# Switching between TADF and RTP: anion-regulated photoluminescence in organic salts and co-crystals†

Zhen Xu,<sup>id</sup><sup>a</sup> Duane Hean,<sup>id</sup><sup>a</sup> Clàudia Climent,<sup>id</sup><sup>b</sup> David Casanova<sup>id</sup><sup>\*cd</sup> and Michael O. Wolf<sup>id</sup><sup>\*a</sup>

Thermally activated delayed fluorescence (TADF) and room temperature phosphorescence (RTP) are two photophysical phenomena which utilize triplet excitons. In this work, we demonstrate how variation of the anion in organic salts with carbazole and phenothiazine-5,5-dioxide donors and pyridinium and quinolinium acceptors may be used to switch between TADF and RTP. These compounds adopt similar molecular structures and packing modes with different anions and exhibit different types of photophysical behavior due to the electronic effects of the anions. With bromide anions, the salts exhibit TADF with some RTP. These compounds show fast reverse intersystem crossing and a short delayed lifetime, which is key to application in efficient and robust OLEDs. With  $\text{BF}_4^-$  and  $\text{PF}_6^-$  anions, RTP with long-lived lifetimes and afterglow are observed by eye. This behavior can be utilized for data encryption and anti-counterfeiting applications. Emission wavelengths and lifetimes are also anion-dependent. These results open up an avenue for developing novel luminescent materials through anion tuning and present a molecular model to understand the interplay of RTP and TADF.

## Introduction

Organic luminescent materials that can effectively harvest triplet excitons are advantageous for numerous applications including organic light-emitting diode (OLED) displays, chemical sensors and as bioimaging agents.<sup>1–4</sup> The two main strategies to utilize triplet excitons are thermally activated delayed fluorescence (TADF) and room temperature phosphorescence (RTP). TADF involves emission from a singlet excited state with a delayed component, and many highly efficient OLED devices have been fabricated using TADF emitters.<sup>5,6</sup> In contrast, RTP arises from direct emission from the triplet excited state, and due to its ultralong lifetime, researchers have utilized the ‘afterglow’ feature in bioimaging, sensing, anti-counterfeiting and data encryption materials.<sup>7–10</sup>

It is important to understand the relationship between TADF and RTP both to develop novel multifunctional luminescent materials and to shed light on triplet processes in organic molecules from a fundamental perspective.<sup>11,12</sup> Many efforts have been made towards bridging these two phenomena. Through structural modifications, the singlet-triplet energy gap  $\Delta E_{ST}$  or the triplet chromophore stacking can be tuned in favor of either TADF or RTP.<sup>13–17</sup> Crystal polymorphs of the same molecule, on the other hand, may also exhibit different behaviors in triplet states.<sup>18,19</sup> These strategies, however, often involve extensive synthesis or complex crystal engineering, which makes the process of understanding TADF vs. RTP difficult. Furthermore, it is also a challenge to study the electronic effects alone without altering the packing mode in the crystalline state at the same time.

In some cases, organic compounds have been found to exhibit both TADF and RTP concurrently.<sup>15,17,19–21</sup> It has been reported that a hidden RTP state of a TADF molecule can potentially serve as a ‘springboard’ for long-lived triplet excitons and facilitate reverse intersystem crossing (RISC). This finding further demonstrates the importance and urgency of developing novel and facile strategies with versatile molecular models to understand the interplay of TADF and RTP.

Variation of the corresponding anions can be utilized to tune the photoluminescence properties of organic cations. Inorganic anions such as  $\text{PF}_6^-$  have been shown to enhance

**Scheme 1** Chemical structures of carbazole-containing pyridinium (**Py**) and quinolinium (**Qui**) compounds.

solid-state fluorescence in 1,2,3,4-tetraphenylloxazolium (**TPO**) molecular systems, which feature aggregation-induced emission (AIE),<sup>22,23</sup> while phosphorescence efficiency can be improved by pairing anions such as bromide and iodide with the cations due to the heavy atom effect.<sup>20</sup> In carbazole-containing phosphonium salts, the phosphorescent triplet state becomes accessible with halide anions, thereby reducing fluorescence and enhancing phosphorescence.<sup>24,25</sup> Even though success has been found in achieving phosphorescence in organic crystals with inorganic anions such as  $\text{BF}_4^-$ ,<sup>26</sup> the utilization of anions to fine-tune RTP or TADF remains relatively unexplored.

