31 **Abstract**
32
33

34 A sensitive assay for detection of HIV-1 p24 antigen with inductively coupled plasma mass
35 spectrometry (ICP-MS) was developed by biotin – streptavidin (BA) system and gold nanoparticle
36 (Au NPs) based immunoassay. In this immunoassay, p24 antigen was firstly captured by
37 immobilized anti-HIV-1 p24 monoclonal antibody. After the immunoreactions with biotinylated
38 anti-p24 polyclonal antibody and Au NPs - labeled streptavidin, a diluted HNO₃ (5%, v/v) was
39 used to dissociate Au NPs, which was then introduced to the ICP-MS for measurements. Under the
40 optimized conditions, the calibration graph for p24 antigens was linear in the range of 7.5–75 pg
41 mL⁻¹ with a detection limit of 1.49 pg mL⁻¹ (3σ, n=5). The relative standard deviation (RSD) for
42 three replicate measurements of 37.5 pg mL⁻¹ of p24 antigens was 3.7 %. Other proteins, such as
43 human IgG, human HSA, human CEA and human AFP did not obviously interfere with the assay

1 Introduction

Human immunodeficiency virus (HIV) infection, which causes acquired immunodeficiency syndrome (AIDS) in humans, is considered pandemic by the World Health Organization (WHO).¹ Two closely related types of HIV, designated HIV-1 and HIV-2, have been identified. HIV-1 has a higher toxicity than HIV-2 and is by far the most common cause of AIDS. Detection of HIV-1 p24 antigen will reduce the diagnostic window between the time of human immunodeficiency virus (HIV) infection and laboratory diagnosis than detection of anti-HIV antibody. Therefore, detection of HIV-1 p24 antigen in serum or plasma is one of the traditional methods for early diagnosis of HIV-1 infection.

Several methods have been developed to determine p24 antigen, including boosted enzyme-linked immunosorbent assay (ELISA),²⁻⁵ real-time immuno-polymerase chain reaction (IPCR),⁶ magnetic immuno-chromatography (MICT),⁷ immunosensor,^{8,9} biobarcode amplification (BCA) assay^{10,11} and colorimetric detections with naked eyes,¹² etc. Among these, ELISA is the most common method for the detection of HIV-1 p24 antigen due to its specificity, simplicity, and low cost over various instrumental methods.¹³ However, the conventional HIV-1 p24 ELISA is relatively insensitive and, thus, has limited clinical usefulness. The biotin-streptavidin (BA) system, which is based on the high affinity of streptavidin for biotin (affinity constant= 10^{15} mol⁻¹), offers the possibility of improving the sensitivity of immunoassays, which makes ELISAs more effective.¹⁴ Streptavidin binding to biotin is specific enough to ensure that the binding is directed only to the target of interest. Biotin is a small molecule (244.31 Da) that, when introduced into biologically active macromolecules, in most cases does not affect their biological activity, e.g., enzymic catalysis or antibody binding.¹⁵ Thus, the BA system has been introduced into enzyme

1 immunoassays by most commercial ELISA kit for p24 antigen determination. Nonetheless, the
2 BA-ELISA method remains time-consuming and is often limited by a moderate sensitivity.

3 Element tagged immunoassays combined with inductively coupled plasma mass spectrometry
4 (ICP-MS) detection have become an emerging technique in the analysis of bio-samples.^{16,17}
5 Compared with traditional immunoassays, ICP-MS linked immunoassay deals with
6 element-tagged instead of radio isotope-tagged or enzyme-conjugated antibodies, making it free of
7 radioactive isotope or toxic enzyme substrate reagents.¹⁸ In the past years, several reports on
8 ICP-MS linked immunoassay using element - labeled reagents for the detection of various
9 biomolecules had been published. For example, Eu³⁺,¹⁹⁻²² Ru²⁺,²³ Lanthanide²⁴⁻²⁶-chelate antibody
10 conjugates had been used to develop both direct competitive and non-competitive immunoassays.
11 Another distinguishing feature of ICP-MS linked immunoassay is that high sensitivity could be
12 easily obtained by the use of the nanoparticles (NPs) tag instead of metal ions, due to large
13 quantities of detectable atoms in each NPs tag.^{27,28} The nanomaterials that have been used in
14 label-based immunoassays by ICP-MS include metal NPs (e.g. Au,^{27, 29-33} Ag), semiconductor NPs
15 (quantum dots (QDs), e.g. PbS,³⁴ TiO₂³⁵) and so on. Moreover, the ICP-MS linked immunoassays
16 also enables multiplexed and absolute quantification of proteins based on elements or NPs
17 labeling,³⁶⁻⁴¹ etc.

