TTF}^{\cdot+}$  and diamagnetic  $\text{TTF}^{2+}$ ), represents a potential molecule that can be appended to a Schiff-base. TTF is well known as an appealing electron donor, and exhibits rich redox chemistry that underpins its application in studies of electrochromic materials,

<sup>‡</sup> These authors contributed equally to this work.

electrocatalysis and photoconductive switches.<sup>3f,8</sup> Furthermore, complexes bearing TTF are highly capable of stacking into supramolecular structures and facilitating efficient pathways for charge transport due to  $\pi\cdots\pi$  and S···S interactions.<sup>9</sup>

In view of the fascinating structures that have been reported for TTF functionalized ligands, such as TTF-(1,2,3-triazole), tetra(4-pyridyl)-TTF, and tetra(4-benzoate)-TTF, in coordination compounds,<sup>3f,8c,9b,10</sup> we have appended TTF to a Schiff-base. By adding the redox activity of the TTF to the  $\text{N}_2\text{O}_2$  square planar unit of the Schiff-base, we propose the development of a new class of multifunctional SCO materials (Scheme 1). In this context, only one mononuclear  $\text{Fe}^{\text{II}}$  ligated to a tetrathiafulvalene-functionalized dipyridophenazine has been reported to date.<sup>11</sup> Both thermal spin-crossover (*ca.* 143 K) and a wide hysteresis of 48 K were observed. Cyclic voltammetry in solution identified the two oxidation steps of the TTF. However, in the absence of structural analyses of the low-spin state and dielectric measurements, no further insights were gleaned into the coexisting redox and SCO properties. Herein, we report a new  $\text{Fe}^{\text{II}}$  SCO 1D-polymer,  $[\text{Fe}^{\text{II}}(\text{L})(\text{bpy})]_n$  (1), with an additional bridging 4,4'-bpy. This new material is found to be an exemplary compound displaying a concerted tandem cooperation between the SCO and dielectricity. While the dielectric anomaly is often explained by the contraction of the Fe octahedron from high-spin (HS) to low-spin (LS), we propose a further reason for enhancing the effect which is driven by bending of the TTF moiety, altering the magnitude and direction of the dipole moment.

