Direct synthesis of sulfenamides, sulfinamides, and sulfonamides from thiols and amines

 Yan Cao,^a Shahrzad Abdolmohammadi,^b ^{*b} Roya Ahmadi,^c Alibek Issakhov,^{de} Abdol Ghaffar Ebadi^f and Esmail Vessally ^g

Needless to say that organosulfur compounds with sulfur–nitrogen bonds have found various applications in diverse fields such as pharmaceuticals, agrochemicals, polymers, and so forth. Three major groups of such compounds are sulfenamides, sulfinamides, and sulfonamides which have been widely applied as building blocks in medical chemistry. Owing to their significant role in drug design and discovery programs, the search for and development of efficient, environmentally friendly, and economic processes for the preparation of the title compounds is of great importance in the pharmaceutical industry. Recently, oxidative coupling of thiols and amines, two readily available low-cost commodity chemicals, has emerged as a highly useful method for synthesizing structurally diverse sulfenamides, sulfinamides, and sulfonamides in a single step. Since this strategy does not require additional pre-functionalization and de-functionalization steps, it considerably streamlines synthetic routes and substantially reduces waste generation. This review will focus on recent advances and achievements in this attractive research arena.

Shahrzad Abdolmohammadi was born in Iran, in 1976. She received her BSc. degree in chemistry from Alzahra University (AU), Tehran, Iran, in 1999, her MSc. degree in organic chemistry from the Tarbiat Modarres University (TMU), Tehran, Iran under the supervision of Professor Issa Yavari in 2002 and her PhD degree in organic chemistry from the Tehran University (TU), Tehran,

Iran, under the supervision of Professor Hooshang Pirelahi and Professor Saeed Balalaie, in 2008. She is associate professor in East Tehran Branch, Islamic Azad University, Tehran, Iran. Her research interests include organic synthesis, heterocyclic synthesis, multicomponent reactions, nanocatalysis, organocatalysis, and synthetic methodology.

Dr Roya Ahmadi began her bachelor's degree in pure chemistry in 1992 at Shahid Beheshti University in Tehran, where she completed her master's degree in inorganic chemistry at Kharazmi University of Tehran (Teacher Training) in 2000 and received her PhD in mineral chemistry from Islamic Azad University, Tehran Science and Research branch in 2007. In the same year, he worked as an assistant

professor at Islamic Azad University, Imam Khomeini's Yadegar branch, and in 2014 he was promoted to associate professorship in the field of experimental and computational chemistry over the years, more than 115 articles in chemistry journals and 163 papers in national and international conferences as posters and lectures. Guidance and counseling of more than 75 graduate students, master's and doctoral degrees.

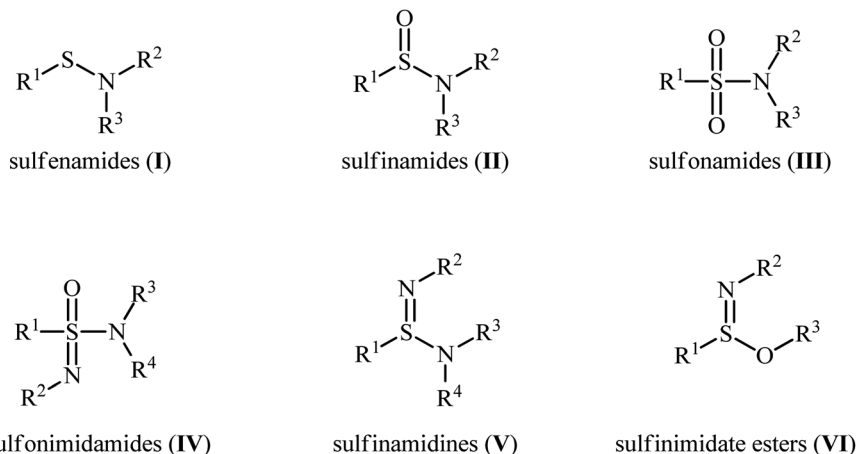

Fig. 1 General structure of sulfenamides (I), sulfinamides (II), sulfonamides (III), and some related compounds.

