# Live cell screening to identify RNA-binding small molecule inhibitors of the pre-let-7–Lin28 RNA–protein interaction†

Sydney L. Rosenblum,<sup>a</sup> Dalia M. Soueid,<sup>b</sup> George Giambasu,<sup>c</sup> Steve Vander Roest,<sup>d</sup> Alexander Pasternak,<sup>e</sup> Erin F. DiMauro,<sup>e</sup> Vladimir Simov<sup>\*e</sup> and Amanda L. Garner<sup>\*ab</sup>

Dysregulation of the networking of RNA-binding proteins (RBPs) and RNAs drives many human diseases, including cancers, and the targeting of RNA–protein interactions (RPIs) has emerged as an exciting area of RNA-targeted drug discovery. Accordingly, methods that enable the discovery of cell-active small molecule modulators of RPIs are needed to propel this emerging field forward. Herein, we describe the application of live-cell assay technology, RNA interaction with protein-mediated complementation assay (RiPCA), for high-throughput screening to identify small molecule inhibitors of the pre-let-7d–Lin28A RPI. Utilizing a combination of RNA-biased small molecules and virtual screening hits, we discovered an RNA-binding small molecule that can disrupt the pre-let-7–Lin28 interaction demonstrating the potential of RiPCA for advancing RPI-targeted drug discovery.

## Introduction

It is well understood the paramount role that RNAs play in maintaining human health. No longer thought of as solely playing an intermediary role in the central dogma, RNAs have been demonstrated to perform multiple functions in the cell, including non-canonical tasks in the regulation of transcription, splicing, and translation, RNA function through RNA–RNA interactions, as well as catalysis. These functions are carried out by a pantheon of RNA molecules ranging in size and structure, from small ~22 nucleotide (nt) microRNAs (miRNAs) to >200 nt messenger RNAs (mRNAs), ribosomal RNAs (rRNAs) and long non-coding RNAs (lncRNAs) to highly structured RNA catalysts, or ribozymes. In combination with discoveries connecting aberrant RNA biology with human diseases, a new generation of RNA drug hunters has been

called to arms with the goal of unleashing small molecule chemistry for manipulating the cellular activities of RNAs.<sup>1</sup>

An important consideration in the field of RNA-targeted drug discovery is the extensive networking of RNAs with RNA-binding proteins (RBPs).<sup>2,3</sup> Indeed, RNAs are invariably bound to and often modified by RBPs.<sup>4–7</sup> These RBPs, in turn, regulate many aspects of coding and non-coding RNA biology, including RNA processing, nuclear export, function, localization, and stability.<sup>4–7</sup> In-line with the significance of these RBP functions, dysregulation of RNA–RBP networks has been linked to many human diseases, including cancers and neurodegeneration.<sup>8–11</sup> As such, targeting of RNA–protein interactions (RPIs) has emerged as a strategy for uncovering small molecules capable of modulating the function of cellular RNAs.<sup>12</sup>

To catalyze hit discovery efforts in this nascent field of RNA–protein interaction manipulation, our laboratory developed live-cell assay technology for the detection of RPIs, RNA interaction with protein-mediated complementation assay (RiPCA) (Fig. 1).<sup>13,14</sup> In RiPCA, cells are first engineered to stably express the small subunit of split NanoLuciferase (NanoLuc®) (SmBiT) fused to HaloTag® (HT) (SmBiT–HT).<sup>15,16</sup> These cells are then transiently co-transfected with a plasmid encoding an RBP fused to the large subunit of NanoLuc® (LgBiT) and an RNA substrate that is chemically modified to contain a chloroalkane HT ligand. Following uptake, the RNA becomes covalently labeled by SmBiT–HT to enable NanoLuc®-mediated chemiluminescence signal generation upon binding to the LgBiT-tagged RBP and

Fig. 1 RiPCA for the pre-let-7d-Lin28A RPI.

complementation of the SmBiT and LgBiT tags to reassemble functional NanoLuc®. Towards our goal of using RiPCA in high-throughput screening (HTS), we recently reported an optimized RiPCA protocol, RiPCA 2.0, which we subsequently used to detect a number of RBP interactions with precursor miRNAs (pre-miRNAs) and messenger RNAs (mRNAs).<sup>17,18</sup> Building upon these successful optimization studies, we were eager to demonstrate RiPCA's applicability for HTS. Herein we disclose our first RiPCA-based screening campaign focused on identifying small molecule inhibitors of the interaction of Lin28A, an RBP, with the pre-miRNA, pre-let-7d.