18 In this work, we developed a sensitive assay with BA system and Au NPs based
19 immunoassay by ICP-MS to detect HIV-1 p24 antigen in human serum. After a typical
20 sandwich-type immunoreaction among anti-HIV-1 p24 monoclonal antibody, p24 antigen,
21 biotinylated anti-p24 polyclonal antibody and Au NPs - labeled streptavidin, the captured AuNPs
22 were released and quantitatively detected by ICP-MS to indirectly determine the p24 antigen

1 concentration. The immunoreaction conditions of the dilute ratio of Au NPs - labeled streptavidin
2 and biotinylated anti-p24 polyclonal antibody were optimized. The specificity of the proposed
3 ICP-MS linked immunoassay was also investigated. Furthermore, it had also been applied to
4 measure p24 concentrations in artificially positive human serum samples. Concentrations of p24 in
5 human serums determined by the ICP-MS linked immunoassay were also cross validated with the
6 results of BA-ELISA.

7 **2 Experimental**

8 **2.1 Apparatus**

9 Gold measurements were performed using an ICP-QMS (Agilent 7700x, Tokyo, Japan). The
10 optimized parameters were listed in Table 1. The BA-ELISA results were obtained by measuring
11 the absorbance at 450 nm with the microplate reader (Multiskan MK3, Thermo, USA).

12 **2.2 Reagent and materials**

13 HIV-1 p24 antigen standards, biotinylated anti-p24 polyclonal antibody (origin concentration,
14 $1.5 \mu\text{g mL}^{-1}$) and 96-wells ELISA microplates were obtained from Wuhan Institute of Virology,
15 Chinese Academia of Science (Wuhan, China). Bovine serum albumin (BSA) was purchased from
16 Wuhan ChuChengZhengMao Science and Technology Engineering Co. Ltd. (Wuhan, China).
17 Tween 20 was purchased from Sigma–Aldrich Chemical Co. (St. Louis, MO, USA). Au NPs (15
18 nm) - labeled streptavidin (origin concentration, $400 \mu\text{g mL}^{-1}$) was purchased from Beijing
19 Biosynthesis Biotechnology Co. (Beijing, China). Human immunoglobulin G (IgG), human serum
20 albumin (HSA), human alpha-fetoprotein (AFP) and human carcinoembryonic (CEA) were
21 purchased from Usen Life Science Inc. (Wuhan, China). Unless otherwise stated, all the other
22 reagents used in this study were of analytical grade and obtained from Sinopharm Chemical

1 Reagent Beijing Co. Ltd. (Beijing, China).

2 Control blood samples from healthy persons were provided by volunteers of China
3 University of Geosciences (Wuhan, China). Serum samples were prepared from whole blood by
4 centrifuging at $10,000 \times g$ for 5 min in a serum separation vial and then stored as aliquots at -20°C
5 until analysis.

6 **2.3 Buffers**

7 The buffers and solutions used were:

8 (1) phosphate buffer (PBS): 8.0 g of NaCl, 3.58 g of $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$, 0.27 g of KH_2PO_4 and 0.2
9 g of KCl dissolved in 1 L distilled water (pH 7.4);

10 (2) coating buffer: 1.59 g of Na_2CO_3 and 2.93 g of NaHCO_3 in 1 L distilled water (pH 9.6);

11 (3) blocking buffer: 5% (w/v, g L^{-1}) BSA in PBS. The blocking solution was stored at 4°C and
12 used within a week;

13 (4) washing solution (PBST): 0.24 g of KH_2PO_4 , 2.9 g of $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$, 8.0 g of NaCl, 0.2 g
14 of KCl and 0.1% Tween 20 (v/v) in 1 L distilled water (pH 7.4);

15 (5) assay solution: 1% (w/v, g L^{-1}) BSA in PBS.

16 All buffers were prepared using water ($18.2 \text{ M}\Omega \text{ cm}^{-1}$) from a Milli-Q water purification system
17 (90005-02, Labconco water pro ps, Canada).

