Nitroenediamines (EDAMs), and N-methyl-1-(methylthio)-2-nitroethenamine (NMSM) derivatives: scaffolds for heterocycle molecular diversity (update from 2012 to 2021)

Fahimeh Abedinifar, D Bagher Larijani and Mohammad Mahdavi D*

Nitro-1,1-enediamines (EDAMs) and 1,1-bis(methylthio)-2-nitroethene (NMSN) have proven to be a class of attractive and useful synthetic building blocks for use in the synthesis of heterocyclic and fused heterocyclic compounds. The bicyclic or tricyclic heterocycles derived from these frames widely exist in natural and synthetic drugs. To comprehend the reaction properties of EDAMs and NMSN and to design other novel fused heterocycles with biological effects in the future, it is essential to investigate their recent reactions. The current review envisions highlighting some recent and remarkable examples of nitroenediamine reactions categorized by catalyst-assisted and catalyst-free reactions from 2012 onward.

1. Introduction

Nitro-1,1-enediamines (EDAMs) with the formula and structural features illustrated in Scheme 1, are fascinating and versatile building blocks that have been widely applied to synthesize a variety of functionalized fused heterocyclic compounds with diverse pharmacological activities including antitumor, ¹⁻³ antibacterial, ⁴ and antileishmanial. ⁵ EDAMs as bisnucleophilic reagents could react with various electrophiles to prepare highly functionalized heterocycles.

The reactant *N*-methyl-1-(methylthio)-2-nitroethenamine (NMSM) contains four active sites with three functional groups on an ethene motif, as shown in Scheme 1. A strongly electron-withdrawing nitro group makes the nitroethylene substructure a good Michael acceptor. Besides, the methylthio group acts as a leaving group and electron donor to make the C2 a good Michael donor. Also, the secondary amine group is an electron-donor. Overall, the ethylene moiety is a polarized push-pull alkene with C1 showing electrophilic character and C2 showing nucleophilic character. NMSM, with all these characteristics, is an important reactant that may cause the products more valuable as medical intermediates and in synthesizing a variety of oxygen and nitrogen-containing heterocyclic compounds.

Cyclic enediamine with a carbonyl group on α -carbon atom is known as heterocyclic ketene aminals (HAKs).⁶ These compounds are generally categorized as good nucleophiles in organic reactions. Furthermore, replacement of nitro group on

Endocrinology and Metabolism Research Center, Endocrinology and Metabolism Clinical Sciences Institute, Tehran University of Medical Sciences, Tehran 14176, Iran. E-mail: Momahdavi@sina.tums.ac.ir

 α -carbon generates a new class of HKAs and will be discussed in this review.

All of ketene aminals, keten thioacetals and nitroenediamines are interesting synthons and readily synthesized through the reaction have been summarized in Scheme 2. The most common method of synthesizing these compounds is the condensation of nitromethane 1 with carbon disulfide in the presence of KOH in ethanol solvent that makes compound 2. The reaction of compound 2 and dimethyl sulfate generates the nitro ketene dithioacetal-1-nitro-2,2-bis(methylthio)ethylene 3 that is a precursor in the synthesis of nitroenamine derivatives. The reaction of 3 with various amine (one equivalent or excess amounts) obtains the corresponding mono substituted 4 or keten aminals 5. Also, the elimination of two molecules of R¹SH from 1,1-bis (methylthio)-2-nitroethene 3 in reaction with diamines affords cyclic nitro-ene-1,1-diamine 6 (Scheme 2).^{7,8}

Work in the field of heterocyclic ketene aminals (HKAs) prior to 2014 was reviewed by Wang⁶ and in current review, we will investigate the relevant examples of heterocyclic ketene aminals containing nitro groups. This review summarizes the recent progress in heterocycle synthesis from 2012 to 2021. Its aim is to give an overview of the rich reactivity of nitroenediamines in multi-component reactions. This review is divided into two significant parts according to reagent and divided into subsections based on catalytic and non catalytic pathways for further clarification.

2. Nitroenediamine derivatives in heterocyclization

In this section, the reaction of cyclic and acyclic nitroenediamine have been described especially focusing on some

Scheme 1 Structure of nitro-1,1-enediamines and N-methyl-1-(methylthio)-2-nitroethenamine.

important mechanisms. Since cyclic nitroenediamine is obtained from reactions 1,1-bis(methylthio)-2-nitroethene and diamines, these reactions are also investigated in this section.