1. Introduction

Sulfenamides (Fig. 1, structure I) are versatile reagents that are used in the synthesis of various types of valuable organosulfur compounds such as sulfides,¹ sulfonimidamides,² sulfinamidines and sulfonimidate esters.³ Moreover, due to the high lability of their S–N bond, they are widely used as vulcanization accelerators in the rubber industry.⁴ In addition to their synthetic and industrial applications, sulfenamides are considered as a potential scaffold for promising antihypertensive, anticancer, and diuretic agents.⁵ In a similar way, sulfinamides (Fig. 1, structure II) are not only prevalent in a wide variety of natural products⁶ and commercially available chiral auxiliaries⁷ but also used as a valuable synthetic block in organic synthesis.⁸ Sulfonamides (Fig. 1, structure III) are another family of sulfur–nitrogen bond-containing organosulfur compounds that widely used as medicines,⁹ dyes,¹⁰ and plasticizers for fiber-reinforced composites materials.¹¹

The classical methods to synthesize *N*-sulfenyl-, sulfinyl-, and sulfonylamine derivatives involve the condensation of sulfenyl, sulfinyl, and sulfonyl chlorides, respectively, and amines.^{5a,12–14} However, corrosion and instability of most sulfenyl and sulfinyl chlorides, and some sulfonyl chlorides makes their handling troublesome.¹⁵ In order to bypass these limitations, over the years, several convenient strategies have developed.^{16–18} Among them, oxidative coupling of thiols and amines has been the focus of considerable attention due to its straightforward manner with high atom- and step-economy, providing concise and efficient methods for the fabrication of the titled compounds from easily available starting materials. In light of the increasing interest on this chemistry, we concluded that it was timely to summarize the available literature on this domain in a comprehensive review paper. In continuation of our preceding works on organosulfur chemistry¹⁹ and modern organic synthesis,^{20–26} we summarize here the most important contributions toward the synthesis of *N*-sulfenyl-, sulfinyl-, and sulfonylamines through the controllable oxidative coupling of

Dr Abdol Ghaffar Ebadi finished his doctoral degree in Environmental Biotechnology (Algology) from Tajik Academy of Sciences. Now he is a researcher in TAS in Tajikistan and faculty member at the Islamic Azad University of Jouybar in Mazandaran. Dr Ebadi published more than 400 scientific papers in qualified international journals and attended more than 50 international conferences. He has

cooperation with many research project teams around world such as China, Malaysia, and Thailand. His interests are Environmental Biotechnology, Biochemistry, Gene pathways in the phytoremediation processes.

Esmail Vessally was born in Sharabiyan, Sarab, Iran, in 1973. He received his B.S. degree in pure chemistry from university of Tabriz, Tabriz, Iran, and his M.S. degree in organic chemistry from Tehran university, Tehran, Iran, in 1999 under the supervision of Prof. H. Pir-elahi. He completed his PhD degree in 2005 under the supervision of Prof. M. Z. Kassae. Now he is working at Payame

Noor University as Professor in organic chemistry. His research interests include theoretical organic chemistry, new methodologies in organic synthesis and spectral studies of organic compounds.

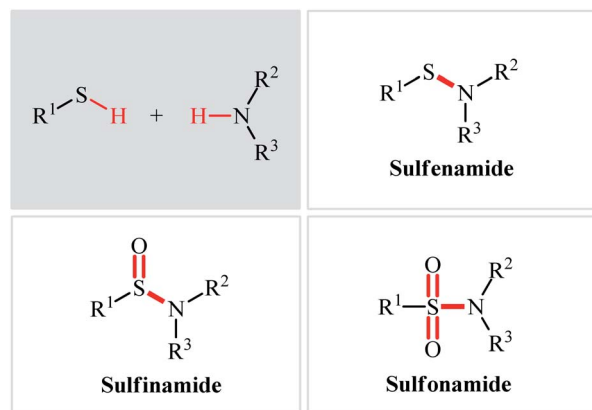

Fig. 2 Direct synthesis of sulfenamides, sulfinamides, and sulfonamides from thiols and amines.

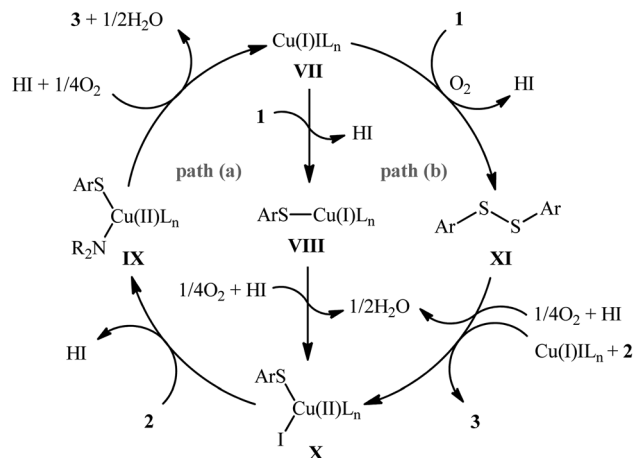

thiols and amines (Fig. 2), by hoping that it will inspire researchers to make further progress in the field.