We elected to use carbazole as the donor and N-heterocyclic cations including pyridinium and quinolinium<sup>27</sup> as acceptors for

RTP. Herein, we report the design, synthesis and characterization of a series of non-conjugated carbazole species containing pyridinium and quinolinium acceptor groups with different anions (Scheme 1). By varying the anion, switching between RTP and TADF can be realized. The origin of the differences in the photophysical properties of these compounds and the role of anions is rationalized by means of density functional theory (DFT) and time-dependent DFT (TDDFT) calculations, providing a perspective into anion regulated photoluminescence.

## Synthesis and structures

Compound **Py-Br** was synthesized *via* direct alkylation of pyridine by 9-(4-bromobutyl)-9*H*-carbazole. This reaction occurs under neat conditions, negating the need for any solvent. Further anion exchange by adding a saturated aqueous solution of  $\text{NH}_4\text{BF}_4$  or  $\text{NH}_4\text{PF}_6$  to an acetone solution of **Py-Br** resulted in precipitation of the desired product **Py-BF<sub>4</sub>** and **Py-PF<sub>6</sub>**, which can then be isolated by filtration. Species containing the chloride and iodide counter anions (**Py-Cl** and **Py-I**) were obtained through reaction of **Py-PF<sub>6</sub>** with either tetrabutylammonium chloride or iodide ( $\text{NBu}_4\text{Cl}$  or  $\text{NBu}_4\text{I}$ ). **Qui-Br** and **Qui-BF<sub>4</sub>** were synthesized in a similar fashion. These syntheses do not require any column chromatography, with purification occurring *via* a simple solvent wash and recrystallization, resulting in high product yields. All compounds were characterized using NMR spectroscopy and high-resolution mass

**Fig. 1** Different crystal views of the intermolecular packing of **Py-Br** (a and b) and **Qui-Br** (e and f). (c and d) Molecular  $\pi^+\cdots\pi^+$  and Br-H interactions in **Py-Br**. (g) Molecular  $\pi^+\cdots\pi^+$  and  $\pi^+\cdots\pi^+$  interactions in **Qui-Br**.

spectrometry.  $^1\text{H}$  and  $^{13}\text{C}$  signals were assigned using COSY, HSQC and HMBC experiments.

Solid-state structures of all the compounds were obtained by single crystal X-ray diffraction. Suitable single crystals of the species were grown by slow evaporation of acetone solutions (**Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>** and **Qui-Br**) or  $\text{CH}_2\text{Cl}_2$  solutions (**Py-Cl**, **Py-Br**, **Py-I** and **Qui-BF<sub>4</sub>**). Pyridinium salt (**Py**) crystals belong to the *Pbca* space group with similar unit cell dimensions whereas the two quinolinium salts adopted the *P2<sub>1</sub>/n* space group. Similar molecular geometries with the anions positioned close to the cationic centers are found for the pyridinium (**Py**) and quinolinium (**Qui**) compounds, demonstrating that the specific anion present does not affect the individual molecular structures of the cations. Compounds with  $\text{Cl}^-$  and  $\text{Br}^-$  anions exhibit hydrated structures, due to the hydrogen-bonding tendency of these anions and the smaller anionic size.