2.1. Catalysts-assisted approaches

RSC Advances Review

of (*Z*)-*N*-methyl-1-(methylthio)-2-nitroethenamine **5** with 3-formylchromone **7** achieved the azaxanthone derivatives **10** in good yields (up to 88%). Mechanistically, $In(OTf)_3$ promotes the Henry reaction of 3-formylchromone **7** with *N*,*N*-dialkyl-2-nitro-ethene-1,1-diamine **5** to generate intermediate **8**. In the following, the removal of water makes the intermediate **9** which undergoes 6π -electrocyclization to afford the final product **10** (Scheme 3).

Xiao and coworkers reported the silver-catalyzed synthesis of 2-(pyridin-3-yl)-chromeno[2,3-d]pyrimidine derivatives **12** *via* electrocyclization cascade reaction of 3-cyanochromone **11** and 1,1-enediamines 5 under reflux in 1,4-dioxane for 48 hours. Importantly, one C–C bond and three C–N bonds were formed, and one bond was broken in one-pot organic transformation (Scheme 4).¹⁰

Based on proposed mechanism, the nucleophilic Michael addition of nitroenediamine 5 with 3-cyanochromone 11 forms the intermediate 12. The imine–enamine tautomerization of 12 and further intramolecular 1,2-addition involving the primary amine leads to cyclic intermediate 14. Water removal and ring opening of intermediate 15 is promoted by silver carbonate to afford intermediate 16. Finally, the electrocyclization reaction of intermediate 16 with another 3-cyanochromone molecule 11 gives intermediate 17 which undergoes a 1,3-migration of hydrogen to obtain 2-(pyridin-3-yl)-chromeno[2,3-d]pyrimidines 18.

A valuable and efficient reaction of isatins **19** and 1,1-enediamines **5** catalyzed by NH₂SO₃H to synthesize corresponding multisubstituted quinoline-4-carboxamides **26** was reported by Yan and co-workers (Scheme 5).¹¹ Mechanistically, the aza-ene reaction of EDAMs **5** with isatine **19** gives the intermediates **20**. Then, tautomerization followed by intramolecular cyclization makes intermediate **22**. Intermediate **22** is converted into intermediate **24** *via* two ring-opening reactions. The primary amino groups of intermediate **24** attacks the imine ion to produce the intermediate **25** which then undergoes a cyclization reaction and tautomerization to produce **26**.

In 2021, Yan and colleagues disclosed the cascade reaction of the (*E*)-3-(2-oxo-2-phenylethylidene)indolin-2-one derivatives 27 and cyclic and acyclic EDAMs 5 and 6.¹² Applying acyclic EDAM substrates 5 in this reaction led to formation of 4-(2-oxoindolin-3-yl)-1*H*-pyrroles 28 *via* the selective nucleophilic attack of the amine on the more electron-deficient carbonyl (ArC=O) of compound 27 rather than the amide group (NHCO). The R1 group greatly affected the yields of 28, such that electron-withdrawing groups manifested higher yield of the products compared to electron-donating groups (Scheme 6).

The selective Michael addition of cyclic enediamine **6** to the unsaturated double bond of (E)-3-(2-oxo-2-phenylethyl-idene) indolin-2-one derivatives **27** in the presence of Cs_2CO_3 as the base at room temperature after 12 hours makes α -carboline **34** in excellent yields. To the surprise, the methodology for the same reactants in a longer time after 48 hours obtained the more stable α -carbolines **35**. Herein, tautomerization followed by intramolecular cyclization provides intermediate **31** that is

$$R^{1} \longrightarrow R^{1} \longrightarrow R^{1$$

transform into 34 under oxygen and losing two water molecules (Scheme 7).

Yan *et al.* in 2019, explored the DBU-promoted tandem reaction of different Morita–Baylis–Hillman (MBH) acetates **36** with the different EDAMs **5** to access fully substituted-2-amino pyrroles **39**. The results revealed that the electron-withdrawing group (F and Cl)-substituted of the MBH acetates can achieve a higher yield than the electron-donating group (MeO) and the reaction with *N*-phenyl EDAMs and *N*-alkyl-EDAMs gives higher yields than *N*-benzyl-EDAMs (Scheme 8).¹³

The α -C of EDAMs 5 begins the nucleophilic Michael addition to MBH acetates 36 that is accompanied by the elimination of the acetate group through an S_N2' mechanism to generate

intermediate 37. Imine–enamine tautomerization of intermediate 37 and further intramolecular aza-Michael addition promoted by DBU results in intermediate 38. Finally, aromatization by elimination of HNO_2 yields fully substituted 2-aminopyrroles 39.