2. Synthesis of sulfenamides

The possibility of synthesizing sulfenamides through the oxidative coupling of thiols and amines was first realized by Taniguchi in 2010.²⁷ By considering the coupling of *p*-thiocresol with *tert*-butylamine as the model reaction, the author carefully evaluated the reaction variables such as catalyst, ligand, and solvent. The optimal system was identified using inexpensive CuI catalyst in combination with 2,2'-bipyridine (bpy) ligand in DMSO at 60 °C, which gave the expected sulfenamide in a yield of 90%. Under the optimized conditions, various thiophenol derivatives **1** reacted efficiently with both aromatic and aliphatic amines **2** to give the corresponding sulfenamides **3** in 40–90% yields (Scheme 1). However, aliphatic and NO₂-substituted aromatic thiols failed to participate in this transformation. Regarding the scope of amines, aliphatic amines gave considerably higher yields compared to the aromatic ones. Intriguingly, when the reaction was performed under an oxygen atmosphere, instead of sulfenamides, the respective sulfonamides were obtained in modest to excellent yields. Furthermore, when the merge of PdCl₂ and CuI with bpy was applied as the catalytic system, it was found that the corresponding sulfenamides were selectively produced. The mechanism proposed to explain the formation of sulfenamides **3** starts with the

Scheme 1 Taniguchi's synthesis of sulfenamides **3**.

Scheme 2 Plausible mechanism of Cu-catalyzed cross-coupling of thiols **1** and amines **2**.

generation of ArS-Cu^IL_n complex **VIII** via oxidative addition of thiophenol **1** to the *in situ* generated active copper catalyst **VII**. Subsequently, oxidation of this intermediate with air oxygen gives ArS-Cu^{II}(I)L_n complex **IX**, which after reaction with amine **2** leads to the intermediate **X**. Finally, reductive elimination of this intermediate **X** in the presence of oxygen provides the expected product **3** and regenerates catalyst **VII** (Scheme 2, path A). In another possibility, oxidative coupling of thiophenol **1** forms diaryl disulfide **XI** that, after reaction with amine **2** produces the final product **3** and releases the intermediate **IX** (Scheme 2, path B).

Shortly afterwards, Wacharasindhu and co-workers further expanded the scope of this chemistry to heteroaromatic thiols using hypervalent iodine(III) reagent (diacetoxyiodo)benzene (DIB) as promoter and 1,8-diazabicyclo[5.4.0]-undec-7-ene (DBU) as base.²⁸ A relatively broad range of N-heterocyclic thiols **4** could be coupled with various primary and secondary aliphatic amines **5** by this method, and effectively furnished the corresponding *S*-heteroaryl sulfenamides **6** in fair to excellent yields (Scheme 3). However, thiols with the insufficient electrophilicity of the sulfur atom (*e.g.*, unsubstituted pyridine thiols) underwent competitive homocoupling side reactions, thereby provided a mixture of the desired sulfenamides and corresponding disulfides. Furthermore, sterically hindered (*e.g.*, *tert*-butylamine) and less nucleophilic amines (*e.g.*, anilines) were inert in this reaction and only disulfides were

Scheme 3 DIB-promoted S–N coupling of N-heterocyclic thiols 4 with amines 5.

Scheme 4 Proposed reaction mechanism for the formation of S-heteroaryl sulfenamides 6.