The intermolecular interactions in these salts have also been carefully examined by analyzing the packing diagrams (Fig. 1). These interactions are key to understanding the solid-state photoluminescence properties (see below). The pyridinium compounds all adopt similar packing modes in which two pyridinium rings are parallel in the center of the unit cell. The distances between the two pyridinium rings ranges between 3.468 Å in **Py-I** and 3.768 Å in **Py-PF<sub>6</sub>**, indicative of strong  $\pi^+-\pi^+$  interactions in **Py-I**. **Py-PF<sub>6</sub>** has the largest anion, which leads to the weakest  $\pi^+-\pi^+$  interaction among the compounds.<sup>28</sup> Three other types of intermolecular interactions including  $\text{CH}\cdots\text{N}$ ,  $\text{CH}\cdots\pi^+$  and  $\text{CH}\cdots\text{CH}$  are also observed in the structures. The hydrogen atoms on either the pyridinium ring or the carbazole ring can interact with another carbazole  $\pi$ -conjugated ring, with distances ranging from 2.418 to 2.900 Å. The hydrogen atom on the carbazole moiety can also have short contacts with the nitrogen atom on the carbazole ring to give  $\text{CH}\cdots\text{N}$  interactions.  $\text{CH}\cdots\pi^+$  and  $\text{CH}\cdots\text{CH}$  interactions are also observed. It is worth noting that halogen-containing compounds such as **Py-Br**, **Py-Cl** and **Py-I**, exhibit halogen-hydrogen interactions with pyridinium, carbazole and with hydrogens at  $\text{sp}^3$  hybridized carbon atoms.

The solid-state structures of the quinolinium salts **Qui-Br** and **Qui-BF<sub>4</sub>** also contain abundant short contacts. Interestingly, they both show strong  $\pi-\pi^+$  and  $\pi^+-\pi^+$  interactions. One quinolinium ring aligns in parallel with a carbazole unit and another quinolinium ring to form H-aggregates. The  $\pi-\pi^+$  distances in **Qui-Br** and **Qui-BF<sub>4</sub>** are 3.439 and 3.355 Å,

respectively. Similarly,  $\text{CH}\cdots\pi$  interactions are also present in the crystal structures between the quinolinium hydrogens and carbazoles. However, there are no  $\text{CH}\cdots\pi$  interaction between two carbazole moieties. In **Qui-Br**,  $\text{Br}\cdots\text{H}$  halogen interactions also exist and are measured as  $\sim 2.9$  Å.

## Photophysics

The absorption and photoluminescence (PL) spectra of all compounds in  $\text{CH}_2\text{Cl}_2$  solutions are shown in Fig. S2 (ESI<sup>†</sup>). The absorption spectra of the pyridinium compounds appear virtually identical to those of the related 9-alkyl carbazole compounds, reported by Xue and co-workers.<sup>29</sup> Compound **Py-I**, on the other hand, exhibits a broad feature between 360 nm and 420 nm, which is attributed to charge transfer between the pyridinium cation and the iodide anion. Electronic structure calculations confirm the presence of low-lying CT excitations of iodide 5p electrons to the pyridinium moiety (Fig. S27, ESI<sup>†</sup>). On the other hand, CT transitions are not observed with the other counter anions (Tables S3 and S4, ESI<sup>†</sup>). Quinolinium compounds (**Qui-Br** and **Qui-BF<sub>4</sub>**) exhibit slightly different absorption behavior between 300 nm to 350 nm, which result from contributions of the quinolinium moiety, as computationally characterized (Table S7, ESI<sup>†</sup>). All the species show structured emission peaks at 350 nm and 370 nm. These are attributed to the locally excited state on carbazole, although emission from a state localized on quinolinium cannot be discounted as the excitation energies of the two local states are rather close to each other (Table S7 and Fig. S30, ESI<sup>†</sup>).<sup>30</sup> The localized nature of the low-lying excited singlets on either of the two moieties indicates that there is no strong interaction between the cationic heterocyclic units and carbazole in dilute  $\text{CH}_2\text{Cl}_2$  solutions. The photoluminescence quantum yields (PLQYs) in  $\text{CH}_2\text{Cl}_2$  solution are extremely low ( $< 0.1\%$ ), consistent with the PLQYs reported for similar compounds in the literature.<sup>28</sup>

Powder X-ray diffraction (pXRD) patterns of **Py-Br**, **Py-Cl**, **Qui-Br** and **Qui-BF<sub>4</sub>** were also collected in order to determine the solid-state structures in the bulk phase (Fig. S1, ESI<sup>†</sup>). The experimental patterns match the simulated patterns generated from the single crystal structures well, indicating that the bulk powder samples of these compounds pack the same as in the single crystals. The single crystals of **Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>** and **Py-I** were used for photophysical measurements.