18 **2.4 Immunoassay Protocol**

19 The immunoassay was conducted by following the typical procedure for sandwich-type
20 immunoreaction (Fig. 1). Initially, a polystyrene 96-well microtiter plate was coated using 100 μL
21 of anti-HIV-1 p24 monoclonal antibody (diluted to $10 \mu\text{g mL}^{-1}$ with coating buffer) and incubated
22 at 4°C overnight. The unbound antibody was washed twice with 300 μL of washing solution

1 (PBST) to remove any unbound antibody, and the uncoated active sites of polystyrene substrate
2 were saturated with 125 μL of blocking buffer, in which BSA was used as a blocking agent to
3 minimize nonspecific adsorption of the antigens in the next step. 75 μL of diluted HIV-1 p24
4 antigen standards or serum samples and 25 μL of biotinylated anti-p24 polyclonal antibody were
5 pipetted into the wells together and incubated for 1 hour at 37°C. Unbound antigen and antibody
6 were removed from the plate with 300 μL of washing solution (five times). Then 100 μL of Au
7 NPs - labeled streptavidin was added to each well and incubation for 30 min at 37°C followed by
8 washing five times with PBST. At last, a 200 μL aliquot of 5 % (v/v) HNO_3 solution was added to
9 each well and shaking for 10 min to dissociate Au NPs from the immunoassay complex. Samples
10 were diluted to 4 mL with 5 % HNO_3 solution and introduced to the ICP-MS for determination by
11 peristaltic pump. The ^{197}Au intensities by ICP-MS were proportional to the concentrations of
12 HIV-1 p24 antigen in the sample. External calibration was used for the quantitative determination
13 of HIV-1 p24 antigen. In was used as internal standard element of Au to correct the fluctuation of
14 the instrument.

15 **3 Result and discussion**

16 **3.1 Effect of dilute ratio of Au NPs - labeled streptavidin**

17 During the sandwich immunoassay, the dilution ratio of Au-NPs labeled antibody is a key
18 factor affecting the detection sensitivity and the nonspecific binding of Au-NPs labels.⁴² In this
19 work, the influence of diluted ratio of Au NPs - labeled streptavidin on Au signal / background
20 intensity ratio (S/B) was investigated from 1:800 to 1:100 to obtain a favorable S/B value (Fig. 2).
21 The Au signal intensities were all investigated with a p24 antigen concentration of 75 pg mL^{-1} .
22 The Au background intensities had been tested as described in section 2.4, but using assay solution

1 instead of p24 antigen. It was found that the Au signal and background intensities were all
2 increased with the decrease of diluted ratio of Au NPs - labeled streptavidin. When the diluted
3 ratio was lower than 1:400, the Au background intensities were increased sharply and even higher
4 than the Au signal intensities. Au-NPs labels in high concentration are usually used to provide
5 high sensitivity for the high concentration range of analyte. However, nonspecific binding of
6 Au-NPs mainly derived from charge attraction, hydrophobic absorption and dative binding is
7 increased accordingly with the increase of Au-NPs labels concentration.³⁰ Thus, the background
8 intensities caused by nonspecific binding of Au-NPs in this paper also increases with the increase
9 of Au-NPs labels concentration. As shown in Fig. 2, the maximal S/B value was obtained at the
10 diluted ratio of 1:400. Therefore, a dilute ratio of 1:400 was chosen for the subsequent
11 experiments.

12 **3.2 Effect of dilute ratio of biotinylated anti-p24 polyclonal antibody**

13 The dilute ratio of the biotinylated anti-p24 polyclonal antibody was also optimized in Fig. 3.
14 The Au signal intensities were also investigated with a p24 antigen concentration of 75 pg mL⁻¹.
15 As can be seen that the Au signal intensities did not changed significantly with the diluted ratio of
16 biotinylated anti-p24 changed from 1:10000 to 1:100, but the Au background intensities with
17 assay solution instead of p24 was increased obviously with the decrease of diluted ratio of
18 biotinylated anti-p24 and the maximal ratio of Au signal intensity and Au background intensity
19 nearly 8 was obtained at the diluted ratio of 1:10000. The little decrease of Au signal at the small
20 dilution factors might be due to the experiment error. Considering the concentration of
21 biotinylated anti-p24 with higher diluted ratio may not be enough to cover the antigen, thus the
22 diluted ratio higher than 1:10000 was not investigated. Therefore, a diluted ratio of 1:10000 for

1 biotinylated anti-p24 was chosen for the later studies.

