Heavy metals removal by EDTA-functionalized chitosan graphene oxide nanocomposites†

Asif Shahzad,^a Waheed Miran,^a Kashif Rasool,^b Mohsin Nawaz,^a Jiseon Jang,^a Seong-Rin Lim^{*c} and Dae Sung Lee^{*a}

Graphene-based two-dimensional materials have been explored in a variety of applications, including the treatment of heavy-metal-rich water/wastewater. Ethylenediaminetetraacetic acid (EDTA)-functionalized magnetic chitosan (CS) graphene oxide (GO) nanocomposites (EDTA-MCS/GO) were synthesized using a reduction precipitation method and applied to the removal of heavy metals, such as Pb²⁺, Cu²⁺, and As³⁺, from aqueous solutions. The synthesized nanocomposite was characterized by FT-IR, XRD, SEM, MPMS, zeta-potential and BET analyses. The influence of various operating parameters, such as pH, temperature, metal ion concentration, and contact time on the removal of the metal ions, was investigated. Owing to the large specific surface area, hydrophilic behavior, and functional moieties, the magnetic nanocomposite demonstrated excellent removal ability with a maximum adsorption capacity of 206.52, 207.26, and 42.75 mg g⁻¹ for Pb²⁺, Cu²⁺, and As³⁺, respectively. The equilibrium data was evaluated by Langmuir and Freundlich isotherms, while the heavy metal adsorption reaction kinetics was analyzed by Lagergren pseudo-first-order and pseudo-second-order kinetic models. The nanocomposite was reused in four successive adsorption–desorption cycles, revealing a good regeneration capacity of the adsorbent.

1. Introduction

The discharge of wastewater containing heavy metals into the environment has increased continuously as a result of various industrial activities, such as metal finishing, electroplating, metal smelting, chemical engineering, papermaking, mining, and agriculture.^{1,2} Heavy metal contamination in such effluents presents a serious threat to the environment and human health because of their toxicity, non-biodegradability, carcinogenicity, and bioaccumulation in living organisms.^{3,4} For instance, Pb poses several risks to human health, causing insomnia, pain, dizziness, anemia, irritability, muscle weakness, hallucinations, and renal damage.⁵ Cu can also have serious toxicological effects *via* short or long-term exposure to the human body, such as gastrointestinal illness, vomiting, cramps, convulsions, or even death.⁶ The presence of As in water/wastewater above the suggested safe amounts is toxic and carcinogenic and poses other health hazards. Long-term exposure to As in drinking water may cause cancer, changes to skin color, neural disorders,

muscular weakness, loss of appetite, and nausea.^{7,8} Therefore, heavy metals are important environmental concerns with adverse links to human health and the economy.⁹ These issues require effective treatment of heavy-metal-rich wastewater to decrease pollutants to acceptable levels.

In this regard, many techniques have been developed for the removal of heavy metals from wastewater, such as chemical precipitation, ion exchange, reverse osmosis, membrane filtration, electrolysis, and adsorption. Among these, adsorption is the preferred technology because of its simplicity, effectiveness, and low cost in the removal of toxic heavy metals from water/wastewater.¹⁰ Moreover, the simple operation, time efficiency, and large-scale applicability of the adsorption method are considered promising for the development of wastewater treatment technologies. In recent years, carbonaceous nanomaterials such as graphene oxide (GO), a two- or three-dimensional nanosheet, have attracted the attention of researchers because of their unique properties and large composition diversity. The presence of a wide range of consecutive oxygen functional groups on the GO surface and large surface area are characteristics that make GO an excellent adsorbent for the removal of heavy metals and several other pollutants.¹¹ Moreover, the large specific surface area of GO provides abundant attachment sites for the functionalization of other compounds, such as chitosan (CS) and ethylenediaminetetraacetic acid (EDTA). This can ultimately increase the number of surface functional groups, which might enhance heavy metal adsorption. CS with primary amino groups is easily

functionalized with different organic ligands, such as GO and EDTA, to improve its adsorption capacity. EDTA has many applications, including as a dyeing auxiliary, stabilizer, softener, and in coordination titration.¹² In previous studies, EDTA chelation with divalent metals has been reported, in which one carboxyl group is freely available and one water molecule is coordinated to the metal center.^{12,13} Therefore, EDTA is a good candidate for the adsorption of heavy metals and can be functionalized with other materials such as GO and CS. Many nanomaterials, functionalized with EDTA and CS, have been reported and they showed significant adsorption behaviors towards divalent heavy metals such as Co, Hg, and Cu in aqueous solution.^{12,13} However, it is necessary to develop a novel material which can remove both divalent heavy metals and trivalent ones such as As³⁺ from drinking water as well as from industrial wastewater.