Table 1 Summary of solid-state photophysical data

<sup>a</sup>  $\lambda_{\text{ex}} = 359$  nm. <sup>b</sup> Relative amplitudes in parenthesis.

The solid-state photoluminescence of the pyridinium and quinolinium compounds (**Py** and **Qui**) exhibit entirely different behavior from solution. The luminescence intensity increases dramatically relative to in solution (Table 1) due to aggregation-induced emission (AIE).<sup>28</sup> For the pyridinium compounds, **Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>** and **Py-Cl** display similar PLQYs of  $\sim 0.6$ , while **Py-Br** is slightly less emissive, possibly due to heavy-atom quenching<sup>31</sup> triggered by the short contact between carbazole and the Br atom. The quinolinium compounds exhibit much weaker photoluminescence of 0.15 and 0.17 for **Qui-Br** and **Qui-BF<sub>4</sub>**, respectively. The strong  $\pi$ - $\pi^+$  stacking may be the cause of the quenching.<sup>32</sup> In accordance with this, electronic structure calculations show sizeable  $\pi$ - $\pi^+$  overlaps around the Fermi level favored by the CBZ-**Qui**-**Qui**-CBZ coplanar arrangement in the crystal (Fig. 2), stabilizing spin singlet excitations with strong CT character between stacked carbazole and quinolinium cations (Table S7, ESI<sup>†</sup>). Moreover, the lowest singlet-singlet excitations have weak transition dipole moments, which may be related to the weak photoluminescence. These compounds are categorized into three types based on their photo-physical behavior: those exhibiting thermally activated delayed fluorescence (TADF), room temperature phosphorescence (RTP) or low temperature phosphorescence (LTP).

The steady-state emission spectrum of the crystalline powder of **Py-Br** shows a broad featureless peak with a maximum at 488 nm, red shifted compared to the emission in solution. This is attributed to through-space interactions between pyridinium and carbazole.<sup>28</sup> The fluorescence decay profile measured by time-correlated single photon counting consists of two components, prompt fluorescence with a lifetime of 43 ns and a 354 ns delayed emission (Fig. 3(b)). The amplitudes of these two components are 70% and 30%, respectively.

Time-resolved photoluminescence spectroscopy at room temperature was carried out to understand the emission features at different time ranges. The time-resolved spectra in the microsecond range are identical to the steady-state spectra, indicating that the delayed emission originates from the same singlet excited state as the prompt fluorescence. However, with a delay time of 1 ms, the luminescence spectrum of **Py-Br** shows a red-shift to 515 nm, indicative of a second radiative excited state (Fig. 3(a)). The photoluminescence decay of this long-lived component gives a long lifetime of 58 ms with a yellow afterglow, which is attributed to RTP from the lowest triplet state localized on the carbazole fragment (Table S4, ESI<sup>†</sup>). Therefore,

Fig. 2 Main orbital contribution (HOMO-2  $\rightarrow$  LUMO) to the lowest excited singlet computed for the **Qui-BF<sub>4</sub>** crystal tetramer at the  $\omega$ B97X-D/6-31+G(d) computational level.

Fig. 3 (a) Steady-state and time-resolved spectra of crystalline **Py-Br** at room temperature under air. Inset: Photograph of **Py-Br** after UV excitation is removed. (b) Fluorescence and (c) phosphorescence decay curve of crystalline **Py-Br** at room temperature under air.

**Py-Br** displays prompt fluorescence, delayed fluorescence (DF) and RTP concurrently.

The origin of this delayed feature was further investigated by probing the emission of **Py-Br** as a function of temperature. When cooled to 77 K, the 1 ms delayed spectrum shows well-structured emission with a lifetime of 544 ms that originates from the locally excited triplet states of carbazole (Fig. 4).<sup>30</sup>

Fig. 4 (a) Steady-state and time-resolved photoluminescence spectra of crystalline **Py-Br** at 77 K. (b) Phosphorescence decay curve of crystalline **Py-Br** at 77 K. (c) Arrhenius plot of  $\ln(K_{\text{RISC}})$  versus temperature to calculate  $\Delta E_{\text{ST}}$ .