2 **3.3 Specificity of the immunoassay**

3 Four proteins in place of p24 antigen were tested with the same experimental procedure for
4 the specificity study (Fig. 4). These tested proteins are either abundant (eg. human IgG, human
5 HSA) or pathogenetic proteins (eg. human CEA and human AFP) in serum. The Au net-signal
6 intensities here were calculated by subtracting the Au background intensities with assay solution
7 from the Au signal intensities tested by different proteins. It can be seen that only the p24 could be
8 recognized in the sandwich-type immunoreaction. Human AFP, human CEA, human IgG or
9 human HSA did not significantly interfere with the determination of p24. It indicated our proposed
10 method had good specificity toward the target protein. Since the tested concentrations of the CEA,
11 AFP, IgG and HSA are close or higher to the concentrations in real healthy adult serum, this
12 ICP-MS linked immunoassay is capable of efficiently detecting p24 antigen in human serum.

13 **3.4 Analytical performance**

14 Under the optimal conditions, the analytical performance of the developed ICP-MS linked
15 immunoassay for the detection of p24 antigen had been carried out. As shown in Fig. 5a, the Au
16 signal intensities were linear with the concentration of p24 antigen in the range from 7.5 to 75 pg
17 mL⁻¹ with a correlation coefficient of 0.995. The precision for three replicate measurements of
18 37.5 pg mL⁻¹ p24 antigens was 3.7 % (the relative standard deviation, RSD). The detection limit
19 (LOD, 3 σ) of the developed method for p24 antigen was 1.49 pg mL⁻¹, where σ is the standard
20 deviation of five repetitive measurements of assay solution blank, corresponding to 4.65 amol of
21 absolute molar mass. In addition, the analytical merit of BA-ELISA for p24 antigen determination
22 was also studied in our work (Fig. 5b). The linear range of p24 antigen was found between 15 and

1 150 pg mL⁻¹ with a correlation coefficient of 0.997 and the LOD (3σ) of p24 antigen was 10.6 pg
2
3
4
5
6 mL⁻¹. The narrow linear dynamic range of BA-ELISA might be caused by the nonspecific
7
8 adsorption of HRP-labeled streptavidin occurred in the surface of microtiter plate. A comparison
9
10 of analytical performance of the present method with those of other methods for the determination
11
12 of p24 antigen is given in Table 2. The LOD of the ICP-MS linked immunoassay has around 1
13
14 order of magnitude improvement compared to that of amperometric immunosensor⁴⁴ and magnetic
15
16 immuno-chromatography⁷, although it is still higher than capacitive immunosensor⁸ and
17
18 plasmonic ELISA¹², indicated that this method still needs to improve sensitivity in biological
19
20 application.
21
22
23
24
25

26 3.5 Application

27
28
29 For the analysis of spiked serum samples by our proposed method, p24 antigen was spiked
30
31 into 5000 and 10-fold diluted healthy adult serums with assay solution and reached final
32
33 concentrations of 37.5, and 75 pg mL⁻¹, separately. Samples were analyzed in triplicate, and the
34
35 average signal response was used to calculate the p24 concentration from the standard curve
36
37 obtained prior to analysis. The percentage recoveries were calculated and were summarized in
38
39 Table 3. The better recoveries seen in the highly diluted samples may be indicative of a “washing
40
41 out” of matrix effects caused by nonspecific adsorption. Therefore, dilution was necessary for real
42
43 human serum determination.
44
45
46
47

48
49 The appropriate validation of a new analytical method is always the most crucial stage of its
50
51 development. The most valuable evaluating protocol is usually by comparing the developed
52
53 method with a different method that is commonly used in routine analysis or accepted as a
54
55 reference method for a given analyte and matrix⁹. In the present work, BA-ELISA was selected
56
57
58
59
60

1 since it is widely used in conventional p24 determination. However, since the patient serum with
2 AIDS was difficult to get in our lab, a preliminary evaluation of the validity of the proposed
3 ICP-MS linked immunoassay in artificially positive human serum samples was performed. We
4 added 30 ~ 80 pg mL⁻¹ p24 standards to normal human serum (diluted 10-fold) for a simulation
5 and both determined by ICP-MS linked immunoassay and BA-ELISA for a comparison. The
6 results were shown in Table 4. It was demonstrated that results from our method agreed well with
7 those from BA-ELISA, indicating that the present method could be applied to real clinical
8 samples.