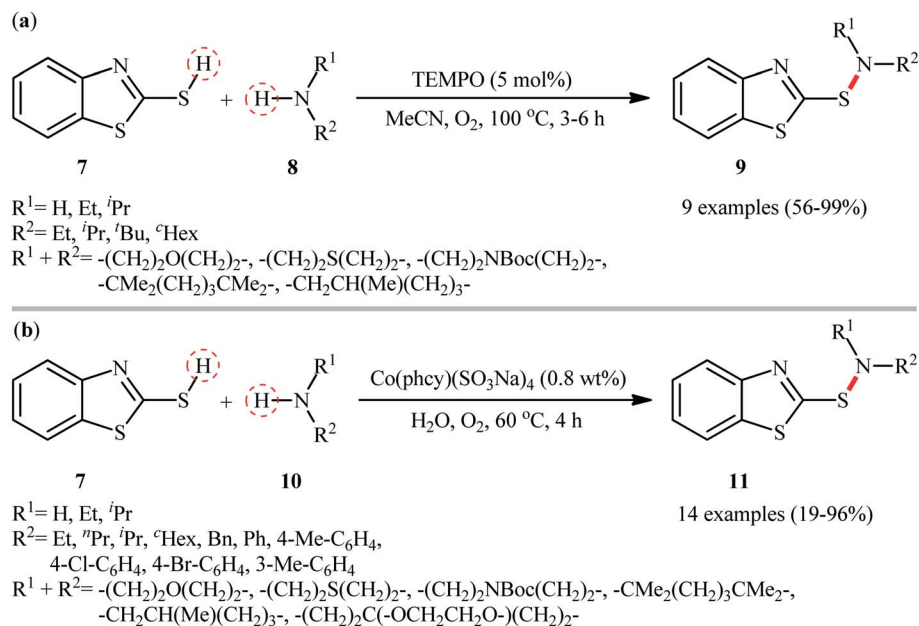

isolated using these nucleophiles. Based on the previous literature report, the authors proposed two possible pathways for this transformation as depicted in Scheme 4. The thiol **4** reacts with DIB to form the reactive key intermediate **XII**, followed by the nucleophilic attack on the sulfur atom by the SH-group of another molecule of thiol **4** with the removal of acetic acid and iodobenzene resulting in the disulfide intermediate **XIII**, which undergoes reaction with amine **5** to form the target product **6** and sulfide anion **XIV**. Finally, simple ligand exchange of DIB reagent with the anionic intermediate **XIV** regenerates the key intermediate **XII** (Scheme 4, path A). In another possibility, the direct nucleophilic substitution of intermediate **XII** with amine **5** affords the final product **6** (Scheme 4, path B).

At the outset of 2017, a straightforward and environmentally approach for the synthesis of 2-benzothiazolesulfenamides **9** by the reaction between 2-mercaptobenzothiazole **7** and alkylamines **8** was well reported by Yuan and colleagues (Scheme 5a).²⁹ This S–N bond formation reaction required 2,2,6,6-(tetramethylpiperidin-1-yl)oxyl (TEMPO) as catalyst and molecular oxygen as the terminal oxidant in acetonitrile. Various primary and secondary alkylamines including sterically hindered ones suitably participated in this reaction, delivering good to quantitative yield of the coupled products within 3–6 h. However, the applicability of arylamines was not investigated in this study. The reaction, moreover, appears to be limited to

unsubstituted 2-mercaptobenzothiazole. In the same year, utilized a conceptually similar strategy to fabrication of 2-benzothiazolesulfenamide derivatives **11** in acceptable yields employing phthalocyanine-tetra-sodium cobalt(II) sulfonate [Co(phcy)(SO₃Na)₄] as a reusable catalyst and water as the solvent (Scheme 5b).³⁰ Particularly, the reaction tolerated both alkyl and aryl amines **10**. However, like Yuan's work, except for 2-mercaptobenzothiazole **7**, other thiols, such as phenyl thiols failed in the system to provide the corresponding sulfenamides. Mechanistically, the authors speculated that the reaction proceeded through a free radical pathway *via* formation of a thiyl radical as the key step. Very recently, the group of Ko also synthesized a library of 2-benzothiazolesulfenamides (11 examples; 42–96% yield) in a similar manner employing dibenzyl azodicarboxylate (DBAD) as a promoter under ambient conditions.³¹ Similarly, 2-mercaptobenzoxazole was also compatible and reacted well with the same set of amines to give the corresponding 2-benzoxazolesulfenamides with slightly diminished yields as compared with the 2-mercaptobenzothiazole.

In 2018, Zeng and co-workers exploited the I₂/H₂O₂ catalytic system for cross-dehydrogenative coupling reaction between thiophenol **12** and anilines **13** with diverse steric and electronic properties, providing expedite access to a range of *N,S*-diaryl sulfenamides **14** (Scheme 6a).³² This metal free transformation