Such long-lived phosphorescence gives an afterglow that lasts for seconds after the UV excitation source is removed. Since the delayed spectrum overlaps significantly with the prompt spectrum, it is difficult to extrapolate  $\Delta E_{ST}$  from these measurements. Therefore, the fluorescence lifetimes were measured from 260 K to 310 K for every 10 K since  $k_{RISC}$  is proportional to  $\exp(\Delta E_{ST}/k_B T)$ , where  $k_B$  is the Boltzmann constant and  $T$  is the temperature.<sup>33</sup> The resultant linear plot ( $R^2 = 0.976$ ) further proves the ‘thermally activated’ feature of the delayed emission and the fitted  $\Delta E_{ST}$  is 178 meV, consistent with TDDFT computed gap of 0.15–0.17 eV between singlet and triplet states localized on carbazole (Tables S4 and S5, ESI†). The RTP lifetime is considerably longer than the DF, suggesting that they arise from two different triplets. This interpretation is in line with our calculations (Tables S4 and S5, ESI†), which locate a triplet state energetically close to the lowest singlet (related to DF) different than the lowest triplet (related to RTP). Alternatively, the DF could emerge from triplet–triplet annihilation, but this possibility can be eliminated since delayed emission intensity increases linearly with the excitation power (Fig. S4, ESI†). We therefore conclude that **Py-Br** is a TADF emitter that also exhibits RTP character.

Replacing the pyridinium unit with a quinolinium unit results in an increase in  $\pi$ - $\pi^+$  and  $\pi^+$ - $\pi^+$  interactions, as characterized by the orbital mixing between different units (Fig. S29, ESI†), and the **Qui-Br** crystalline powder is yellow in colour. Similar to **Py-Br**, **Qui-Br** also displays TADF (Fig. S3, ESI†). The steady-state photoluminescence is significantly red-shifted compared to **Py-Br** with a peak maximum at 575 nm. At room temperature, the emission decay curve contains two components with lifetimes of 11 ns and 657 ns. The time-resolved spectrum from 0 to 30 ns shows a blue-shift compared to the steady state spectrum, which can be attributed to a more localized excited state. The microsecond range emission, on the contrary, lines up well with steady-state fluorescence, indicating that both prompt and delayed emission are from the same singlet excited state. The time-resolved spectrum with a 1 ms delay shows a slight offset compared to the steady state spectrum, which results from the small  $\Delta E_{ST}$ . This long-lived RTP has a lifetime of 8 ms. Temperature-dependent studies give a  $\Delta E_{ST}$  of 50 meV from time-resolved spectra at 77 K and 62 meV from the Arrhenius plot, in agreement with the TDDFT singlet–triplet gap between the lowest singlet and the triplet state just below  $S_1$  computed at  $\sim 40$ –85 meV (Table S7, ESI†). Meanwhile, the low temperature phosphorescence displays a 69 ms lifetime.

Pyridinium and quinolinium cations with a bromide anion (**Py-Br** and **Qui-Br**) exhibit simultaneous TADF and RTP in the crystalline state under ambient conditions. Moreover, the heavy-atom effect from the Br atom in these two compounds (Tables S9 and S10, ESI†) enables extremely fast RISC and thus short lifetimes of the delayed fluorescence, which is beneficial for prolonging OLED device lifetime and suppressing efficiency roll-off in devices.<sup>31</sup>

Compounds **Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl** and **Qui-BF<sub>4</sub>** were also studied by similar photoluminescence lifetime measurements

as for **Py-Br** and **Qui-Br**. However, these compounds only exhibit mono-exponential fluorescence decays with no delayed component observed. Computed singlet–triplet gaps in **Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl** and **Qui-BF<sub>4</sub>** are very close to the one obtained for **Py-Br** regardless of the counter anion. Moreover, the nature of the electronic states does not change with different counter anions. Therefore, we hypothesize that the lack of delayed fluorescence with **BF<sub>4</sub><sup>-</sup>**, **Cl<sup>-</sup>** and **PF<sub>6</sub><sup>-</sup>** counter anions is due to weak RISC, which increases in **Py-Br** through the heavy atom effect. As shown in Fig. S6 (ESI†), the fluorescence lifetimes of these compounds in the crystalline state are all longer than 50 ns, that is, longer than conventional organic fluorophores. This can be attributed to the intermolecular and cation–anion interactions between the pyridinium group and the counter ions in the solid state. Steady-state photoluminescence reveals that anions can affect the emission wavelength of pyridinium compounds (**Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>** and **Py-Cl**). **Py-PF<sub>6</sub>** has an emission maximum at 442 nm while **Py-Cl** shows a red-shifted emission at 490 nm.