Li *et al.* investigated the effect of 2,2,2-trifluoroethanol catalyst on the Mannich-like reaction of β -nitroenamines 6, amines 41, and aromatic aldehydes 40. TFEA was added to establish the hydrogen bond with aromatic aldehydes to increase its electrophilicity (Scheme 9).¹⁴

Hasaninejad *et al.* reported the preparation of pyrrolo[1,2-a] pyrimidine derivatives **28** *via* the reaction of bromoacetophenone **43** and 2-nitroethene-1,1-diamines **6** in the presence of K_2CO_3 (Scheme 10). The aza-ene reaction between bromoacetophenone **43** and 2-nitroethene-1,1-diamine **6** gives intermediate **44**, which is tautomerized and subsequent intramolecularly cyclized to produce **45**.

Shao and coworkers prepared bridged heterocycles 53 from one-pot reaction of ninhydrin 46, malononitrile 47, and nitroendiamine 6 in high yields (Scheme 11).¹⁶

Knoevenagel condensation of malononitrile 47 with ninhydrin 46 forms intermediate 48 that undergoes Michael addition of the nitro ketene aminal (NKA) 6 to give intermediate 49. The chemoselective nucleophilic attack of the NH of the resulted intermediate 50 at the carbonyl function affords intermediate 51. Then, *O*-cyclization and tautomerization of imino group to amino group of 51 could lead to fused oxa-aza[3.3.3]propellanes 53.

Scheme 7 Site-selective synthesis of highly functionalized 2,10-dihydro-1*H*-imidazo[1',2':1,6]pyrido[2,3-*b*]indoles **34** and pyrroles **35**.

Scheme 8 DBU-promoted tandem reaction of (MBH) acetates 36 with the EDAMs 5.

The elimination of two molecules of R¹SH from 1,1-bis (methylthio)-2-nitroethene 3 in presence of diamine 32 affords cyclic nitro ene-1,1-diamine 6.8 Alizadeh's group developed an efficient route to synthesis of 1,4-dihydropyridine-fused-1,3-diazaheterocycle derivatives 58 by refluxing a mixture of 1,1-bis(methylthio)-2-nitroethylene 3, 1,*n*-diamine 32, arylaldehyde 54, and malononitrile 47 in ethanol and 10 mol% of piperidine as a basic catalyst (Scheme 12).¹¹

Rezvanian reported I₂-promoted reaction of aldehyde **61**, pyruvic acid **60**, aliphatic diamines **59**, and 1,1-bis(methylthio)-2-nitroethylene **3** in synthesis of 1,2,3,7-tetrahydroimidazo[1,2-*a*]pyridine-5-carboxylic acids **65** (Scheme 13).¹⁸

Deep eutectic solvents (DES) consist of halide salt of a quaternary ammonium or phosphonium cation with a hydrogen bond donor (HBD), for example, urea, carboxylic acids, or ethylene glycol. DESs could be used as drug solubilization vehicles for drug delivery research. DES also possess

R = H, CI, Br, CF_3 , NO_2 , CH_3 , OCH_3 , 3-pyridyl, 2-thionyl

several key characteristics as liquids to support a wide variety of substrates and enzymes.19 Shaabani and co-workers used the DES by mixing choline chloride (ChCl) and urea to activate the carbonyl and cyano groups in a domino four-component reaction to get fully-substituted naphthyridines 69 (Scheme 14).20

Catalyst-free approaches 2.2.