## Results and discussion

### Adaptation of RiPCA for HTS

In our previously reported assay development efforts, RiPCA was performed in 96-well format; however, for HTS, higher throughput was required. Using our previously developed RiPCA 2.0 assay for the pre-let-7d-Lin28A interaction (Fig. 1),<sup>17</sup> we miniaturized the assay to 384-well format to reduce reagent consumption and enable HTS (Fig. S1†). In addition to adaptation to liquid handling, several points of optimization were needed for miniaturization, including the number of cells per well, procedure for media removal prior to NanoLuc® substrate addition, and transfection scale-up (Fig. S2 and S3†). As an additional assay characterization step, we performed a pilot screen of 320 known drugs from the LOPAC library (Fig. S4†). From these optimization studies, which demonstrated that RiPCA could be performed in high throughput with suitable assay statistics (signal-to-background (S/B): 22–32; Z' factor: 0.3–0.68; Fig. S3 and S4†), we were encouraged that RiPCA would be amenable to HTS and subsequently employed this protocol for screening small molecule libraries.

### Screening campaign

Lin28 is a highly conserved oncofetal RBP that plays crucial roles in development, pluripotency, cell cycle, organismal and cellular growth, metabolism, and immunity.<sup>19–23</sup> The most

well-characterized RNA target of Lin28 is the tumor suppressor miRNA family, let-7, where Lin28 functions as a specific inhibitor of let-7 maturation by binding to a hairpin loop found within the pri- and pre-let-7 intermediates.<sup>24,25</sup> Although Lin28 is largely not expressed in adult somatic tissues (Fig. S5†) and restricted to embryonic development in mammals;<sup>23,26</sup> in cancer, it becomes transcriptionally activated resulting in the development of poorly differentiated tumors.<sup>19,20,23</sup> Loss of let-7 through Lin28 reactivation has been observed in at least 15% of all human cancers, including lung, breast, liver, esophageal, stomach, ovarian, prostate and colon cancers, and chronic lymphocytic leukemia.<sup>23,27–29</sup> Relatedly, reduced let-7 levels have been found to correlate with high grade tumors, poor patient prognosis, and drug resistance to existing therapies.<sup>20,23,28</sup> Dysregulation of the let-7/Lin28 pathway drives nearly all of the hallmarks of cancer, including regulation of cellular proliferation and metabolism, mediating cell death resistance, metastasis, angiogenesis and immune evasion, and promoting tumor-associated inflammation,<sup>23,30–32</sup> as the let-7 family plays an important role in down-regulating cellular oncogenes including *RAS* and its mutant isoforms, *MYCs* and *HMGA2* among others.<sup>33</sup> Accordingly, disruption of the let-7/Lin28 interaction has emerged as a promising anti-cancer therapeutic strategy,<sup>23</sup> and we were excited to deploy RiPCA to meet the goal of discovering drug-like and cell-active small molecule inhibitors of the pre-let-7d-Lin28A interaction.

As chemical libraries, we initially assembled a comprehensive set of 13.5 K compounds (*i.e.*, RNA Knowledge Based Set) that was designed to encompass various direct mechanisms of RNA function modulation, including published and proprietary RNA and RBP binders, as well as splicing modulators. To build the 13.5 K RNA KBS, the preliminary set of RNA tools subsequently underwent similarity (SIM) expansion by leveraging *in silico* tools that focused on shape similarity searches and established pharmacophore interactions with different types of RNA secondary structures, as well as synthesis of additional libraries and singleton

analogues for added chemical and structural diversity. In addition to the RNA KBS collection, we also created a Virtual Library set of 4.3 K compounds selected using an iterative virtual screening approach based on large-scale pharmacophore-based docking<sup>34–36</sup> and rescoring using Glide scoring functions.<sup>37–40</sup> Virtual screening was based on the Merck & Co., Inc., Rahway, NJ, USA compound collection against published structures of Lin28 with the pre-element of pre-let-7 and other small RNA fragments (PDB IDs: 5UDZ, 3TS0, 3TRZ, 3TS2)<sup>41,42</sup> and apo-form structures (PDB IDs: 4ALP, 4A4I, 4A75, 4A76, 3ULJ),<sup>43</sup> mainly focusing on the cold shock domain (CSD) and zinc knuckle domains (ZKD). Lastly, small molecule similarity screening based on previously reported let-7–Lin28 disrupters, TUTase inhibitors, and pre-miRNA hairpin binding molecules was used to complete the Virtual Library.<sup>44–52</sup>