In this study, EDTA-functionalized magnetic chitosan graphene oxide (EDTA-MCS/GO) nanocomposites are synthesized using a reduction precipitation method.¹⁴ This preparation method is inexpensive, rapid and does not require reactive gases or toxic cross-linking agents. The method can proceed at room temperature, thus representing a significant improvement over previously available synthetic methods.¹⁵ Magnetic properties were also incorporated into the nanocomposites to allow the used adsorbent to be easily retrieved from an aqueous solution after the adsorption of heavy metals. The adsorption behavior of synthesized EDTA-MCS/GO nanocomposites was investigated for divalent Pb²⁺, Cu²⁺, and trivalent As³⁺ ions in aqueous solution.

2. Experimental work

2.1. Synthesis of EDTA-MCS/GO

GO was synthesized using a modified Hummers' method.¹⁶ The synthesis of EDTA-MCS/GO was a two-step process. In the first step, FeCl₃·6H₂O (1.22 g) was dispersed in HCl (35.0 mL, 0.1 M). CS (2.0%) solution was obtained by dissolving low weight CS in 1.0% HCl. GO (15.0 mL, 0.33 wt%) solution, CS (2.5 mL, 2.0 wt%) solution, and distilled water (7.5 mL) were added together and vigorously stirred for 1 h at room temperature. Later, produced FeCl₃ solution and Na₂SO₃ (15 mL, 0.19 g) solution were added to the mixture with continuous stirring for 30 min, resulting in a solution color change from brownish to blackish. Then, NH₃ (16.0 mL, 14%) was added to induce the precipitation of a blackish material. The obtained product (MCS/GO) was washed several times with DI water and absolute ethanol, and finally dried in an oven at 60 °C. In the second step, Na₂EDTA (45 mL, 13.3 wt%) and dried ground MCS/GO (20 mL, 5.0 wt%) dispersions were mixed and allowed to react for 24 h at room temperature. The resultant product (EDTA-MCS/GO) was separated using a magnet and purified by washing several times with DI water and absolute ethanol. Finally, the synthesized EDTA-MCS/GO nanocomposite was oven dried at 60 °C then manually grinded into a fine powder for adsorption studies.

2.2. Characterization of EDTA-MCS/GO

Fourier transform infrared (FT-IR) spectroscopy, X-ray diffraction (XRD), scanning electron microscopy (SEM), magnetic

property measurement system (MPMS), zeta-potential and Brunauer–Emmett–Teller (BET) measurements were used to characterize the synthesized EDTA-MCS/GO nanocomposite. The FT-IR spectrum was recorded in the spectral range 4000–400 cm⁻¹ on an FT-IR spectrometer (Perkin-Elmer, USA). XRD was performed using an X-ray diffractometer (D/Max-2500, Rigaku) with Cu K α radiation ($\lambda = 1.5406 \text{ \AA}$) in the scanning range 0–80° (2 h). SEM (HITACHI S-4800, Japan) was used to obtain micro-level features of EDA-MCS/GO. For MPMS analysis, MPMS SQUID VSM (Quantum Design Inc. USA) was used and zeta-potential values were measured using Zetasizer Nano ZS (Malvern Instruments). Nitrogen gas adsorption–desorption onto EDTA-MCS/GO was performed to evaluate the nanocomposite BET surface area (Quantachrome version-5.04, America).