9 **4 Conclusion**

10 A feasibility study for sensitive analysis of HIV-1 p24 antigen using a sensitive assay with
11 BA system and Au NPs - based ICP-MS immunoassay was demonstrated. Owing to the Au NPs
12 amplification process, the new detection approach achieved high detection sensitivity with 4.65
13 amol. Another advantage of the proposed strategy is its elimination of enzymatic reactions,
14 making it free of toxic enzyme substrate reagents. Moreover, the reagents are either biotinylated or
15 labeled with streptavidin; thus, the systems are easily adapted to detection of other biomolecules.
16 This ICP-MS linked immunoassay is promising for sensitive detection other proteins. Further
17 studies also can focus on how to decrease the nonspecific adsorption ratio of Au NPs and further
18 improve its detection sensitivity by using single particle detection mode.

1 **Figures and Tables Captions**

2 Fig. 1 Schematic diagram of the sensitive assay with BA system and Au NPs based immunoassay
3 for p24 antigen determination by ICP-MS.

4 Fig. 2 Effect of Au NPs - labeled streptavidin diluted ratios. (Concentration of p24 antigen and
5 dilute ratio of biotinylated anti-p24 polyclonal antibody, 75 pg mL^{-1} and 1:100; error bars in
6 the figure represent standard deviations of the results.)

7 Fig. 3 Effect of biotinylated anti-p24 diluted ratios. (Concentration of p24 antigen and dilute ratio
8 of Au NPs - labeled streptavidin, 75 pg mL^{-1} and 1:400; error bars in the figure represent
9 standard deviations of the results.)

10 Fig. 4 Specificity for the determination of p24 antigen using the proposed immunoassay.
11 (Concentration of p24, 75 pg mL^{-1} ; concentration of AFP and CEA, 100 ng mL^{-1} ;
12 concentration of IgG, 10 mg mL^{-1} ; concentration of HSA, 100 mg mL^{-1} ; dilute ratio of
13 biotinylated anti-p24 polyclonal antibody and Au NPs - labeled streptavidin, 1:10000 and
14 1:400; error bars in the figure represent standard deviations of the results.)

15 Fig. 5 Dependence of Au signal intensity with ICP-MS linked immunoassay (a) and OD value
16 with BA-ELISA (b) on p24 antigen concentration. (Condition of ICP-MS linked
17 immunoassay: diluted ratio of biotinylated anti-p24 polyclonal antibody and Au NPs -
18 labeled streptavidin, 1:10000 and 1:400; condition of BA-ELISA: biotinylated anti-p24
19 polyclonal antibody with no dilution.)

Table 1 Operating parameters for ICP-QMS.

| Parameter | Description |
|----------------------------------------------|-------------------|
| ICP RF power(W) | 1400 |
| Carrier gas flow rate (L min ⁻¹) | 0.69 |
| Diluted gas flow rate (L min ⁻¹) | 0.52 |
| Sample uptake rate (mL min ⁻¹) | 1.0 |
| Integrated time (s) | 1.5 |
| Acquisition time (s) | 9.7 |
| Sampling depth (mm) | 8 |
| Replicates | 3 |
| Isotope used | ¹⁹⁷ Au |
| Internal standard used | ¹¹⁵ In |

1 Table 2 Comparison of performances of the proposed ICP-MS linked immunoassay with other
 2 different approaches for the determination of p24 antigen.

| Approaches | Limit of detection (pg mL ⁻¹) | Ref |
|------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|-----------|
| Cytometric bead-based assay | 0.43 | 43 |
| Magnetic immuno-chromatography | 15–30 | 7 |
| Nanofunctionalized Surfaces in a Capacitive Immunosensor | 7.9×10 ⁻⁸ | 8 |
| Biobarcode amplification assay with europium NPs | 0.5 | 10 |
| Amperometric immunosensor with gold nanoparticles, multi-walled carbon nanotubes and an acetoneextracted propolis film | 6.4 | 9 |
| Plasmonic ELISA with the naked eye | 1×10 ⁻⁶ | 12 |
| Amperometric Immunosensor with polyelectrolyte /gold magnetic nanoparticle | 50 | 44 |
| ICP-MS linked immunoassay with Au NPs | 1.49 | This work |
| BA-ELISA | 10.6 | |

1 Table 3 Recoveries of spiked p24 antigens in serum samples.

| Dilution | p24 spiked (pg mL ⁻¹) | Recovery (%) |
|----------|-----------------------------------|-----------------------|
| 5000 | 37.5 | 92.0±8.0 ^a |
| | 75 | 96.6±10.2 |
| 10 | 37.5 | 119.6±3.6 |
| | 75 | 123.3±11.2 |

^a Standard deviation (n = 3).