Using our optimized HTS workflow (Fig. S1†), the combined collection of 17 797 small molecules (RNA KBS and Virtual Library) was screened at 10  $\mu\text{M}$  final concentration in

RiPCA (Fig. 2A; plate layout can be found in Fig. S6†). For each plate, a pre-miR-21 probe was used as a positive control and DMSO was used as a negative control. Throughout our screening campaign, the assay performed well with an average plate  $Z'$  factor of 0.37 and average S/B of 14.7. Our screening funnel can be found in Fig. 2B. Using a hit criterion of >55% inhibition, 992 compounds were identified as primary hits (5.6% hit rate); 758 hits came from the RNA KBS and 234 hits came from the Virtual Library. Because we anticipated that some hits may be false positives due to cytotoxicity, we subsequently performed a counterscreen using the CellTiter-Glo® (CTG) cell viability assay. By eliminating compounds that exhibited toxicity of >20% at 10  $\mu\text{M}$  in at least two of three replicates, 840 compounds (85% of the primary hits) were then taken on to triplicate analysis using RiPCA. Of the 840 compounds tested, 240 hits (28.6% of the primary hits) demonstrated inhibitory activity of >55% in two of the three replicates and were tested in dose-

Fig. 2 RiPCA HTS. (A) Campaign view of screening data. (B) HTS funnel and tabulated IC<sub>50</sub> values for the 3 most active hits in RiPCA and cat-ELCCA.

response assays. About one-third of tested molecules displayed dose-dependent inhibition, which was defined as  $pAC_{50}$  value  $>5$  (78 compounds; 7.9% of the primary hits).

### Hit validation

In addition to testing confirmed hits from our RiPCA primary screen, we also performed structure–activity relationship (SAR) studies in subsequent characterization assays through hit expansion to afford an additional 239 compounds with 2D and 3D structural similarity to the 78 hits. Compounds were first analyzed in the CTG assay (10  $\mu$ M in triplicate), and those that exhibited an average toxicity of  $>40\%$  were removed. The remaining 264 compounds were then analyzed for dose-dependent cellular inhibitory activity in RiPCA, as well as biochemical inhibitory activity using our laboratory's catalytic enzyme-linked click chemistry assay (cat-ELCCA) assay technology<sup>53</sup> that we previously used to screen against the pre-let-7–Lin28 RPI.<sup>44</sup> In cat-ELCCA, only 8.7% of tested compounds exhibited concentration-dependent inhibition. Representative data from RiPCA, cat-ELCCA, and CTG for the 3 most active compounds from RiPCA possessing a common pyrimido[4,5-*d*]pyridazine-5(6*H*)-ones pharmacophore can be found in Fig. S7.† Interestingly, all 3 of these hits were more active in RiPCA than in cat-ELCCA (Fig. 2B and S7†).

While it is uncommon, examples of molecules with greater potency in cells have been described, including several examples of small molecules targeting RNA–protein complexes.<sup>54</sup> Thus, to provide further evidence of inhibitory activity against the pre-let-7–Lin28 RPI, we determined how

these hits impacted the production of mature let-7 in cells. In brief, Lin28A-expressing T-47D breast cancer cells<sup>55</sup> were treated with compounds (5  $\mu$ M for 48 h), and let-7 levels were quantified from extracted RNA *via* qRT-PCR. In addition to let-7d, we also examined two other let-7s, let-7a-1 and let-7g. As shown in Fig. 3, excitingly, one of the hits, SID-415260 (structure in Fig. 4A), showed increased levels of two let-7s, let-7d and let-7a-1, which were previously shown to be regulated by Lin28A in this cell line.<sup>55</sup> Of note, treatment with higher compound concentrations was limited by toxicity in this cell line (data not shown). We additionally tested the inhibitory activity of SID-415260 in RiPCAs developed for pre-let-7a-1 and -7g.<sup>17</sup> Notably, RPI disruption was similar across the let-7s with measured  $IC_{50}$  values of 10.7  $\mu$ M, 7.4  $\mu$ M, and 12.5  $\mu$ M, respectively, for pre-let-7a, -7d, and -7g (Fig. 4B). As let-7g levels were not impacted by compound treatment in our qRT-PCR studies, this could point to additional levels of regulation of the maturation of this let-7 isoform in this cell line.