2.3. Adsorption experiments

In order to study the adsorption behaviors of heavy metals onto the synthesized EDTA-MCS/GO nanocomposites, batch adsorption experiments were conducted. The Pb²⁺, Cu²⁺, and As³⁺ sources were PbCl₂, Cu₂(NO₃)₂·3H₂O, and As₂O₃, respectively. PbCl₂ and Cu₂(NO₃)₂·3H₂O solutions were prepared in DI water, whereas the As₂O₃ solution was obtained in 0.2 M NaOH. The pH values of the metal ion solutions were adjusted by 0.1 M HNO₃ or 0.1 M NaOH solutions. Adsorption studies were performed by adding 0.33 g L⁻¹ EDTA-MCS/GO to 30 mL of each metal ion solution. The initial concentrations of Pb²⁺, Cu²⁺, and As³⁺ were 50, 50, and 5 mg L⁻¹, respectively. Initial adsorption experiments were performed at 180 rpm and 25 °C in a shaking incubator. Aliquots were drawn at pre-determined time intervals and the adsorbent was separated using an external magnet. The supernatant was used to analyze the residual metal ion concentrations by inductively coupled plasma optical emission spectroscopy (ICP-OES; Perkin-Elmer Optima 2100 DV). The effects of different operational parameters, such as contact time, solution pH, metal ion concentration, and reaction temperature, were studied to optimize the adsorption efficiency. The adsorption kinetics was investigated at 298 K with the initial concentrations of the individual metal ions solution as stated above. In order to study adsorption isotherms, experiments were conducted under optimal conditions. The adsorption capacity (q_e) of the metal ions and removal efficiency (%) onto EDTA-MCS/GO nanocomposites at the equilibrium stage were calculated using the following equations:

$$q_e = \frac{(C_o - C_e) V}{m} \quad (1)$$

$$\text{Removal efficiency (\%)} = \frac{(C_o - C_e)}{C_o} \times 100 \quad (2)$$

where q_e is the adsorption capacity (mg g⁻¹), C_o is the initial heavy metal ion concentration in solution (mg L⁻¹), C_e is the equilibrium concentration (mg L⁻¹) after adsorption, V is the solution volume (L), and m is the mass of EDTA-MCS/GO adsorbent (g). Metal ions loaded EDTA-MCS/GO were dissolved separately in 0.1 M HCl solution and agitated for 5 h in a shaking incubator at room temperature. After washing several

times with DI water till pH 6–7, the nanocomposite was dried in an oven and used in successive adsorption–desorption cycles. All the experiments were performed in triplicate and average values were reported.

3. Results and discussion

3.1. Characterization of EDTA-MCS/GO

The FT-IR results confirmed that EDTA-MCS/GO contained numerous oxygen and nitrogen functional groups (Fig. 1a). A broad band observed at 3430.44 cm^{-1} was assigned to O–H or N–H stretching vibrations from adsorbed H_2O or $-\text{NH}_2$ groups of CS on the surface of EDTA-MCS/GO.¹⁷ The band at 583.54 cm^{-1} was recognized as Fe–O bond stretching of Fe_3O_4 in EDTA-MCS/GO.¹⁸ The stretching vibration and bending vibration of the N–H bond appeared in a band at 1076.08 cm^{-1} , which was assigned to $-\text{NH}_2$ groups in EDTA or CS on the surface of EDTA-MCS/GO. Another vibrational band at 1380.64 cm^{-1} was assigned to C–OH.¹⁹ A strong band at 1630 cm^{-1} was attributed to C=O bond vibrations in carboxyl functional groups. Bands at 2920 and 2845 cm^{-1} resulted from C–H bonds in alkane groups. These O and N functional groups could act as available adsorption sites and play important roles in the removal of metal ions from aqueous solutions.^{12,20,21}

The crystalline structure of synthesized EDTA-MCS/GO nanocomposites was explained well by the corresponding XRD pattern (Fig. 1b). The GO peak was found at around $2\theta = 10^\circ$ in the GO XRD curve. According to the JADE PDF card (89-4319), several sharp and strong diffraction peaks in EDTA-MCS/GO curve, ranging from $2\theta = 30.18$ – 80° in the XRD crystal lattice planes, were attributed to magnetite. The XRD pattern exhibited a peak at $2\theta = 20.70^\circ$, which indicated the amorphous behavior of CS.²² A peak around 18.32° might be evidence of the presence of EDTA.¹² These several expressive diffraction peaks in the XRD analysis confirmed that the desired product, EDTA-MCS/GO nanocomposite, had been successfully synthesized.

BET analysis was employed to configure the surface area of the nanocomposites. The surface area of the adsorbent plays a key role in adsorption phenomena. The best adsorption capacities should be achieved by large specific surface area of the adsorbent material. The multi-point BET surface area of EDTA-MCS/GO was $81.36\text{ m}^2\text{ g}^{-1}$, which was approximately twice that of previously reported for EDTA-MGO

nanocomposites.¹² This increase in surface area might be due to CS and the newly proposed synthetic method, which made the nanocomposites more suitable for divalent and trivalent ion adsorption. According to IUPAC 1984, the N_2 adsorption–desorption isotherm of EDTA-MCS/GO obeyed a type IV hysteric loop (Fig. 2a), which demonstrated good adsorbent–adsorbate interactions. This high surface area benefitted the adsorption of metal ions.