## Experimental section

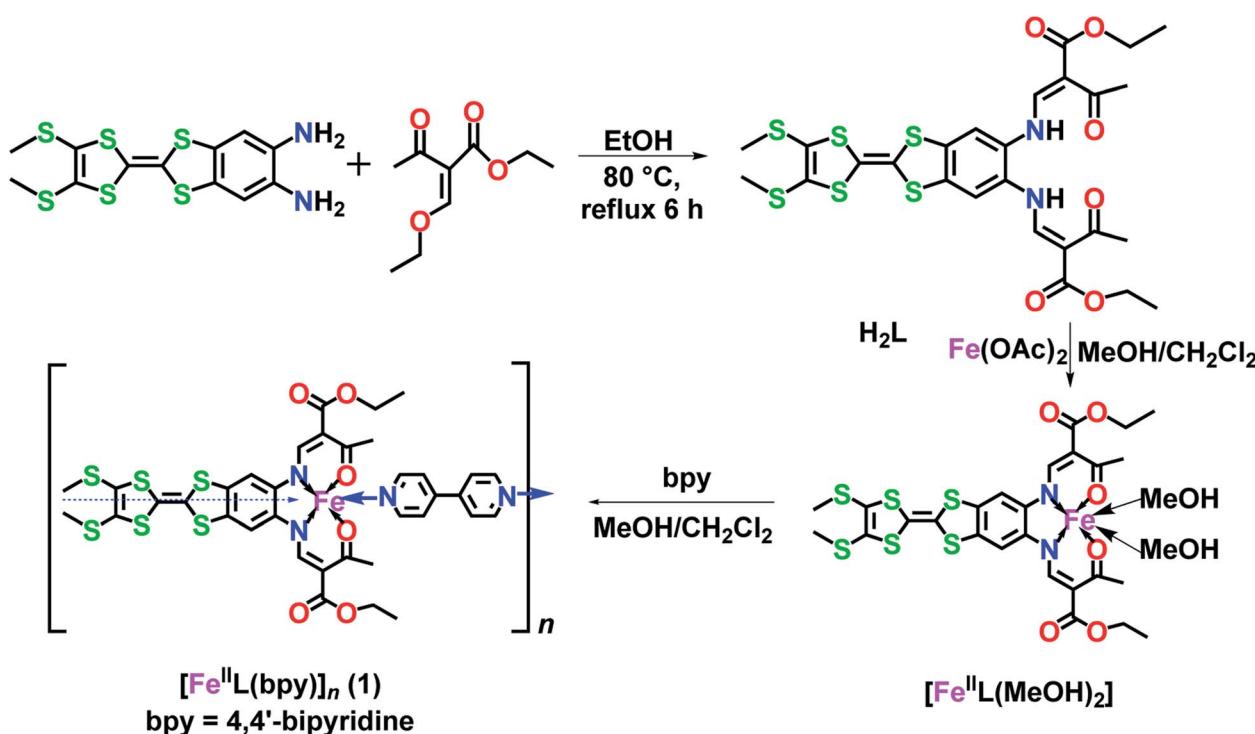

The methods used for elemental analyses, thermogravimetry, infrared spectroscopy, single crystal X-ray diffraction data collection and the structural analyses, magnetic, optical and electrical property determinations as well as the DFT calculations are detailed in the ESI† to avoid repetition from our previous works. The preparation of  $[\text{Fe}^{\text{II}}\text{L}(\text{bpy})]$  was realized in three steps as follows from  $\text{H}_2\text{L}$ ,  $[\text{Fe}^{\text{II}}\text{L}(\text{MeOH})_2]$ , and  $[\text{Fe}^{\text{II}}\text{L}(\text{bpy})]$ .

### Synthesis of ligand $\text{H}_2\text{L}$

2-(4,5-Bis(methylthio)-1,3-dithiol-2-ylidene)benzo[*d*][1,3]dithiole-5,6-diamine (376 mg, 1 mmol) and ethyl 2-acetyl-3-ethoxyacrylate (559 mg, 3 mmol) were dissolved in 15 mL ethanol and heated at reflux for 6 h. After cooling to 25 °C,  $\text{H}_2\text{L}$  (orange-yellow solid) was collected by filtration. Yield: 550 mg (84%). Anal. calc. for  $\text{C}_{26}\text{H}_{28}\text{N}_2\text{O}_6\text{S}_6$ : C 47.54, H 4.30, N 4.26, S 29.29%; found: C 47.33, H 4.15, N 4.06, S 29.15%.  $^1\text{H}$  NMR (400 MHz,  $\text{CDCl}_3$ , ppm):  $\delta$  12.95 (d,  $J = 12.1$  Hz, 1H), 8.27 (d,  $J = 12.1$  Hz, 2H), 7.13 (s, 1H), 4.27 (q,  $J = 7.1$  Hz, 4H), 2.57 (s, 3H), 2.45 (s, 3H), 1.34 (t,  $J = 7.1$  Hz, 6H). IR (KBr pellet,  $\text{cm}^{-1}$ ): 2980 (w), 1700 (s), 1635 (s), 1580 (s), 1404 (m), 1254 (s), 1195 (m), 1066 (s), 774 (m).

### Synthesis of $[\text{Fe}^{\text{II}}\text{L}(\text{MeOH})_2]$

$\text{H}_2\text{L}$  (132 mg, 0.2 mmol) and anhydrous ferrous acetate (42 mg, 0.24 mmol) were dissolved in 5 mL  $\text{CH}_2\text{Cl}_2$  and 15 mL MeOH in

Scheme 1 Design approach for a TTF-Schiff-base ligand ( $\text{H}_2\text{L}$ ) and its iron(II) precursor  $[\text{Fe}^{\text{II}}(\text{L})(\text{MeOH})_2]$  used in the formation of the 1D-spin-crossover polymer  $[\text{Fe}^{\text{II}}(\text{L})\text{bpy}]_n$ .

a N<sub>2</sub> glove box. After stirring overnight at 25 °C, the resulting dark green solid of [Fe<sup>II</sup>L(MeOH)<sub>2</sub>] was collected by filtration. Yield: 100 mg (65%, based on H<sub>2</sub>L). Anal. calc. for C<sub>28</sub>H<sub>34</sub>·FeN<sub>2</sub>O<sub>8</sub>S<sub>6</sub>: C 43.40, H 4.42, N 3.62, S 24.83%; found: C 43.16, H 4.18, N 3.49, S 24.53%. IR (KBr pellet, cm<sup>-1</sup>): 2975 (w), 1711 (s), 1628 (s), 1589 (m), 1427 (s), 1379 (m), 1261 (s), 1073 (s), 849 (w), 774 (w).