Time-resolved spectra of all four compounds (**Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl** and **Qui-BF<sub>4</sub>**) display separation from the steady-state emission (Fig. 5a), indicative of a second emissive excited state. **Py-BF<sub>4</sub>** has a peak maximum at 465 nm in the steady state spectrum. However, when a 1 ms delay is employed, a maximum at 512 nm is observed, with a shoulder at 540 nm. The delayed luminescence of the pyridinium compounds (**Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl**) shares the same trend as seen in the steady-state

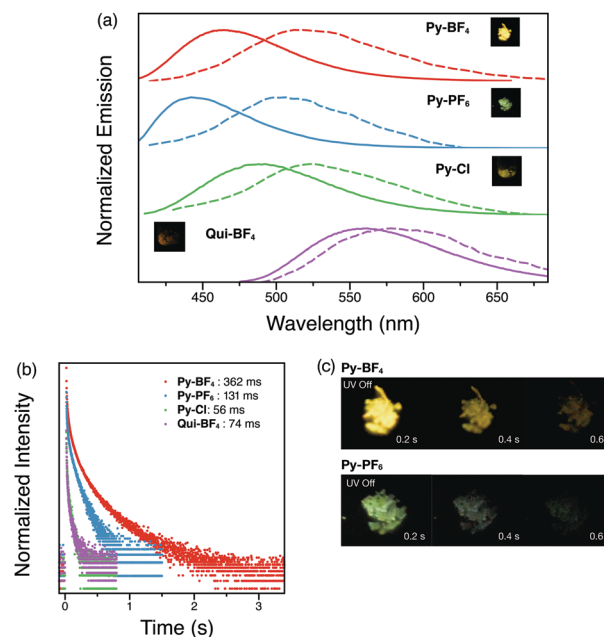

Fig. 5 (a) Steady-state (solid lines) and time-resolved with 1 ms delay (dashed lines) photoluminescence spectra of **Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl** and **Qui-BF<sub>4</sub>** crystalline powders under ambient conditions. Inset: Photographs of **Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl** and **Qui-BF<sub>4</sub>** crystalline powders when UV excitation is removed. (b) Phosphorescence decay profiles of **Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl** and **Qui-BF<sub>4</sub>** crystalline powders under ambient conditions. (c) Photographs of **Py-BF<sub>4</sub>** and **Py-PF<sub>6</sub>** over 0.6 s when UV excitation is removed.

emission, in which a red-shift from non-coordinating  $\text{PF}_6^-$  to coordinating  $\text{Cl}^-$  is observed.

All four compounds (**Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl** and **Qui-BF<sub>4</sub>**) display long-lived lifetimes (longer than milliseconds)<sup>34–37</sup> with visually observable afterglows that can be captured by a digital single-lens reflex (DSLR) camera, which is a characteristic feature of RTP (Fig. 5). **Py-BF<sub>4</sub>** has the longest lifetime (362 ms), while **Py-PF<sub>6</sub>** exhibits a shorter lifetime (131 ms). This can be rationalized by analyzing the crystal packing modes. The larger size of the  $\text{PF}_6^-$  counter anion prevents close interaction between triplet chromophores thus shortening the lifetime. **Py-Br** and **Py-Cl** have even shorter lifetimes, despite the fact that **Py-Br** and **Py-Cl** have shorter interaction distances than those of **Py-PF<sub>6</sub>**. This could be the result of water molecules in the crystal cavities. **Qui-BF<sub>4</sub>**, however, displays a 74 ms lifetime, which is a 5-fold decrease compared to its pyridinium counterpart (**Py-BF<sub>4</sub>**). Even though **Qui-BF<sub>4</sub>** has more short contacts and  $\pi-\pi^+$  and  $\pi^+-\pi^+$  interactions in the crystal structure, the triplet carbazole chromophores cannot effectively interact with each other, which might lead to the decrease in lifetime. More interestingly, **Py-BF<sub>4</sub>** shows persistent yellow ‘afterglow’ for 1 s after UV excitation is removed, whereas **Py-PF<sub>6</sub>** exhibits a green afterglow, both observable by the naked eye, which makes them potential candidates for anti-counterfeiting inks and for application in data encryption technology.