SEM was performed to investigate the surface morphologies and structures of the EDTA-MCS/GO nanocomposites. The magnified SEM image (Fig. 2b) of GO revealed a sheet-like structure of sp^2 -hybridized carbon atoms with a smooth surface and crumpled edges. The SEM image in Fig. 2c shows small rounded magnetic chitosan (MCS) particles distributed roughly onto the GO surface. CS was well dispersed with GO and showed a close attachment, which indicated bonding between GO and CS. By adding EDTA, the size of magnetic particles increased. Therefore, comparatively large, rounded magnetic EDTA-CS particles were observed on the surface of the GO sheets (Fig. 2d). Various nano-scale EDTA-MCS particle clusters were widely spread over the surface of the GO sheets. This phenomenon increased the surface availability of the nanocomposites for adsorption and prevented GO agglomeration.² Numerous hydrophilic functional groups, such as $-\text{OH}$ and $-\text{COOH}$, on the GO sheet-like structures were readily available to different chelating moieties.²³ Therefore, EDTA functional groups and amino groups present in CS could form chemical bonds with the GO sheet surface.

A typical magnetic hysteresis loop of EDTA-MCS/GO was identified in MPMS profile (Fig. S1†). At room temperature, the saturation magnetization was 60.84 emu g^{-1} . With almost zero coercivity and zero remanence in the magnetization curve, the synthesized EDTA-MCS/GO nanocomposite showed supermagnetic properties.²⁴ The pH zero point charge (pH_{zpc}) determines the electrophoretic mobility where the net total particle charge is zero.²⁵ In zeta potential analysis of EDTA-MCS/GO, the pH_{zpc} value was 3.8 and the composite was negatively charged after pH 3.8 (Fig. S2†).

3.2. Metal ion adsorption

3.2.1. Effect of solution pH, contact time, temperature, and initial metal concentration. In water/wastewater treatment, pH

Fig. 1 (a) FT-IR spectra and (b) XRD patterns of GO and EDTA-MCS/GO nanocomposites.

is a key operational parameter, as it can influence both the adsorbent structure and the distribution of pollutant species. Therefore, the effect of pH was studied in the removal of metal ions from aqueous solution using the synthesized adsorbent. The uptake efficiency in the pH range was examined with initial concentrations of 50 mg L^{-1} for Pb^{2+} and Cu^{2+} , and 5 mg L^{-1} for As^{3+} . Metal ion adsorption onto the EDTA-MCS/GO nanocomposite was strongly dependent upon the initial pH. An increase in Pb^{2+} removal was noted with increasing pH up to 5.0, while a sudden decrease in adsorption was observed at higher pH values, as shown in Fig. S3.† Cu^{2+} removal increased gradually with increasing pH, with maximum adsorption occurring at pH 5.5 (Fig. S3†), but pH 8.0 was found to be optimal pH for As^{3+} adsorption (Fig. 4a). Adsorption densities of 134.82, 119.91, and 11.50 mg g^{-1} were obtained for Pb^{2+} , Cu^{2+} , and As^{3+} , respectively, at the corresponding optimum pH. In the removal of all cationic metal ions, the adsorption capacities were highest at higher pH values, and *vice versa*. A pH value >5.0 was reported to be favorable for the removal of different cationic metal ion by GO-based adsorbents.²⁶ The EDTA-MCS/GO surface contained hydrophilic functional groups ($-\text{OH}$, $-\text{COOH}$, and $-\text{NH}_2$), so at lower pH values, the nanocomposites became positively charged due to protonation, with electrostatic repulsion causing weak bonding between cationic metals ions and the adsorbent. By increasing the pH, the charges on the adsorbent surface (H_3O^+) became weaker, and competition between H_3O^+ and the metal ions might occur. This phenomenon could cause an increase in the electrostatic attraction of the positively charged metal ions to the nanocomposite surface.^{27,28} Moreover, in zeta potential analysis pH_{zpc} was about 3.8 and positive zeta potential values were measured below pH_{zpc} , proving H^+ competition upon adsorbent-adsorbate

interaction. Therefore, at higher pH ($\text{pH} > 3.8$) the nanocomposite surface was negatively charged, which increased the adsorption of positively charged metal ions. Therefore, optimum pH values of 5, 5.5, and 8.0 were chosen for further experiments involving Pb^{2+} , Cu^{2+} , and As^{3+} , respectively.