### Synthesis of [Fe<sup>II</sup>L(bpy)]<sub>n</sub> (1)

[Fe<sup>II</sup>L(MeOH)<sub>2</sub>] (50 mg, 65 µmol) and bpy (11 mg, 70 µmol) were dissolved in 15 mL CH<sub>2</sub>Cl<sub>2</sub> and 5 mL MeOH in a glove box. After stirring overnight at room temperature, the mixture was filtered and black needle crystals of [Fe<sup>II</sup>L(bpy)] were collected after partial vaporization of the solvents. Yield: 38 mg (68%, based on [Fe<sup>II</sup>L(MeOH)<sub>2</sub>]). Anal. calc. for C<sub>36</sub>H<sub>34</sub>FeN<sub>4</sub>O<sub>6</sub>S<sub>6</sub>: C 49.88, H 3.95, N 6.46, S 22.19%; found: C 49.63, H 3.75, N 6.29, S 22.01%. IR (KBr pellet, cm<sup>-1</sup>): 2921 (w), 1684 (s), 1587 (s), 1427 (s), 1261 (s), 1197 (w), 1073 (m), 852 (w), 771 (w).

## Results and discussion

Due to the very rapid loss of solvent of crystallization all reported measurements (including magnetic susceptibility, differential scanning calorimetry, dielectric permittivity, solid-state cyclic voltammetry, and electrical conductivity), except that for single-crystal diffraction at 123 K, were performed on fully desolvated samples.

At 123 K, the triclinic *P*-1 unit-cell of **1** contains one Fe, one TTF-Schiff-base and one bpy (Table 1). The Fe<sup>II</sup> (Fe1) adopts a distorted octahedron where two nitrogen atoms (N1 and N2) and two oxygen atoms (O1 and O2) from the TTF-Schiff-base

form the basal plane, and two nitrogen atoms from the bridging bpy (N3 and N4) occupy the apical positions. The sum of angles between the basal atoms is 360°, suggesting that the atoms Fe1, O1, O2, N1, and N2 share the same plane. The axial N3–Fe1–N4 angle of 175.4° indicates that the Fe1, N3, and N4 are nearly in a line. Each bpy bridges two Fe<sup>II</sup> to construct linear 1D ···Fe–bpy–Fe–bpy··· chains, and short S···S contacts between the TTF moieties of adjacent parallel chains, leading to ladders (Fig. 1 and S1†). Intermolecular interactions (C2···O1) result in a two-dimensional (2D) network. The average Fe1–N and Fe1–N<sub>bpy</sub> bond lengths are 1.982 and 2.100 Å, respectively, and lie within the range reported for low-spin Fe<sup>II</sup> (Fe1) compounds.<sup>3c,12</sup>

Upon heating to 350 K, the key structural features measured at 123 K remain, but the Fe<sup>II</sup> (Fe1) forms longer bonds (average Fe1–N of 2.079 Å, Fe1–N<sub>bpy</sub> of 2.197 Å, and Fe1–O of 1.994 Å), characteristic of reported compounds in the HS state.<sup>7,12,13</sup> The in-chain Fe···Fe separations are 11.34 Å (123 K) and 11.36 Å (350 K). In addition to the expansion of the Fe<sup>II</sup> (Fe1) coordination sphere, the angles in the LS state tend to increase upon changing to HS. The angles O1–Fe1–O2 = 99.1° and average N1–Fe1–N2 = 82.2° at 123 K, become 110.1° and 79.7° at 350 K. Selected bond lengths and angles are listed in Table S1.†

The most striking difference between the LS and HS structures is the change of the TTF from planarity at 123 K to a puckered shape at 350 K (Table 2). The dihedral angle between the two pseudo-planar 5-membered rings about the central C=C bond is 18.2° (LS) and 34.7° (HS), respectively. These changes suggest that thermal vibrations may cause configuration distortion. The severe distortion is accompanied by a considerable change in orientation as demonstrated by the S···S contacts of 3.80 Å at 123 K (LS state) to 3.57 Å at 350 K (HS

state). By centring the Fe and aligning the Fe–N<sub>bpy</sub> bond in a superposition picture of the two structures (Fig. 2), several major structural changes in the pendant fragments of the Schiff-base are evident, as well as the rotation of the pyridine of the bpy.