Low temperature studies in the crystalline state were also carried out (Fig. 6). The 1 ms delayed spectra exhibit similar phosphorescence at 500–650 nm as well as some new emission bands in the higher energy region possibly due to the more compacted packing. Measured lifetimes range from 779 ms to 1913 ms, demonstrating that at low temperature, molecular motions have been further suppressed. These findings provide a novel and facile toolkit to tune fluorescence and phosphorescence, in addition to RTP lifetimes through choice of anions.

Conversely, **Py-I** in the single crystalline state does not exhibit any photoluminescence at room temperature in air or under vacuum. Variable temperature photoluminescence studies were employed to understand the excited state of this compound. At temperatures above 150 K, the photoluminescence is extremely weak. However, when cooled to 100 K, **Py-I** exhibits green emission with a peak at 505 nm (Fig. 7). At 77 K,

Fig. 7 Variable temperature steady-state and time-resolved photoluminescence spectra of **Py-I**.

this broad emission peak grows drastically and gives relatively strong green luminescence. A time-resolved spectrum with 0.5 ms delay at 77 K is identical to the steady-state spectrum, indicating that emission originates from the long-lived triplet excited state. Therefore, by changing the anion to  $\text{I}^-$ , room temperature luminescence is completely quenched and the phosphorescence pathway is only activated at low temperature.<sup>38</sup> We tentatively hypothesize that the emission in **Py-I** is quenched by the low-energy CT excitations from the halogen to pyridinium (not present with the other anions).

To further expand the scope and examine the general applicability of this approach, a phenothiazine-5,5-dioxide moiety was used to replace the carbazole group as the triplet emitter (Scheme 2). Even though the RTP behavior of compounds containing this functional group has been thoroughly studied,<sup>39–41</sup> reports of TADF from compounds containing phenothiazine-5,5-dioxide are scarce.<sup>17</sup> Therefore, it is of interest to see whether incorporation of a bromide anion can enhance RISC in such systems as well. Unlike the **Py-CBZ** compounds, the structure of **Py-Cs-Br** is both water and  $\text{CH}_2\text{Cl}_2$  solvated, and the crystal packing modes of **Py-Cs-Br** and **Py-Cs-BF<sub>4</sub>** differ. In **Py-Cs-BF<sub>4</sub>**, the interaction between the phenothiazine-5,5-dioxide moiety and pyridinium group are stronger as they are close in space. However, the **Py-Cs-Br** single crystal sample still maintains a TADF feature with a 2.61  $\mu\text{s}$  delayed component (Fig. S7(b), ESI<sup>†</sup>). The RTP lifetime of **Py-Cs-Br** is 125 ms, longer than for **Py-Br**. **Py-Cs-BF<sub>4</sub>**, on the other hand, exhibits a slight amount of TADF in the single crystal phase as shown in Fig. S8(b) (ESI<sup>†</sup>). Similarly, it has a longer RTP lifetime, compared to **Py-Cs-Br**. Even though crystal packing might play a role in the differing photophysical behavior between **Py-Cs-Br** and **Py-Cs-BF<sub>4</sub>**, it can be concluded that in general, the anion can regulate TADF and RTP behavior in such  $\pi-\pi^+$  building blocks.

Fig. 6 (a) Steady-state (solid lines) and time-resolved with 1 ms delay (dashed lines) photoluminescence spectra of **Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl** and **Qui-BF<sub>4</sub>** crystalline powders at 77 K. (b) Phosphorescence decay profiles of **Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl** and **Qui-BF<sub>4</sub>** crystalline powders at 77 K.

Scheme 2 Chemical structures of pyridinium compounds with phenothiazine-5,5-dioxide group.