The adsorption of metal ions on the EDTA-MCS/GO nanocomposite increased with increasing contact time, and an equilibrium was reached within 5 h for Pb^{2+} and Cu^{2+} , and 11 h for As^{3+} . The metal removal rate at the initial contact time was high, which could be attributed to the large number of vacant binding sites available for metal ion adsorption to the nanocomposite surfaces. As the exterior surface became exhausted, the adsorbate uptake rate began to decrease, eventually reaching an apparent equilibrium. A fast adsorption process was observed for Pb^{2+} and Cu^{2+} metal ions, which might be due to the strong chemical bonding between metals ions and oxygenated groups in the EDTA-MCS/GO nanocomposites. In contrast, the As^{3+} adsorption equilibrium was established more slowly, which could be sign of poor bonding interactions (compared with Pb^{2+} and Cu^{2+}) between the adsorbent and adsorbate. Furthermore, EDTA is a hard ligand, so its functional groups easily form strong bonds with hard metals, such as Pb^{2+} and Cu^{2+} , but comparatively weak bonds with soft transition metals, such as As^{3+} .²⁹ Nevertheless, As^{3+} adsorption efficiency was still very good, which might be due to the presence of CS in EDTA-MCS/GO. The heterogeneous adsorbent surface might cause the variation in bonding interactions among the different metal ions.

The initial metal ion concentrations had a significant effect on their removal from aqueous solutions. The adsorption densities of Pb^{2+} and Cu^{2+} on the nanocomposite increased from 26.62 and 27.12 to 209.49 and 195.57 mg g^{-1} , respectively,

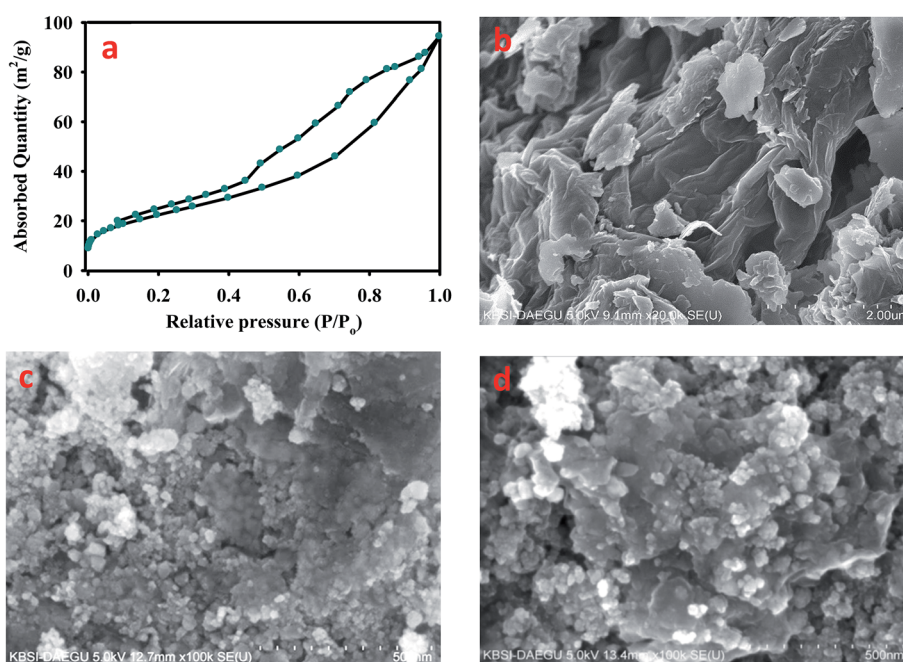

Fig. 2 (a) BET analysis of EDTA-MCS/GO nanocomposites with nitrogen adsorption and SEM images of (b) GO, (c) MCS/GO, and (d) EDTA-MCS/GO nanocomposites.

