Front.*, 2024, **11**, 3889Construction of a novel nickel-based MOF with accessible oxygen sites for efficient CH<sub>4</sub>/N<sub>2</sub> separation†Feifei Zhang,<sup>a</sup> Yuhao Tang,<sup>a</sup> Zhiwei Zhao,<sup>a</sup> Mengyue Lu,<sup>a</sup> Xiaoqing Wang,<sup>a,b</sup> Jinping Li<sup>a,b</sup> and Jiangfeng Yang<sup>a,b</sup>

Enriching coal-bed methane to provide pure methane is promising and attractive. However, it is challenging due to the similar properties of CH<sub>4</sub> and N<sub>2</sub>. In this work, a novel nickel-based metal–organic framework (named TUTJ-201Ni) with a high density of accessible oxygen sites was synthesized for CH<sub>4</sub>/N<sub>2</sub> separation. From the structure, oxygen atoms from ligands and  $\mu_2$ -hydroxyl are densely distributed on the surface of rhombic channels. Gas adsorption measurements showed that TUTJ-201Ni exhibited high CH<sub>4</sub> uptake over N<sub>2</sub>. CH<sub>4</sub>/N<sub>2</sub> selectivity at 298 K and 1.0 bar was calculated to be 7.2. Modeling studies indicated that the pore centers surrounded with accessible oxygen atoms are the optimal bonding sites. The stronger adsorption affinity of CH<sub>4</sub> can be attributed to multiple hydrogen bonding. The exceptional CH<sub>4</sub>/N<sub>2</sub> separation performance of this material was further evaluated using breakthrough experiments.

## 1. Introduction

The shortages of traditional fossil fuels and growing environmental problems have increased the urgency for new clean energy with more environmental protection and higher calorific value. Natural gas, a fossil fuel composed mostly of methane (CH<sub>4</sub>), is regarded as a substitute for coal and petroleum fuels due to its abundance and cleanliness.<sup>1</sup> Currently, the consumption of natural gas has reached 22% of the global energy consumption.<sup>2–4</sup> As one of the major sources of unconventional natural gas, coal-bed methane (CBM)—mainly consisting of CH<sub>4</sub> and N<sub>2</sub>—is an excellent complement to conventional natural gas. Unfortunately, because of the low CH<sub>4</sub> content (typically  $\leq 30\%$ ) in CBM, it is difficult to use it directly.<sup>5</sup> In industry, cryogenic distillation is the primary method for separating CH<sub>4</sub> from N<sub>2</sub> based on the boiling point difference between these two gases (CH<sub>4</sub>: 112 K, N<sub>2</sub>: 77 K).<sup>6</sup> However, limited by the harsh operating conditions (low temperature and high pressure), this technology is considered uneconomical and energy-intensive for CH<sub>4</sub> enrichment from CBM.<sup>7</sup>

Adsorption-based processes are a promising alternative to separate gases, owing to their high energy efficiency and intrinsic economic feasibility.<sup>8,9</sup> However, CH<sub>4</sub>/N<sub>2</sub> separation is particularly difficult because of their similar kinetic diameters (CH<sub>4</sub>: 3.8 Å, N<sub>2</sub>: 3.6 Å) and comparable polarizability (CH<sub>4</sub>:  $26.0 \times 10^{-25}$  cm<sup>3</sup>, N<sub>2</sub>:  $17.6 \times 10^{-25}$  cm<sup>3</sup>).<sup>10,11</sup> Numerous traditional porous materials, including activated carbons, zeolites, and molecular sieves, have been developed for CH<sub>4</sub>/N<sub>2</sub> separation, but they suffer from low selectivity and/or poor capacity.<sup>12–15</sup> Therefore, the design of new adsorbents that combine a high CH<sub>4</sub> selectivity and capacity is urgent.