A novel approach was developed for the synthesis of 2-amino-4coumarinyl-5-arylpyrroles 73 through a metal-free cascade reaction of arylglyoxal monohydrates 71, 1,1-enediamines (EDAMs) 70 and 4-hydroxy-2H-chromen-2-ones 72 (Scheme 15).21

A cascade reaction of 1,1-enediamines 5 with benzylidene-1H-indene-1,3(2H)-diones 74 in ethanol without any catalysts obtained the products 79. In this reaction, EDAM 5 attacks the C=C bond of benzylidene to promote the Michael addition reaction. The imine-enamine tautomerization of intermediate 75 makes 76. Then, the intermediate 77 is obtained through the enol-keto tautomerization of intermediate

Scheme 12 Synthesis of 1,4-dihydropyridine-fused-1,3-diazaheterocycle 58 via multi-component reaction.

Scheme 14 Synthesis of fully-substituted naphthyridine 69 through domino four-component reaction in deep eutectic solvent.

intramolecular cyclization of the intermediates 77 where the amino group attacks the carbonyl provides intermediate 78. Finally, water removal and oxidation of intermediate 78 affords target 79 (Scheme 16).²²

The aza-ene reaction of HKAs **6** and dioxopyrrolidines **80** without any catalysts in ethanol constructed imidazo[1,2-a]pyrrolo[3,4-e]pyridines **83** with good to excellent yield (Scheme 17).²³

Wang *et al.* devised the synthesis of perfluoroalkylsubstituted 2-oxopyridine-fused 1, 3-diazaheterocycles **88** *via* one-pot reaction of diamines **32**, ketene dithioacetals **3**, and 2perfluoroalkynoates **84**. Mechanistically, *in situ* cyclic ene-1,1diamine **6** participates in aza-ene reaction with 2-perfluoroalkynoate **84** to give **85**. An intramolecular imine-

enamine tautomerization followed by cyclization makes desired products 88 (Scheme 18).²⁴

Bayat *et al.* synthesized benzo[g]imidazo[1,2-a]quinoline-dione derivatives **95** from the multi-component reaction of ethylenediamine **32**, 1,1-bis(methylthio)-2-nitroethene **3**, 2-hydroxy-1,4-naphthoquinone **90** and aromatic aldehydes **89** (Scheme 19).²⁵ The proposed mechanism reveals that ketene aminal **6** from ethylenediamine **32** and 1,1-bis (methylthio)-2-nitroethene **3** attacks Knoevenagel adduct of the aldehyde **89** and 2-hydroxy-1,4-naphthoquinone **90** to afford intermediate **92**. The intermediate **92** under imine—enamine tautomerization and nucleophilic addition of the secondary amino group to the more reactive carbonyl group gives product **94**.

In 2017, Bayat's group applied cyanoacetohydrazide 96 instead of naphthoquinone 90 in similar pathway to produce imidazo[1,2-a]pyridine-6-carbohydrazide derivatives 98 at a short time (Scheme 20).²⁶

They also used this strategy in stereoselective synthesis of indenone-fused heterocycles **101** (Scheme 21).²⁷

In 2021, Ziyaei *et al.* utilized thioazlactones **102** and ketene aminals for the synthesis of bicyclic pyridone containing the dithiocarbamate group through domino amidation/intramolecular 1,4-addition-type/Friedel-Crafts alkylation reactions (Scheme 22).²⁸

3. (Methylthio)-2-nitroethenamine derivatives (NMSM) in heterocyclization

3.1. Catalysts-assisted approaches

An indium triflate-catalyzed reaction of (Z)-N-methyl-1-(methylthio)-2-nitroethenamine **4** with 3-formylchromone **104** achieved the 2-pyridone analogues **109** in good yields (up to

88%). As mentioned earlier, $In(OTf)_3$ promotes the Henry reaction of 3-formylchromone **104** with (*E*)-*N*-methyl-1-(methylthio)-2-nitroethenamine **4** (NMSM) to give intermediate **105**. Water removal makes intermediate **106** that undertakes *N*-cyclization, followed by chromone ring opening to provide **108**. At sequence, the elimination of MeSH and $In(OTf)_3$ affords the target **109** (Scheme 23).9

Perumal *et al.* developed a novel procedure in spiroxindoles **115** νia domino Knoevenagel condensation/Michael addition/intramolecular *O*-cyclization reaction of isatins **110**, pyrazoles **111**, and (*E*)-*N*-methyl-1-(methylthio)-2-nitroethenamine **4** in the presence of InCl₃ as catalyst (Scheme 24).²⁹

Rong and co-workers established copper-catalyzed construction of various isoxazolines **122** through the 1,3-dipolar cycloaddition reaction of styrene derivatives **116** and 4*H*-1,2-oxazete **118** *in situ* resulting from *N*-alkyl(aryl)-1-

(methylthio)-2-nitroethenamine 4.³⁰ The tautomerization and combination of substrate 4 with CuCl invited by the amino group generates intermediate 117 that smoothly transforms into intermediate 118. Elimination of methanethion from intermediate 118 makes intermediate 4*H*-1,2-oxazete 119 which yields 1,3-dipolar cycloaddition reaction with olefin 116 to obtain target 122 (Scheme 25).