Fig. 3 Pseudo-second-order curve-fitting graphs of (a) Pb^{2+} , (b) Cu^{2+} , and (c) As^{3+} at 298.15 K. (d) Adsorption profiles of Pb^{2+} , Cu^{2+} , and As^{3+} on EDTA-MCS/GO nanocomposite at different metal ion concentrations.

with increase in the initial metal ion concentration was increased from 10 to 150 mg L^{-1} . Similarly, the nanocomposite As^{3+} adsorption capacity increased from 11.50 to 38.24 mg g^{-1} when the initial As^{3+} concentration was increased from 5 to 100 mg L^{-1} (Fig. 3). Higher initial metal ion concentrations resulted in higher mass gradient pressures between the aqueous solution and nanocomposite, which may provide a driving force to overcome the mass transfer resistance between the aqueous and solid phases.

To determine the effect of temperature on the metal ion adsorption by the EDTA-MCS/GO nanocomposites, experiments were carried out at 298, 303, and 313 K while keeping all the other parameters, such as the concentrations of adsorbate and adsorbent, pH, and agitation speed, constant. The Pb^{2+} and Cu^{2+} adsorption densities decreased significantly from 134.82 and 95.91 mg g^{-1} to 119.91 and 60.6 mg g^{-1} , respectively, as the temperature increased from 298 to 313 K, using an initial metal concentration of 50 ppm. In contrast, a slight increase in adsorption, from 11.50 to 11.96 mg g^{-1} was observed for As^{3+} with the temperature increase from 298 to 313 K. These results showed that Pb^{2+} and Cu^{2+} adsorption on the EDTA-MCS/GO

nanocomposite were exothermic processes, while As^{3+} adsorption might be slightly endothermic. Therefore, metal ion adsorption by the EDTA-MCS/GO nanocomposite was significantly affected by temperature.

3.2.2. Adsorption kinetics. The adsorption kinetics for Pb^{2+} , Cu^{2+} , and As^{3+} removal were analyzed using Lagergren's pseudo-first-order (3) and pseudo-second-order kinetics models (4):

$$\ln(q_e - q_t) = \ln q_e - k_1 t \quad (3)$$

$$\frac{t}{q_t} = \frac{1}{k_2 q_e^2} + \frac{t}{q_e} \quad (4)$$

where q_t is the metal ion concentration (mg g^{-1}) at any given time (t), q_e is the metal ion equilibrium concentration, k_1 is the first-order rate constant (h^{-1}), and k_2 is the second-order rate constant ($\text{g mg}^{-1} \text{h}^{-1}$). Table 1 depicts the kinetics parameters obtained from these two kinetic models. Lagergren's pseudo-first-order model did not fit the entire range of the adsorption process well and was only applicable over the initial contact times (Fig. S4†). The values of the regression coefficients were

Table 1 Pseudo-first- and second-order rate constants for Pb^{2+} , Cu^{2+} , and As^{3+} adsorption onto EDTA-MCS/GO at pH 5, 5.5, and 8, respectively

| Target pollutant | 1 st order | | | 2 nd order | | | Experimental q_e |
|------------------|-----------------------|-------|-------|-----------------------|-----------|-------|-----------------------|
| | q_e | K_1 | r^2 | q_e | K_2 | r^2 | |

| Cu^{2+} | 92.57 | 1.241 | 0.731 | 120.48 | 0.0000083 | 0.994 | 119.91 |
| As^{3+} | 8.19 | 0.207 | 0.771 | 12.18 | 0.60996 | 0.980 | 11.50 |