In the past decades, metal–organic frameworks (MOFs) have received attention and shown great promise for gas separation because of their structural diversity and high tunability.<sup>16–21</sup> Regarding the CH<sub>4</sub>/N<sub>2</sub> adsorption separation, many MOFs have been reported to fulfill this important task.<sup>22–27</sup> Among the diverse range of MOFs reported so far, materials containing accessible oxygen sites show high separation potential in CH<sub>4</sub>/N<sub>2</sub> separation especially beneficial for improving CH<sub>4</sub> selectivity. For example, Bao and colleagues reported the synthesis of a squarate-based MOF, Co<sub>3</sub>(C<sub>4</sub>O<sub>4</sub>)<sub>2</sub>(OH)<sub>2</sub>, benefiting from the high density of negative oxygen binding sites in the pore wall, this material exhibited a high adsorption selectivity (12.5) of CH<sub>4</sub> over N<sub>2</sub> at 298 K and 1.0 bar.<sup>28</sup> Similarly, Xia *et al.* reported an MOF named CAU-21-BPDC, which has a high CH<sub>4</sub>/N<sub>2</sub> selectivity of 11.9 because of the strong adsorption affinity between CH<sub>4</sub> molecules and  $\mu_2$ -oxygen atoms from metal clusters.<sup>29</sup> Finally, Liu *et al.* found that STAM-1 had high CH<sub>4</sub>/N<sub>2</sub> selectivity (11.5 at 298 K and 1.0 bar) due to the presence of a high density of negative oxygen

†Electronic supplementary information (ESI) available. CCDC 2345232 and 2345233. For ESI and crystallographic data in CIF or other electronic format see DOI: <https://doi.org/10.1039/d4qi01008f>

atoms.<sup>30</sup> Overall, these oxygen-rich MOFs exhibit excellent CH<sub>4</sub>/N<sub>2</sub> selectivity. To our knowledge, there are few studies of CH<sub>4</sub>/N<sub>2</sub> separation behavior of oxygen-rich MOFs reported in the literature. Therefore, there is an urgent need to put more effort into this aspect of MOF research.

In this study, we prepared an ultramicroporous MOF, TUTJ-201Ni, which features a high density of accessible oxygen sites on the pore wall. The CH<sub>4</sub> and N<sub>2</sub> adsorption properties of TUTJ-201Ni have been characterized by isotherms, heats of adsorption ( $Q_{st}$ ), and the ideal adsorbed solution theory (IAST) selectivity. Breakthrough experiments were performed to evaluate its CH<sub>4</sub>/N<sub>2</sub> separation performance under dynamic conditions. Moreover, theoretical calculations combined with *in situ* infrared (IR) spectra were performed to further decipher the separation mechanism.

## 2. Experimental section

### 2.1 Materials

Nickel nitrate hexahydrate (Ni(NO<sub>3</sub>)<sub>2</sub>·6H<sub>2</sub>O, 99%) and 3,3'-bipyridine-5,5'-dicarboxylic acid (H<sub>2</sub>L, 98%) were purchased from Jilin Chinese Academy of Sciences-Yanshen Technology Co., Ltd. Tetrafluoroboric acid (HBF<sub>4</sub>, 48%) was purchased from Shanghai Aladdin Biochemical Technology Co., Ltd. *N,N*-Dimethylacetamide (DMA, 99%) and acetone (CH<sub>3</sub>COCH<sub>3</sub>, 99%) were provided by Sinopharm Chemical Reagent Co., Ltd. The above reagents were used directly without further purification. The distilled water used in the experiment was made by our laboratory.

### 2.2 General methods

The crystallinity of the TUTJ-201Ni powder was tested using a Bruker D8 ADVANCE X-ray diffractometer. The test was conducted using Cu-K $\alpha$  ( $\lambda = 1.5418 \text{ \AA}$ ) radiation, and the working voltage and current were 40 kV and 40 mA, respectively. Scanning was performed over the  $2\theta$  range of 5°–40° at 5° min<sup>−1</sup>. Thermogravimetric analysis (TGA) of the samples was performed using a Netzsch STA 449 F5 (Germany) differential thermal analyzer at an airflow rate of 100 mL min<sup>−1</sup>. The temperature test range was 298–1073 K, and the heating rate was 10 K min<sup>−1</sup>. Scanning electron microscopy (SEM) was performed on a ZEISS Sigma 300 at an accelerating voltage of 5 kV and energy dispersive X-ray spectroscopy was carried out using a Smart EDX system equipped with X-ray mapping at an accelerating voltage of 15 kV. The IR spectra were measured using a Shimadzu FT-IR 8400s Fourier-transform (FT) IR spectrometer. X-ray photoelectron spectroscopy (XPS) was measured on a Thermo ESCALAB 250XI using a monochromatized Al K $\alpha$  X-ray source, in which all of the binding energies were calibrated with reference to the C 1s peak (284.8 eV). Before the test, the samples and KBr were dried in an oven at 353 K for 2 h. CH<sub>4</sub> and N<sub>2</sub> single-component gas adsorption isotherms were measured using an APSP 2460 analyzer. The nitrogen adsorption and desorption isotherms of the samples at 77 K were obtained using an APSP 2020 analyzer. The kinetic profiles for