Perumal *et al.* applied 4-hydroxy-1-methylquinolin-2(1H)-one **123** in Knoevenagel condensation domino reaction of aldehydes and *N,S*-methylacetal in catalytic amount of ZnCl₂ (Scheme 26).³¹

ZnCl₂ catalyst was also used in the synthesis of novel 2-methyl-6-(methylamino)-5-nitro-4-(4-aryl)-4H-pyran-3-carboxylate derivatives 132. This domino, one-pot reaction was performed for β -ketoesters 131, aromatic aldehydes 130, and

chemistry and in the synthesis of heterocycles.³⁵ This approach was adopted for the synthesis of benz[4,5]imidazo[1,2-*a*]purine derivatives **144** *via* consecutive reduction/auto-aromatization/ heterocyclization of 2-aminobenzimidazoles **142**, aromatic aldehydes **143**, and *N*-alkyl-1-(methylthio)-2-nitroethylene-1-amines **4** refluxing in *n*-BuOH for three hours in the presence of 10 mol% [BMIM][BF₄] (Scheme 30).³⁶

In 2012, chromen-5-ones **149** and pyrano[3,2-*c*]chromen-5-ones **147** were synthesized through tandem reaction of NMSM **4**, aromatic aldehydes **145**, and 4-hydroxycoumarin **148** or

dimedone **146** in the presence of catalytic amount of piperidine in ethanol (Scheme 31).³⁷

In 2018, Khan and colleagues reported the similar reaction of cyclic-1,3-diketones, aromatic aldehydes, and NMSM in catalyst-free neat condition at 110 $^{\circ}$ C to generate 4*H*-chromen-5-one derivatives.³⁸

Microwave irradiation facilitated the reaction of aromatic aldehyde **150**, 4-hydroxy-6-methyl-2-pyrone **151** and *N*-methyl-1-(methylthio)-2-nitroethenamine **4** to produce pyrano[4,3-*b*] pyran-5-one derivatives **152**. Ammonium acetate catalyzed the

reaction in ethanol and the microwave power higher than 200 watts decomposed the substrates (Scheme 32).³⁹

N-Methyl-1-(methylthio)-2-nitroethenamine **4**, aromatic amines **154**, and phenylglyoxal monohydrate **153** reacted in the presence of 10 mol% of iodine as catalyst. Both electron donating and weak withdrawing groups on aromatic amines except for nitro group gave desired products **120** in excellent yields (Scheme 33).⁴⁰ At first, the reaction between aromatic amines **154** and phenylglyoxal monohydrate **153** leads to the imine **155** that is activated in presence of molecular iodine. Mannich type reaction between iodine activated imine **155** and NMSM **4** generates intermediate **156** which undergoes intramolecular cyclization to afford **158**.

Prakash Rao and Parthiban developed an easy route to highly functionalized hexa-substituted 1,4-dihydropyridines.41 They used one equivalent of aldehydes 159, two equivalents of NMSM 4, and 10 mol% of 2-aminopyridine as catalyst refluxing in ethanol (Scheme 34). Mechanistically, at the first step, benzaldehyde 159 reacts with aminopyridine to make the iminium ion **160.** The reaction of the iminium ion **160** with one equivalent of NMSM generates intermediate 161, which quickly rearranges to the more stable intermediate 162. One more unit of NMSM reacts with intermediate 162 to generate intermediate 163 and 2-aminopyridine. Finally, an intramolecular elimination of methanethiol from 163 gives dihydropyridines 164. A similar designed to synthesize N-methyl-1,4approach was dihydropyridine derivatives in good yields under microwave irradiation without any solvents within 10 minutes.42

Aza-Michael annulation of 2-nitromethylene thiazolidine **165** with suitable Michael acceptors **166** using K_2CO_3 as the base afforded tetrahydrothiazolo[3,2-a]pyridinones **170** in good

yields (Scheme 35).⁴³ Based on proposed mechanism, in the presence of K_2CO_3 , 2-nitromethylene thiazolidine **165** forms nitronic acid salt intermediate **167** by tautomerization. Next, Michael addition of **166** with the nitronic acid **167** gives iminoketene intermediate **168**. Then an acylation of imine nitrogen followed by HCl removal results in ring closure and affords thiazolopyridinones **170**.