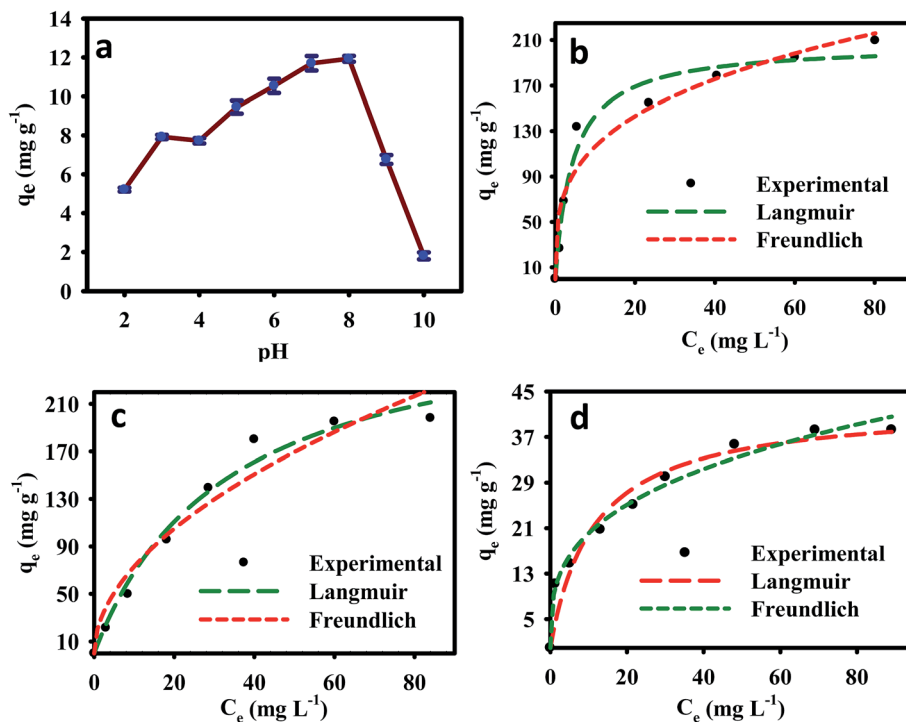

Fig. 4 (a) Effect of pH on As³⁺ removal and (b–d) adsorption isotherm model fits for Pb²⁺, Cu²⁺, and As³⁺ adsorption onto EDTA-MCS/GO.

quite low ($r^2 = 0.891, 0.731, \text{ and } 0.771$ for Pb²⁺, Cu²⁺, and As³⁺, respectively) and the experimental q_e values were in good agreement with the theoretical values calculated by the pseudo-second-order equation. The pseudo-second-order kinetic model provided better correlation with the adsorption of metal ions on the EDTA-MCS/GO nanocomposites, with higher r^2 values (0.996, 0.994, and 0.980 for Pb²⁺, Cu²⁺, and As³⁺, respectively) compared with the pseudo-first-order model. Moreover, the calculated adsorption capacities from the pseudo-second-order equations were near the experimental values. The pseudo-second-order model gave the best fit for the chemical interactions between the nanocomposite functional groups and the adsorbed Pb²⁺, Cu²⁺, and As³⁺ metal ions, and the adsorption process was concluded to involve chemisorption and to be the rate-limiting step (Fig. 3).

3.2.3. Adsorption isotherms. The metal ion adsorption isotherms of EDTA-MCS/GO were studied at different metal ion concentrations, while keeping all the other parameters constant. The maximum adsorption densities of Pb²⁺, Cu²⁺, and As³⁺ on the synthesized EDTA-MCS/GO nanocomposites

were 209.49, 195.57, and 38.23 mg g⁻¹, respectively (Fig. 3d). These adsorption capacities (q_e) for both divalent and trivalent metal ions were achieved using very small amounts of adsorbent (0.33 g L⁻¹). The synthesized adsorbent presented excellent sorption behavior towards heavy metal ions. Sorption isotherm models were used to analyze the nature of adsorbent–adsorbate interactions at equilibrium stages and determine the maximum heavy metal ion adsorption capacities of the synthesized nanocomposites. In this study, we used two equilibrium models to examine the experimental data: the Langmuir model (5),

$$q_e = \frac{q_{\max} K_L C_e}{1 + K_L C_e} \quad (5)$$

where q_{\max} (mg g⁻¹) is the maximum adsorption capacity of the adsorbent, and K_L (L mg⁻¹) is the Langmuir sorption constant related to the free energy of adsorption; and the Freundlich model (6),

$$q_e = K_f C_e^{1/n} \quad (6)$$

Table 2 Adsorption parameters of Langmuir and Freundlich adsorption isotherm models for Pb²⁺, Cu²⁺, and As³⁺ adsorption onto EDTA-MCS/GO

| Target pollutant | Langmuir | | | Freundlich | | |
|------------------|----------------------------------|-------|-------|-----------------------------|-------|-------|

where K_f (L g⁻¹) and n (dimensionless) are isotherm constants.