N<sub>2</sub> and CH<sub>4</sub> adsorption were measured using an Intelligent Gravimetric Analyzer (IGA 001, Hiden, UK). The samples were activated at 423 K and  $1 \times 10^{-1}$  mbar for 5 h before testing.

### 2.3 Synthesis

**Synthesis of TUTJ-201Ni.** We placed 9.0 mL of DMA, 0.9 mL of H<sub>2</sub>O, and 0.1 mL of HBF<sub>4</sub> (48 wt%) in a 20 mL glass vial containing Ni(NO<sub>3</sub>)<sub>2</sub>·3H<sub>2</sub>O (90.0 mg, 0.37 mmol) and H<sub>2</sub>L (30.0 mg, 0.12 mmol). The vial was sealed and placed in an oven preheated to 353 K. The solvothermal reaction took place at this temperature for 24 h. The products were collected by suction filtration and washed several times with fresh DMA and acetone.

### 2.4 Rietveld refinement for TUTJ-201Ni

The crystal structure data used in the refinement process were derived from the reported TUTJ-201Co crystal structure. The refinement results of TUTJ-201Ni were obtained by the Rietveld method using TOPAS software (Table S2, CCDC 2345233†).

### 2.5 *In situ* IR spectroscopic analysis

*In situ* IR spectra of adsorbed CH<sub>4</sub> and N<sub>2</sub> were obtained using a Bruker V70 equipped with an MCT detector, stainless steel high-temperature *in situ* IR cell, and KBr window. The resolution of the IR spectrum was set to 4 cm<sup>−1</sup>. For the analysis, a certain amount of adsorbent powder was placed in the sample cup of the high-temperature reaction cell and the powder scraped flat. TUTJ-201Ni samples were activated at 423 K and  $1 \times 10^{-1}$  mbar for 5 h. During the activation process, the heating and cooling rates of the adsorbent were both 5 K min<sup>−1</sup>. After the adsorbent was cooled to the test temperature, the IR spectrum of the activated sample was recorded as the background spectrum. Then, the tested gas was passed into the test system, and the IR data were collected until the adsorbent was saturated.

### 2.6 Breakthrough tests

In this experiment, we obtained the breakthrough curves of TUTJ-201Ni when the mixed gas flow rate was 8–16 mL min<sup>−1</sup>. The prepared TUTJ-201Ni (1.2 g) particles were activated at 423 K and  $1 \times 10^{-1}$  mbar for 5 h and then placed in an adsorption column ( $\varnothing$  4.0 mm  $\times$  100 mm) in an environment free from water. Before starting the test, the adsorption column was flushed with He gas at a flow rate of 15 mL min<sup>−1</sup> and 373 K, and then the inlet gas was switched to the mixture to be tested at a total gas flow rate of 8–16 mL min<sup>−1</sup>. The spectra of the gas at the outlet of the adsorption column were recorded using an online mass spectrometer (HPR-20 EGA, Hiden, detection limit 0.01%) to obtain the final breakthrough curves.