To provide further evidence that SID-415260 restored production of let-7, we tested the activity of this compound using the pmiRGLO dual-luciferase miRNA reporter assay.<sup>56</sup> NTERA-2 cells which express Lin28A and Lin28B were transiently transfected with a pmiRGLO reporter containing a let-7d target site in the 3' untranslated region of the firefly luciferase gene<sup>56,57</sup> and then treated with varying concentrations of compound for 48 h. Excitingly, in-line with our qRT-PCR results, we observed a decrease in luminescence signal produced by firefly luciferase over an empty vector control indicating enhanced let-7 activity (Fig. 4C).

Fig. 3 Measurement of mature let-7a, let-7d, and let-7g levels in T-47D cells following treatment with the 3 most active hits identified from RiPCA (5  $\mu$ M, 48 h). miRNA levels were normalized to miR-16.

**Fig. 4** Characterization of SID-415260. (A) Structure. (B) Inhibitory activity as measured in RiPCA for pre-let-7a, pre-let-7d, and pre-let-7g with Lin28A. (C) Cellular activity as measured using the pmIRGLO dual-luciferase assay with a let-7d reporter. (D) Tabulated binding kinetics and affinity measurements as measured *via* SPR.

SID-415260 belongs to a known class of pyrimido[4,5-*d*]pyridazine-5(6*H*)-ones reported as selective Wee1 kinase inhibitors, with the aminopyrimidine moiety making a key hinge interaction with Cys379 in the Wee1 ATP binding pocket.<sup>58</sup> The carbonyl group in the bicyclic pyrimido-pyridazinone has also been shown to engage with the Asn376 residue of the Wee1 gatekeeper region, further contributing to kinase activity and selectivity.<sup>58</sup> In our hands, SID-415260 inhibited Wee1 with an  $IC_{50}$  value of 35 nM across a panel of 264 kinases with an additional 18 kinases having measured  $IC_{50}$  values between 298 nM and 1  $\mu M$  (Table S4†). The promiscuity of this compound was anticipated based on the presence of the aminopyrimidine core which is a common hinge-binding motif found in many multi-kinase inhibitors,<sup>59,60</sup> including Wee1 kinase inhibitors of varying selectivity.<sup>61–64</sup> Of note, we confirmed that SID-415260 does not affect Lin28A phosphorylation (Fig. S8†), as this post-translational modification has been previously shown to impact Lin28A function.<sup>65</sup> Structurally, SID-415260 shows high 2D and 3D similarity relative to known RNA binders and modulators, including risdiplam, SMN-C3, and SMN-C5.<sup>66</sup> It contains a central bicyclic core with an aryl group at one end

and a basic piperazine cycloalkyl group at the other end of the molecule. Based on this structural similarity, as well as precedence for kinase inhibitors as RNA binding ligands,<sup>67–69</sup> it was included as part of the RNA KBS.

To decipher the mechanism of inhibitory action, we performed biophysical binding assays using surface plasmon resonance (SPR) spectroscopy. Biotinylated pre-let-7d and Lin28A were immobilized on high-sensitivity biotin-streptavidin sensors and SID-415260 was flowed over the immobilized biomolecules. The association ( $k_a$ ) and dissociation ( $k_d$ ) rates and binding constant ( $K_d$ ) were obtained by fitting to a 1:1 interaction model based on duplicate data sets. As shown in Fig. 4D, in-line with its prediction as a potential RNA-binding ligand, the compound was found to bind exclusively to the RNA with a  $K_d$  value of 10.2  $\mu M$  (sensorgrams can be found in Fig. S9†). To the best of our knowledge, this is the first reported direct pre-let-7-binding disruptor of the let-7/Lin28 interaction, as previously discovered compounds directly bind to Lin28 (ref. 44, 46–49 and 70) or function upstream at the level of Lin28 expression in cells.<sup>45,71</sup>

## Conclusions

As the field of small molecule RNA-targeted drug discovery expands, it necessitates the development of new technologies for enabling lead finding with functional cellular activity. Herein we disclose how RiPCA can be employed for HTS to discover small molecule inhibitors of cellular RPIs. Using the pre-let-7–Lin28 RPI as a model, we successfully miniaturized and automated RiPCA and screened biased libraries of small molecules to identify inhibitors of this cancer-relevant RPI. Excitingly, these efforts resulted in the uncovering of a Wee1 kinase inhibitor that binds to pre-let-7 with micromolar affinity and exhibits promising bioactivity in Lin28-expressing cancer cell lines. Our results demonstrate how RiPCA can be used to identify drug-like hits for targeting RPIs and future work will focus on optimizing affinity and specificity for pre-let-7 and applying this technology to additional RNA/RPI systems of relevance to human health and disease.