The magnetic susceptibility was measured between 2 and 400 K on cooling and warming in a 1 kOe field using a SQUID magnetometer (Fig. S2†). The  $\chi_{\text{M}}\text{T}$  value is  $3.35 \text{ cm}^3 \text{ K mol}^{-1}$  at 400 K, which is consistent with that expected for HS Fe<sup>II</sup>.<sup>7,12c</sup> On cooling,  $\chi_{\text{M}}\text{T}$  decreases slowly to  $2.90 \text{ cm}^3 \text{ K mol}^{-1}$  until 330 K.

Upon further lowering the temperature, a sharp drop to  $0.48 \text{ cm}^3 \text{ K mol}^{-1}$  at 310 K is observed, indicating that a major fraction of the Fe<sup>II</sup> centres are now in a LS state.<sup>7,12c</sup> Below 300 K,  $\chi_{\text{M}}\text{T}$  is almost constant at  $0.24 \text{ cm}^3 \text{ K mol}^{-1}$ . Upon warming, it follows a similar trend but with a hysteresis of 8.1 K around the SCO transition (326.6 K for cooling and 334.7 K for warming, Fig. 3). At 300 and 90 K the EPR spectra are silent eliminating the possibility of the formation of a radical TTF (Fig. S3†).

Differential Scanning Calorimetry (DSC) measurements (Fig. 3 and S4†) were performed at different cooling and warming rates of 15, 10 and 5 K min<sup>-1</sup>. The results show an endothermic change at 331.3 K on cooling and an exothermic one at 324.9 K on warming, corresponding to the SCO transition and matching the magnetization data. The integrated enthalpy and entropy values are  $\Delta H = 6.78 \text{ kJ mol}^{-1}$  and  $\Delta S = 20.9 \text{ J mol}^{-1} \text{ K}^{-1}$  for the HS to LS transition, and  $\Delta H = 6.07 \text{ kJ mol}^{-1}$  and  $\Delta S = 18.3 \text{ J mol}^{-1} \text{ K}^{-1}$  for the LS to HS transition, which are consistent with those reported in the literature.<sup>3c,12c,14</sup>

The variation of the complex dielectric permittivity ( $\varepsilon = \varepsilon' - i\varepsilon''$ ) was measured on two different samples by cycling the temperature ( $20 \text{ K min}^{-1}$ ) from 290 to 363 K at different frequencies of 0.5, 1, 5, 10, 100, and 1000 kHz (Fig. 3 and S5†). There were anomalies discernible. Between 310 and 350 K there is a hysteresis accompanying the SCO transition. While the

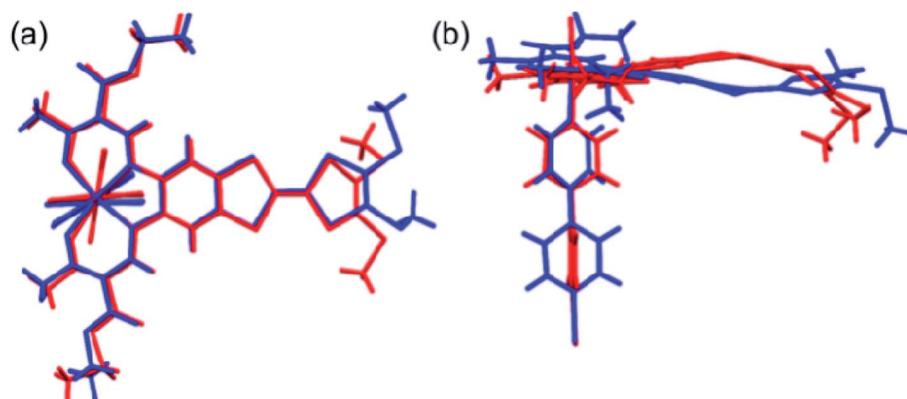

Fig. 2 Top (a) and side (b) views of the superposition of the basic molecular skeletons of the structures at 123 K (blue) and 350 K (red).