## 3. Results and discussion

TUTJ-201Ni was prepared from the reaction of 3,3'-bipyridine-5,5'-dicarboxylic acid and nickel nitrate hexahydrate in a

**Scheme 1** Structural description of TUTJ-201Ni. (a) Framework of TUTJ-201Ni formed by nickel atoms and 3,3'-bipyridine-5,5'-dicarboxylic acid ligand. (b) Local coordination environments of the organic ligand and metal centers. (c) Pore aperture and pore chemistry of TUTJ-201Ni. (d) Crystal structure of guest-free TUTJ-201Ni, showing one-dimensional channels. Color code: C, gray; H, white; O, red; Ni, indigo; N, blue.

mixture of water and DMF at 353 K for 24 h (Scheme 1). The structure of this MOF was accurately analyzed through Rietveld refinement using TOPAS software (CCDC: 2345233†) (Fig. 1a). Like TUTJ-201Co (Table S1†), TUTJ-201Ni crystallizes in the monoclinic space group *Pbcn* (Table S2†) and possesses the formula  $C_{24}H_{12}Ni_2N_4O_9$ . As described in Scheme 1, the framework is formed from hydroxide groups bridging regular octahedra of nickel atoms and organic linkers. Each nickel metal center exhibits an octahedral coordination environment through connection with four oxygen atoms and two nitrogen atoms, where three oxygen atoms and two nitrogen atoms are from five different organic linkers whereas the remaining oxygen atom comes from the bridging hydroxide group. TUTJ-201Ni shows rhombic-shaped one-dimensional channels of approximately 6.2 Å along the crystallographic *b*-axis, and the pore wall was decorated by multiple oxygen sites.

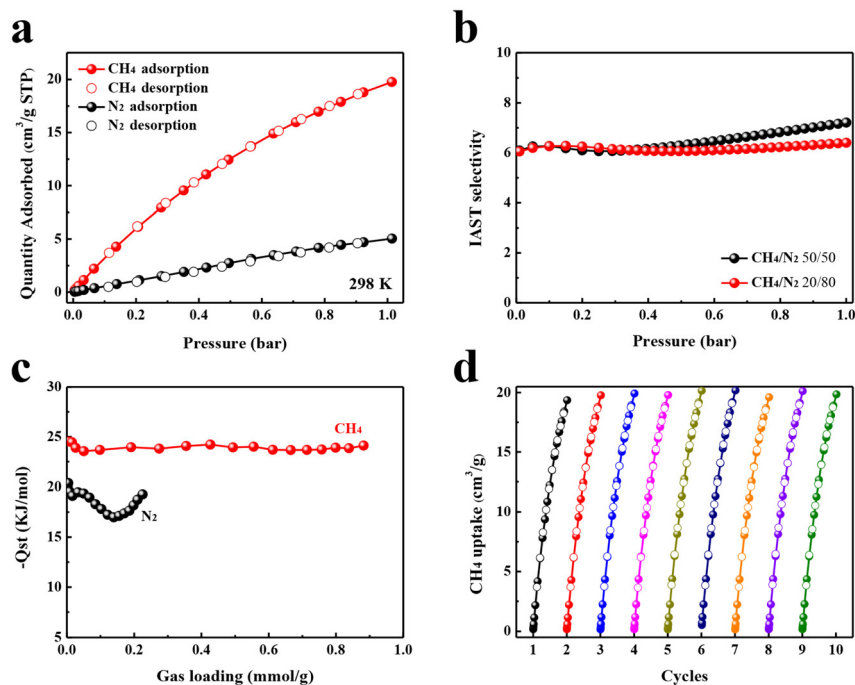

As shown in Fig. 1a, the structure of TUTJ-201Ni was identified by Le Bail analysis, which shows good reliability factors ( $R_p = 0.0612$  and  $R_{wp} = 0.0468$ ), indicating that TUTJ-201Ni has an identical framework to TUTJ-201Co. As shown in Fig. 1b, SEM/EDX mapping shows that TUTJ-201Ni had spindle-shape morphology and the O elements were uniformly distributed on the crystal surface. The content of O element was further verified using XPS (Fig. 1c), one peak was detected at 530.9 eV, revealing the presence of  $O^{2-}$  ions in the framework, and the atomic ratio for O/Ni reached up to 4.85 (Table S4†). To probe the porous nature of TUTJ-201Ni, 77 K  $N_2$  adsorption experiments were conducted (Fig. 1d). The resulting  $N_2$  adsorption isotherms display a typical type-I behavior with a sharp