**Fig. 8** (a) Steady-state (blue) and time-resolved with 1 ms delay (orange) photoluminescence spectra of **Py-A** single crystal under ambient conditions. Inset: Photograph of **Py-A** single crystals when UV excitation is removed. (b) Fluorescence decay profile of **Py-A** single crystal under ambient conditions. (c) Phosphorescence decay profile of **Py-A** single crystal under ambient conditions.

To further demonstrate the influence anions can have on triplet luminescence processes, equimolar quantities of **Py-BF<sub>4</sub>** and **Py-Br** were mixed and co-crystallized from an acetone solution to form an organic co-crystal (**Py-A**).<sup>42,43</sup> The obtained single crystal contains **BF<sub>4</sub><sup>-</sup>** and **Br<sup>-</sup>** anions in a 2:3 molar ratio. Interestingly, TADF and RTP properties originating from the parent compounds **Py-BF<sub>4</sub>** and **Py-Br** are maintained in the alloy. The steady-state spectrum of **Py-A** displays a peak at 475 nm, intermediate in energy between the maxima of parent compounds **Py-BF<sub>4</sub>** and **Py-Br** (Fig. 8a). **Py-A** exhibits a characteristic red-shifted phosphorescence spectrum when a 1 ms delay was employed with yellow afterglow observed. As a result, the singlet-triplet energy gap is larger than that of **Py-Br** but smaller than that of **Py-BF<sub>4</sub>** demonstrating how TADF and RTP can be controlled. The amplitude of the delayed component of the TADF feature decreases and the RTP lifetime is prolonged compared to **Py-Br** (Fig. 8b and c). These results clearly show that manipulation of anions can effectively regulate the TADF and RTP features in an organic salt system.

## Conclusions

Seven carbazole-containing pyridinium and quinolinium compounds, two phenothiazine-containing pyridium compounds and one organic co-crystal are reported where the specific anion present plays a role in tuning the photophysical properties. These compounds adopt similar molecular structures and packing modes with different anions present and exhibit three

types of photophysical behaviors due to the electronic effects from the anions. **Py-Br**, **Qui-Br** and **Py-Cs-Br** exhibit TADF with some RTP observed, these are the first examples to achieve these two interesting photophysical phenomena using a bromide anion. These compounds show fast reverse intersystem crossing and a short delayed lifetime, which is key to application in efficient and robust OLEDs. **Py-BF<sub>4</sub>**, **Py-PF<sub>6</sub>**, **Py-Cl**, **Qui-BF<sub>4</sub>** and **Py-Cs-BF<sub>4</sub>** display RTP with long-lived lifetimes and afterglow can be clearly observed by eye once the UV excitation is removed. This behavior can be further utilized for data encryption and anti-counterfeiting applications. Emission wavelengths and lifetimes are also dependent on the specific anions.

Two examples of N-heterocyclic cations and triplet emitters demonstrate the general applicability of using anions to regulate photoluminescence. By altering the anions, reverse intersystem crossing rate can be tuned to tailor the desired photophysical behaviour. The showcasing of a co-crystal also expands the scope of this strategy and fine-tuning of TADF and RTP can be realized through co-crystallization. Previously reported cases utilized only the heavy-atom effect from halogen anions to achieve RTP. A key feature here is that the cation is involved in the low excited state transitions through interaction with the triplet emitters. These counter-intuitive results also open up an avenue for developing luminescent materials through anion tuning. Moreover, this approach enhances the design principles behind TADF and RTP materials and presents a molecular model to understand the interplay of RTP and TADF.

## Conflicts of interest

There are no conflicts to declare.

## Acknowledgements

M. O. W. acknowledges the Natural Sciences and Engineering Research Council of Canada for funding. D. C. acknowledges financial support from the Spanish Government MINECO/FEDER (project PID2019-109555GB-I00) and the Eusko Jaurlaritza (Basque Government, projects IT1254-19 and PIBA19-0004). C. C. is indebted to the European Research Council (ERC-2016-STG-714870) for a postdoctoral contract. We acknowledge the Laboratory for Advanced Spectroscopy and Imaging Research (LASIR) for facilities access and would like to thank Dr Saeid Kamal for assistance with spectroscopic studies and Anita Lam for pXRD measurements.