The experimental results, together with the non-linear Langmuir and Freundlich fits for Pb²⁺, Cu²⁺, and As³⁺, are plotted in Fig. 4b–d, respectively, and the isotherms parameters are summarized in Table 2. The Pb²⁺ and Cu²⁺ experimental data showed best fits for Langmuir isotherms because its regression coefficients ($r^2 = 0.967$ and 0.971) were higher than those of the Freundlich isotherm model ($r^2 = 0.931$ and 0.941). The adsorption of Pb²⁺ and Cu²⁺ was typically monomolecular layer adsorption. Furthermore, the maximum calculated amounts of adsorbed metal ions (q_{max}) from the Langmuir isotherm were 206.52, 207.26, and 42.75 mg g⁻¹ for Pb²⁺, Cu²⁺, and As³⁺ respectively. The regression coefficient of the Freundlich isotherm model for As³⁺ ($r^2 = 0.985$) was higher than that of the Langmuir isotherm model, which suggested that As³⁺ adsorption onto the EDTA-MCS/GO nanocomposites formed a monolayer on the heterogeneous adsorbent surface.

3.2.4. Reusability of EDTA-MCS/GO. The desorption capability of the synthesized nanocomposites was evaluated. Once an adsorption equilibrium achieved, the used nanocomposites were desorbed in acidic solution. The nanocomposites were reused in four adsorption–desorption cycles as can be seen in Fig. S5.† A small decreasing trend in all metal ions adsorption capacity was noticed in the adsorption–desorption cycles (Fig. S5†). Meanwhile, after four adsorption–desorption cycles, the EDTA-MCS/GO nanocomposite showed high magnetic sensitivity under an external magnetic field. The results showed that the synthesized nanocomposite can be used as a potentially good adsorbent to remove Pb²⁺, Cu²⁺, and As³⁺ simultaneously in aqueous solution.

3.2.5. Real wastewater assessment. The adsorbent performance of EDTA-MCS/GO in a real wastewater was investigated. The wastewater sample was taken from a domestic wastewater treatment plant. In Table S1† the chemical composition of wastewater is summarized. Then a known concentration of Pb²⁺, Cu²⁺, and As³⁺ ions were dissolved in the wastewater sample with the fixed amount of adsorbent (0.03 g L⁻¹). The adsorption process was continued for 24 h under an optimized condition. The maximum adsorption capacities of Pb²⁺, Cu²⁺, and As³⁺ were 116.16, 102.6, and 8.82 mg g⁻¹, respectively, which were 87.20, 86.77, and 80.39% of those in deionized water. The decrease of sorption capacities of heavy metal ions in domestic wastewater compared with those in deionized water may be caused by the increase of ionic strength in wastewater.

The presence of anions such as sulfate, phosphate, chloride, and nitrate was also observed in wastewater (as shown in Table S1†). These interfering anions might cause a decrease in metal ions adsorption capacity of EDTA-MCS/GO.

3.2.6. Adsorption evaluation. There are several adsorbents that could contribute to heavy metal removal from wastewater. EDTA-MCS/GO nanocomposite could be an important new adsorbent among recent advanced adsorbents developed for water/wastewater treatment systems. Using the minimum amount (0.33 g L⁻¹) of sorbent, we achieved q_{max} values of 206.52, 207.26, and 42.75 mg g⁻¹ for Pb²⁺, Cu²⁺, and As³⁺, respectively, which might be due to the conglomeration of EDTA, GO, and CS properties in a single composite. The adsorption capacities for metal ions removal in this study were much higher than those of many conventional and recently reported graphene-based adsorbents.²⁶ A comparison of different types of adsorbent with the synthesized EDTA-MCS/GO nanocomposite for their removal capabilities, adsorption isotherms, and adsorption kinetics is shown in Table 3.

4. Conclusion

This work demonstrated the efficient removal of divalent (Pb²⁺ and Cu²⁺) and trivalent (As³⁺) metal ions using EDTA-MCS/GO nanocomposite. The synthesized nanomaterial was characterized by SEM, FT-IR, MPMS, XRD, and zeta potential analyses. The pseudo-second-order kinetic model gave better correlation with the adsorptions of all the three metal ions than the pseudo-first-order one. Langmuir isotherms were the best fits for Pb²⁺ and Cu²⁺ adsorption, while the As³⁺ adsorption process was well described by its Freundlich isotherm. A chemical adsorption process of individual metal ions was suggested by kinetics and isotherm results. The synthesized nanocomposite exhibited a good regeneration capacity towards target metal ions after four successive adsorption–desorption cycles. Efficient removal of metal ions in real wastewater was also achieved. Therefore, EDTA-MCS/GO nanocomposite is a promising adsorbent for Pb²⁺, Cu²⁺, and As³⁺ removal from contaminated water/wastewater.