increase at low relative pressures, validating its inherent microporous structures. The calculated Brunauer–Emmett–Teller (BET) surface area and pore volume were  $432 \text{ cm}^2 \text{ g}^{-1}$  and  $0.14 \text{ cm}^3 \text{ g}^{-1}$ , respectively. The pore size distribution was further analyzed using the standard non-local density functional theory model (Fig. 1e). The observed pore size was mainly concentrated at  $0.59 \text{ Å}$ , which is in line with the theoretical value. We also investigated the thermal stability of TUTJ-201Ni using TGA and variable-temperature PXRD experiments. As shown in Fig. 1f and S6, S7,† the results show that the framework is thermally stable up to  $300^\circ\text{C}$ . The exceptional stability of TUTJ-201Ni could be attributed to the robust Ni–N bonds in the framework.

Single-component isotherms of  $CH_4$  and  $N_2$  were measured at different temperatures up to 1.0 bar (Fig. S8†). As shown in Fig. 2a, TUTJ-201Ni shows extremely steep  $CH_4$  adsorption isotherms at low pressure, whereas  $N_2$  exhibits an almost linearly increasing trend. At 1.0 bar, the uptake of  $CH_4$  reaches  $19.8 \text{ cm}^3 \text{ g}^{-1}$ , which is 3.9 times higher than that of  $N_2$  ( $5.0 \text{ cm}^3 \text{ g}^{-1}$ ). This significant difference in the adsorbed amount indicates that TUTJ-201Ni has a stronger affinity for  $CH_4$  over  $N_2$ . To evaluate the  $CH_4$  uptake of TUTJ-201Ni, its  $CH_4$  uptake was compared with that of other adsorbents. As shown in Table S5,†  $CH_4$  uptake is higher than that of  $Co_3(C_4O_4)_2(OH)_2$  ( $8.9 \text{ cm}^3 \text{ g}^{-1}$ ),<sup>28</sup> STAM-1 ( $14.2 \text{ cm}^3 \text{ g}^{-1}$ )<sup>30</sup> and  $Co_3(HCOO)_6$  ( $11.0 \text{ cm}^3 \text{ g}^{-1}$ ),<sup>31</sup> comparable to the other state-of-the-art porous materials such as SBMOF-1 ( $20.6 \text{ cm}^3 \text{ g}^{-1}$ ),<sup>27</sup> CAU-21-BPDC ( $22.2 \text{ cm}^3 \text{ g}^{-1}$ )<sup>29</sup> and  $Cu(INA)_2$  ( $18.6 \text{ cm}^3 \text{ g}^{-1}$ ).<sup>32</sup> To estimate further the separation performance of TUTJ-201Ni,

**Fig. 1** (a) Rietveld-refined XRD pattern obtained for TUTJ-201Ni ( $R_{wp} = 6.12\%$ ,  $R_p = 4.68\%$ ,  $GOF = 2.01$ ,  $a = c = 3.06 \text{ \AA}$ ,  $b = 16.57 \text{ \AA}$ ,  $\alpha = 90^\circ$ ,  $\beta = 90^\circ$ ,  $\gamma = 120^\circ$ ). The black lines and red circles represent the experimental data and calculated values, respectively. (b) SEM/EDX mapping of TUTJ-201Ni. (c) XPS spectrum obtained for TUTJ-201Ni: O 1s spectra. (d)  $N_2$  sorption isotherms obtained for TUTJ-201Ni at 77 K. (e) Calculated pore size distribution of TUTJ-201Ni. (f) TGA curve obtained for TUTJ-201Ni.