In 2015, Perumal *et al.* recorded the synthesis of 3-nitro-N-aryl/alkylthiophen-2-amines through the reactions of α -nitro-ketene N,S-alkyl amino acetals 4 and 1,4-dithiane-2,5-diol 171. Mechanistically, 1,4-dithiane-2,5-diol 171 is decomposed in the presence of K_2CO_3 to generate 2-mercaptoacetaldehyde 172. The nucleophilic addition of compounds 4 to the carbonyl of intermediate 172 followed by the addition of the thiolate anion makes the iminium intermediate 173. Addition of thiolate anion to the iminium functionality generates 174. Subsequent, elimination of methylmercaptan and water from 174 produces the thiophene derivatives 175 (Scheme 36).

In 2013, Paramasivan et al. applied a catalytic amount of piperidine in the domino four-component reaction of ethyl acetoacetate 176, hydrazine hydrate 177, substituted aldehydes 178 with the NMSN 4 under solvent-free conditions at 120 °C to achieve pyranopyrazoles derivatives 184 or chromenopyrazoles 183.45 They proposed two different mechanisms for targets. The condensation of ethyl acetoacetate 176 with hydrazine hydrate 177 gives pyrazolone 179 that undergoes Knoevenagel reaction with aldehydes to give Michael acceptor 180. The adduct 180 immediately undergoes Michael-type addition with nitroketene-N,S-acetal (NMSM) 4 to generate the open chain intermediate 181 or 182. If the aldehyde is salicylaldehyde, the oxygen attack of phenol occurs to get 182. Otherwise, the oxygen of pyrazolone attacks imine to generate new intermediate. Finally, the elimination of MeSH from consistent intermediates leads to chromenopyrazoles 183 or pyranopyrazoles 184 (Scheme 37).

diisopropylethylamine(DIPEA) refluxing in ethanol generated the 1,4-dihydropyrano[2,3-c]pyrazol-6-amines *via* domino cyclization Knoevenagel condensation/Michael addition/tautomerism/intramolecular *O*-cyclization/elimination sequences.⁴⁶

3-Methyl-1-phenyl-1*H*-pyrazol-5-amine **187** in the presence of green catalyst, L-proline, enabled to react with *N*-methyl-1-(methylthio)-2-nitroetheneamine **4**, and different aldehydes **186** to produce *N*,3-dimethyl-5-nitro-1-aryl-1*H*-pyrazolo[3,4-*b*] pyridin-6-amines **193** in good yields (Scheme 38).⁴⁷ The reaction of aromatic aldehyde **185** with L-proline generates the iminium species **187**. Then, the reaction between 3-methyl-1-aryl-1*H*-pyrazol-5-amine **186** and the iminium species **187**.

provides pyrazoloheterodiene **189** *via* intermediate **188**. Subsequently, the Michael addition of the nitroketene *N,S*-acetal **4** to **189** produces the intermediate **190**, which under intramolecular annulation affords the tetrahydropyrazolopyridine intermediate **191**. Elimination of methanethiol from **191** results in the formation of dihydropyrazolopyridine, **192**, which undergoes air oxidation to obtain pyrazolopyridine **193**.

Shao and coworkers prepared bridged heterocycle **195** from one-pot reaction of ninhydrin **46**, malononitrile **47**, and 1-(methylthio)nitroenamine **4** under mild condition (Scheme 39). The mechanism reaction has been mentioned earlier in Scheme 11.

Scheme 40 Synthesis of penta-substituted 4H-pyrans 197.

Scheme 42 Synthesis of pyrazolo[3,4-b]pyridine 206 and pyrano[2,3-c]pyrazole 207 from N-methyl-1-(methylthio)-2-nitroethen-1-amine 4.