value of the real part ( $\epsilon'$ ) is low at 350 K and high at 310 K for all frequencies, that of the imaginary part goes from high to low at 500 Hz and gradually reverses from low to high between 1 and 5 kHz. The hysteresis width is independent of the frequency. The hysteresis in the real part goes from high in the HS state to low in the LS state. The maximum value of  $\epsilon'$  is *ca.* 14 for the frequency of 500 Hz, and this dielectric constant value is higher than that for most of the investigated SCO materials (Table S2†).<sup>14c,15</sup> Both the reversed hysteresis and the enhancement are in contrast to what have been observed previously for compounds without the redox-active ligand. The presence of these two anomalies are considered to be driven by two concomitant effects, namely, the size change and bending of TTF.

The transition temperatures ( $T_{1/2}\downarrow$  and  $T_{1/2}\uparrow$ ), as well as the width of the thermal hysteresis ( $\Delta T$ ), and the change in  $\epsilon'$  during the SCO transition ( $\Delta\epsilon' = \epsilon'_{\text{HS}} - \epsilon'_{\text{LS}}$ ) are also in agreement with the DSC and magnetization data (Fig. 3).<sup>16</sup> Upon HS  $\leftrightarrow$  LS spin crossover, the variation in dielectric constant originates from the size of the breathing of the Fe octahedron and in the present case, additionally to the bending of the TTF during the SCO transition.<sup>17,18</sup>

The electrochemical properties of **1** as a solid material were investigated to gain insight into the prospects for redox modulation of the components. Cyclic voltammetry (CV) measurements in 0.1 M  $[(n\text{-Bu})_4\text{N}]\text{PF}_6$  in  $\text{CH}_3\text{CN}$  supporting electrolyte (Fig. S6†) revealed a  $1\text{e}^-$  oxidation for TTF to  $\text{TTF}^{+}$  at 0.11 V followed by a multi-electron wave at  $\sim 0.5$  V. The latter occurs at a voltage consistent with oxidation of  $\text{TTF}^{+}$  to  $\text{TTF}^{2+}$ .<sup>11,19</sup> At more anodic potentials, multiple irreversible processes were observed in the CV; the origin of these processes is tentatively ascribed to oxidation of the organic moieties of L.

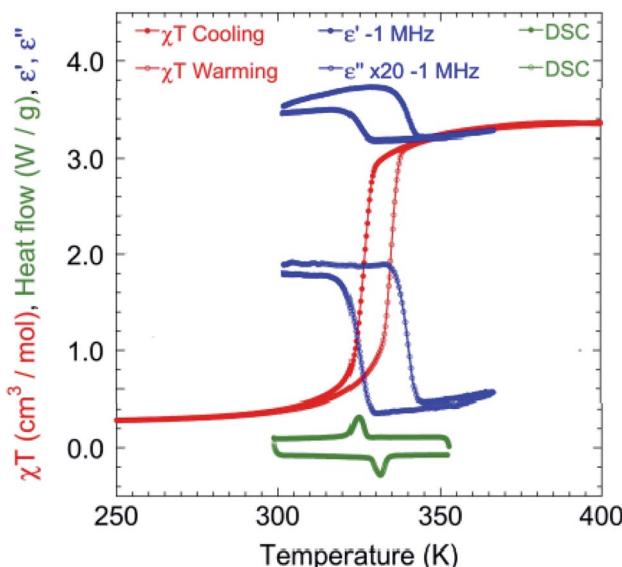

Fig. 3 Temperature dependence of  $\chi_M T$  in 1 kOe (red) at a rate of  $2\text{ K min}^{-1}$  (see Fig. S2† for the full temperature range of  $\chi_M T$ ), real and imaginary ( $\times 20$ ) dielectricity (blue) at a rate of  $20\text{ K min}^{-1}$  and DSC (green) at a rate of  $15\text{ K min}^{-1}$  around the HS–LS transition.