**Fig. 2** (a)  $CH_4$  and  $N_2$  adsorption isotherms measured for TUTJ-201Ni at 298 K. (b) IAST selectivity of  $CH_4/N_2$ . (c)  $Q_{st}$  curves calculated for  $CH_4$  and  $N_2$  sorption. (d) The recycling performance of TUTJ-201Ni.

the CH<sub>4</sub>/N<sub>2</sub> selectivities were calculated using IAST. As displayed in Fig. 2b, the calculated CH<sub>4</sub>/N<sub>2</sub> selectivity for the corresponding binary equimolar mixture in TUTJ-201Ni is up to 7.2 at 298 K and 1.0 bar. This value is comparable to a series of reported materials, including CAU-10 (7.2),<sup>33</sup> ZIF-94 (7.4)<sup>34</sup> and MOF-891 (7.8).<sup>35</sup>  $Q_{st}$  of CH<sub>4</sub> and N<sub>2</sub> were further calculated using the dual-site Langmuir–Freundlich model to evaluate the interactions between the adsorbents and gases (Fig. 2c). The  $Q_{st}$  values of CH<sub>4</sub> are in the range of 24.5–24.1 kJ mol<sup>−1</sup>, which is notably higher than that of N<sub>2</sub> (20.2–19.2 kJ mol<sup>−1</sup>) in the whole range. At zero loading, the  $Q_{st}$  of CH<sub>4</sub> for TUTJ-201Ni is 24.5 kJ mol<sup>−1</sup>, which is significantly higher than that of most high-performance MOFs,<sup>27,29,32</sup> implying a strong binding interaction between CH<sub>4</sub> and the framework. Interestingly, we found that upon increasing the CH<sub>4</sub> loading, the  $Q_{st}$  value were smooth lines with almost unchanged values. This implies the energetic homogeneity of the TUTJ-201Ni surface, and a similar phenomenon was also observed in [Co<sub>3</sub>(C<sub>4</sub>O<sub>4</sub>)<sub>2</sub>(OH)<sub>2</sub>].<sup>28</sup> Furthermore, the nine cycles of CH<sub>4</sub> adsorption/desorption tests indicate that TUTJ-201Ni has excellent reproducibility (Fig. 2d), the successive adsorption/desorption cycles were measured at 298 K and a testing pressure up to 1.0 bar without a regeneration process.

For insight into the adsorption mechanism of CH<sub>4</sub> and N<sub>2</sub> in TUTJ-201Ni at the molecular level, we carried out grand canonical Monte Carlo (GCMC) simulations and density functional theory (DFT) calculations to illustrate the interactions between the framework and gases. As shown in Fig. 3a and b, the CH<sub>4</sub> and N<sub>2</sub> gas molecules both appear around the center of the rhombic pore, indicating pore centers are the most energetically favorable binding sites for both adsorbates. The

density of CH<sub>4</sub> adsorbed in TUTJ-201Ni is obviously higher than that of N<sub>2</sub>, which is in full agreement with their adsorption capacities. DFT calculations were thereafter carried out to directly visualize the locations of CH<sub>4</sub>/N<sub>2</sub> within TUTJ-201Ni. As revealed in Fig. 3c, the CH<sub>4</sub> molecule is preferentially adsorbed at the center of the MOF pore, where it forms three C–H...O hydrogen-bonding interactions with the two nearby uncoordinated carboxylate oxygen atoms and one  $\mu_2$ -hydroxyl oxygen atom, with close interaction distances ranging from 3.25 to 3.67 Å. By contrast, the N<sub>2</sub> molecule is oriented parallel to the *c*-axis in the channels and interacts with the framework through weak van der Waals forces with N≡N...O distances of approximately 3.36 and 3.98 Å (Fig. 3d). Obviously, the average distance between a CH<sub>4</sub> molecule and the framework is shorter than that for N<sub>2</sub>, indicating a stronger adsorption affinity of TUTJ-201Ni for CH<sub>4</sub> over N<sub>2</sub>. The calculated binding energies for CH<sub>4</sub> and N<sub>2</sub> are respectively 28.6 and 23.0 kJ mol<sup>−1</sup>, which is in accordance with the experimental findings.

*In situ* IR spectroscopic measurements were carried out to probe further the interaction of CH<sub>4</sub> within TUTJ-201Ni. Fig. 4 presents the change of stretching bands upon CH<sub>4</sub> loading. Two distinct stretching bands at 1303 and 3014 cm<sup>−1</sup> are observed, which are attributed to the  $\delta$ (C–H) and  $\nu_s$ (C–H) stretching bands, respectively. This observation proved the strong interaction between CH<sub>4</sub> molecules and the framework.<sup>25</sup> With the adsorption of the CH<sub>4</sub> on TUTJ-201Ni, the intensity of the stretching band significantly increased. This may be attributed to the high gas adsorption capacity of this material.