The mixture of benzoylacetonitrile **196**, aromatic aldehyde **195** and (E)-N-methyl-1-(methylthio)-2-nitroethenamine **4** was refluxed in EtOH in the presence of triethylamine to obtain penta-substituted 4H-pyrans **197** in excellent yield (Scheme 40). 48

The reaction of *N*-methyl-1-(methylthio)-2-nitroetheneamine **4**, different aldehydes (benzaldehydes/heterocyclic aldehydes) **198** and 3-amino-1,2,4-triazole **199** under a mild condition in the presence of trichloroacetic acid (TCAA) as a Brønsted–Lowry acidic promoter generated *N*-alkyl-6-nitro-3,5-dihydro-[1,2,4] triazolo[1,5-*a*]pyrimidin-7-amine **202**. The reaction followed *via* domino Mannich-type reaction, *N*-cyclization, and oxidation. Anti-tumor activity of the synthetic library was also evaluated (Scheme 41).⁴⁹

In 2020, Rong *et al.* suggested a method for the synthesis of pyrazolo[3,4-b]pyridine **206** and pyrano[2,3-c]pyrazole **207** through multi-component condensation of benzaldehyde derivatives **204**, isatins **205**, *N*-methyl-1-(methylthio)-2-nitroethen-1-amine **4**, 3-aminopyrazole **203**, and p-toluene-sulfonic acid as the catalyst (Scheme 42).⁵⁰

Jeong *et al.* designed three-component reaction of 2-aminobenzimidazole **139**, aldehydes **208**, and (*E*)-*N*-methyl-1-(methylthio)-2-nitroethenamine **4**, in the presence of catalytic amount of *p*-toluenesulfonic acid (*p*-TSA) for the synthesis of *N*-methyl-3-nitro-aryl-benzo[4,5]imidazo[1,2-a]pyrimidin-2-amine derivatives **209** (Scheme 43).⁵¹

Recently, Li *et al.* synthesized chromeno[2,3-*b*]pyridine derivatives **211** through the annulation of 2-amino-3-formylchromones **210** and various 1-(methylthio)-2-nitroenamines **4** in the presence of CF₃SO₃H an acidic catalyst (Scheme 44).⁵²

3.2. Catalyst-free approaches

The multi-component coupling reaction of 2-hydroxy-1,4-naphthoquinone **212**, aromatic aldehydes **213** and (*E*)-*N*-methyl-1-(methylthio)-2-nitroethenamine **4** led to 2-(methylamino)-3-nitro-4-aryl-4*H*-benzo[*g*]chromene-5,10-diones **214** in excellent yields (Scheme 45).⁴⁶

The synthesis of dihydroxyoxoindeno[1,2-*b*]pyrrole derivatives **217** carried out by the simple reaction of ninhydrin **215**, *N*-

methyl-1-(methylthio)-2-nitroethenamine 4, and aromatic amines 216 in ethanol without any catalyst at room temperature (Scheme 46).53 The spatial relationship between two hydroxy groups was confirmed through NOE studies that revealed the desired 3,8-cis configuration of the substituents on the pyrrole ring.

A catalyst-free three-component reaction using naphthalene-2-ol 218, aromatic aldehydes 219 and (E)-N-methyl-1-(methylthio)-2-nitroethenamine 4 in water-ethanol medium was reported by Jeong and co-workers, leading to a highly functionalized *N*-methyl-2-nitro-aryl-1*H*-benzo[*f*]chromen-3amine derivatives 220 in excellent yields (Scheme 47).54

Novel tetrahydro-2*H*-thiazolo[3,2-*c*]pyrimidines 227 developed via microwave-mediated Mannich cyclization. The reaction of 2-(nitromethylene)thiazolidine 221, formaldehyde 223,

and various aliphatic or aromatic amines 222 in water using microwave irradiation and conventional heating was investigated. Higher yields and shorter reaction time obtained using microwave (Scheme 48).55

Conclusion

Nitro-1,1-enediamines (EDAMs) and N-methyl-1-(methylthio)-2nitroethenamine (NMSM) have been applied as versatile synthetic building blocks to synthesize all sorts of heterocycles or fused heterocycles. Relevant contributions of the last ten years with respect the catalysts and catalyst-free approaches have been reviewed. Among these contributions, novel polymeric catalysts and green multi-component reactions for constructing all kinds of biologically active heterocycles have וומת