Table 3 Energies, electric dipole moments, dipole moment vectors, spin densities, Mulliken charges at the b3lyp/6-31G\*\*levels for 1

Spin state	Free energy (eV)	Dipole moment (Debye)	Dipole moment vector	Spin density (Fe)	Mulliken charges (Fe)
High spin (quintet)	-12 449, 2.07	4.37			
Low spin (singlet)	-12 449, 2.58	9.51			
b3lyp/6-31G**					
				0.68 (3.66)	0.44 (0.00)

A contribution from the  $\text{Fe}^{\text{II/III}}$  couple was discounted, as a related Schiff-base iron ligand has previously been shown to have a quasi-reversible  $\text{Fe}^{\text{II/III}}$  couple at potentials below  $-1\text{ V}$  (vs.  $\text{Fc}/\text{Fc}^+$ ).<sup>20</sup> As the potential was swept back to  $0\text{ V}$ , the reverse processes were suggestive of reduction, however they were clearly irreversible. The second cycle of the CV experiment showed only two reversible  $1\text{e}^-$  oxidation steps for the TTF to its  $\text{TTF}^{\cdot+}$  and  $\text{TTF}^{2+}$  forms. These observations are tentatively attributed to decomposition and dissolution of the material at a voltage above  $0.5\text{ V}$ , such that only solution-based processes for the electrochemically active TTF constituents are observed. Indeed, subsequent runs show progressive diminishing intensity of the waves until the CV becomes largely featureless.

The electrical conductivity was measured between  $300$  and  $350\text{ K}$  on warming in a Quantum Design SQUID physical property measurement system (PPMS) at the rate of  $1\text{ K min}^{-1}$  (Fig. S7†). The electrical conductivity of **1** is  $1.42 \times 10^{-8}\text{ S cm}^{-1}$  at  $300\text{ K}$  and decreases gradually upon warming to a minimum of  $8.07 \times 10^{-9}\text{ S cm}^{-1}$  at  $327\text{ K}$ . Upon further warming, it increases over two orders of magnitude to  $3.39 \times 10^{-7}\text{ S cm}^{-1}$  at  $350\text{ K}$ . Indeed, an anomaly in the conductivity is observed around  $330\text{ K}$ , which is close to the SCO found in the magnetic susceptibility data (Fig. S7†). In the absence of infinite stacking of the TTF in the structure, and the presence of integral charges without any mixed valency of the TTF or Fe, the crystals are insulating as observed. Thus, although the crystals are expected to be wide-band gap semiconductors, they show a maximum in electrical conductivity coinciding with the SCO transition.

Electric polarization arises from the polar displacement of anions and cations, lattice distortions, or metal-to-metal charge transfer (MMCT) and metal-to-ligand charge transfer (MLCT).<sup>21</sup> Intramolecular charge transfer induces a significant change in the electronic transition within the molecule and in the magnetic properties.<sup>22–24</sup> Therefore, charge transfer involving a change in polarization can be clearly detected by changes in the dielectric properties and magnetization measurements. To understand the origin of the dielectric anomalies, we performed DFT calculations on two phases (Table 3). At the b3lyp/6-31G\*\* level of theory, the calculated spin densities of the  $\text{Fe}^{\text{II}}$  centres are  $3.66$  for the quintet spin state and  $0.00$  for the singlet spin state (Table 3). The range of spin densities induced a change in the electric dipole moment from  $4.37\text{ D}$  for the quintet spin state to  $9.51\text{ D}$  for the singlet spin state, suggesting polarity conversion during thermally induced charge transfer. The results are quite clear about an SCO transition with spin-densities of  $3.7$  at  $350\text{ K}$  and  $0$  at  $123\text{ K}$ . In addition, the relative reduction of Müllen charge on the Fe centre of  $25\%$  substantiates some form of reorganisation. The increase of  $19\%$  in the dipole moment from HS to LS and the change in vector direction are the likely causes for the dielectric enhancement observed.

## Conclusion

In summary, by combining the redox-active TTF moiety which exhibits a relatively low redox potential, into a Schiff-base with a  $\text{N}_2\text{O}_2$  square coordination, a one-dimensional  $\text{Fe}^{\text{II}}$  polymer

was developed exhibiting unexpected coupling between spin-crossover and dielectricity enhancement. The reversible volume change of the  $\text{Fe}^{\text{II}}$  octahedron and bending of the TTF are coupled with the SCO. In light of the change in the TTF planarity with the oxidation state, we propose that it is potentially a concerted charge sharing between TTF and Fe centres. These results represent a new strategy towards the development of multifunctional molecular materials and provide impetus in the search for ferroelectricity coupled to spin-crossover.