To evaluate the feasibility of TUTJ-201Ni for a practical CH<sub>4</sub>/N<sub>2</sub> separation, experimental breakthrough studies were

**Fig. 3** (a and b) Density distributions of CH<sub>4</sub> and N<sub>2</sub> within TUTJ-201Ni at 298 K, the red dashed circles indicate the favorable adsorption sites. (c and d) The DFT-optimized adsorption configurations of CH<sub>4</sub> and N<sub>2</sub> in TUTJ-201Ni.

Fig. 4 *In situ* IR spectra of CH<sub>4</sub> adsorbed on TUTJ-201Ni with different CH<sub>4</sub> dosing durations at 298 K.

conducted. As depicted in Fig. 5a, for 50/50 CH<sub>4</sub>/N<sub>2</sub> mixtures, N<sub>2</sub> first penetrated the adsorption bed at 1.5 min g<sup>-1</sup>, and after long periods, CH<sub>4</sub> was detected. The difference between the breakthrough times of the two gases reached 1.4 min g<sup>-1</sup>, which offers a large operating window for CH<sub>4</sub> release during pressure-swing adsorption processes. Furthermore, eight continuous cycling breakthrough experiments were performed on TUTJ-201Ni. No appreciable change in retention time was observed, proving its good recyclability for CH<sub>4</sub>/N<sub>2</sub> separation.

After each cycle, TUTJ-201Ni in the column can be readily regenerated within 30 min by He purge. We also investigated the concentration capacity of this material for low concentrations of CH<sub>4</sub> (Fig. 5b); when the CH<sub>4</sub>/N<sub>2</sub> ratio was adjusted to 10/90, TUTJ-201Ni still had a good separation effect. Fig. 5c and d show the breakthrough curves under different temperatures or with different flow rates. The results demonstrated that TUTJ-201Ni effectively separates CH<sub>4</sub> from the mixture under various practical separation scenarios.

Fig. 5 (a) Experimental breakthrough cycles for CH<sub>4</sub>/N<sub>2</sub> (50/50) separation on TUTJ-201Ni at 298 K and 1.0 bar. (b) Experimental breakthrough curves obtained for 50/50, 20/80, and 10/90 mixtures under a flow rate of 8 mL min<sup>-1</sup> at 298 K and 1.0 bar. (c) Breakthrough curves of TUTJ-201Ni for CH<sub>4</sub>/N<sub>2</sub> (50/50) mixtures at 298 K with the flow rate of 8, 12, and 16 mL min<sup>-1</sup>. (d) Experimental breakthrough curves obtained for TUTJ-201Ni during the separation of CH<sub>4</sub>/N<sub>2</sub> (50/50) at 1.0 bar and different temperatures.

## 4. Conclusion

In this study, we developed a novel Ni-based MOF, TUTJ-201Ni, with a high density of accessible oxygen sites for efficient CH<sub>4</sub>/N<sub>2</sub> separation. Because of the strong affinity of the CH<sub>4</sub> molecule within the framework, the CH<sub>4</sub>/N<sub>2</sub> selectivity of TUTJ-201Ni reaches up to 7.2, along with satisfactory CH<sub>4</sub> uptake (19.8 cm<sup>3</sup> g<sup>-1</sup>). GCMC simulations combining DFT calculations indicated that two uncoordinated carboxylate oxygen atoms and one  $\mu_2$ -hydroxyl oxygen atom in the pore wall could selectively combine with the H atoms of the CH<sub>4</sub> molecule *via* multiple C-H...O interactions, thereby affording strong CH<sub>4</sub> adsorption affinity. Breakthrough experiments confirmed that TUTJ-201Ni can separate CH<sub>4</sub>/N<sub>2</sub> mixtures under various separation scenarios. Our work not only provides a potential candidate for the separation of CH<sub>4</sub>/N<sub>2</sub> in practical industries but also demonstrates the significance of designing oxygen sites for this challenging task.