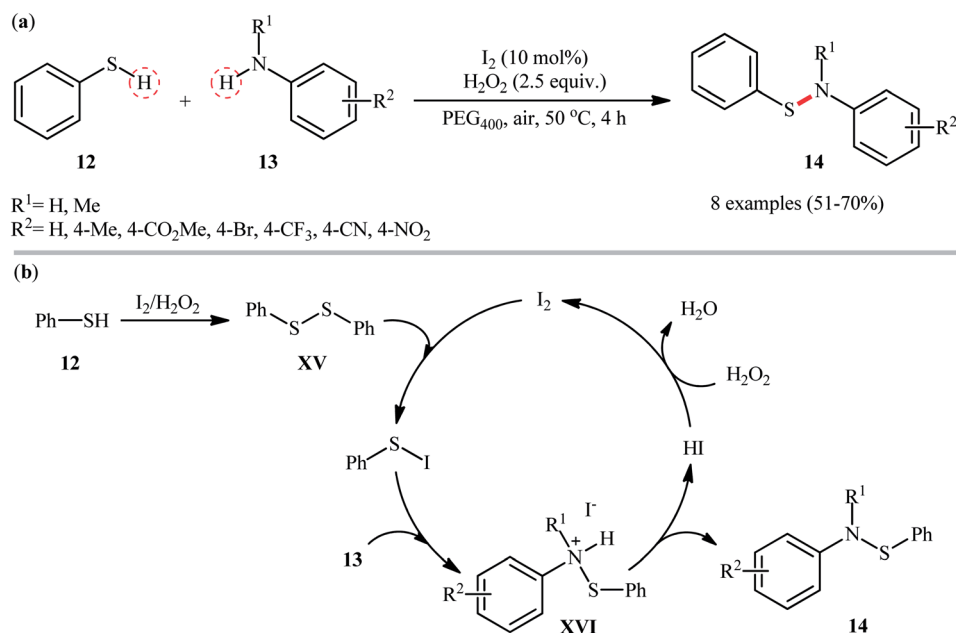

Scheme 5 (a) TEMPO-catalyzed oxidative coupling of 2-mercaptobenzothiazole **7** with alkylamines **8**; (b) synthesis of 2-benzothiazolesulfenamide derivatives **11** via co-catalyzed reaction of 2-mercaptobenzothiazole **7** with amines **10**.

was carried out in presence of 10 mol% I_2 and 2.5 equiv. of H_2O_2 in green and biodegradable polyethylene glycol (PEG-400) under mild conditions, tolerated various synthetically useful functionalities such as Br, CF_3 , CN, NO_2 , CO_2Me , and generally provided the respective products in moderate to good yields. Notably, this protocol also proved to be applicable to the use of sulfoximines as coupling partners. According to the author's proposed mechanism (Scheme 6b), presumably, the reaction initiated with the formation of the disulfide intermediate **XV** by

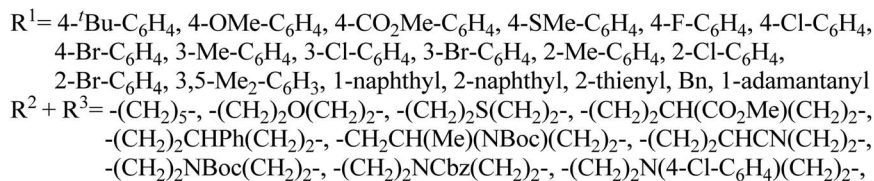

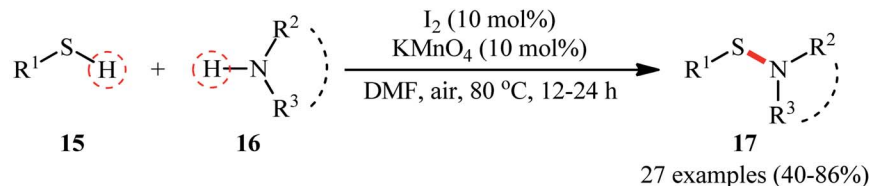

homocoupling of thiophenol **12**. Next, the disulfide reacted with I_2 and generated the active electrophilic species, Ph-S-I which was readily attacked by aniline **13** to provide ionic intermediate **XVI** and deliver the desired product **14** followed by a deprotonation process. Finally, hydriodic acid (HI) is oxidized by H_2O_2 to restore the I_2 catalyst.

Following these works, Zhang and Qian along with their co-workers used the I_2/KMnO_4 dual catalyst system for the oxidative dehydrogenation of thiols **15** and amines **16** to afford a wide

Scheme 6 (a) I_2 -catalyzed cross-dehydrogenative coupling of thiophenol **12** with anilines **13**; (b) putative mechanism for the formation of *N,S*-diaryl sulfenamides **14**.

Scheme 7 Zhang–Qian's synthesis of sulfenamides 17.

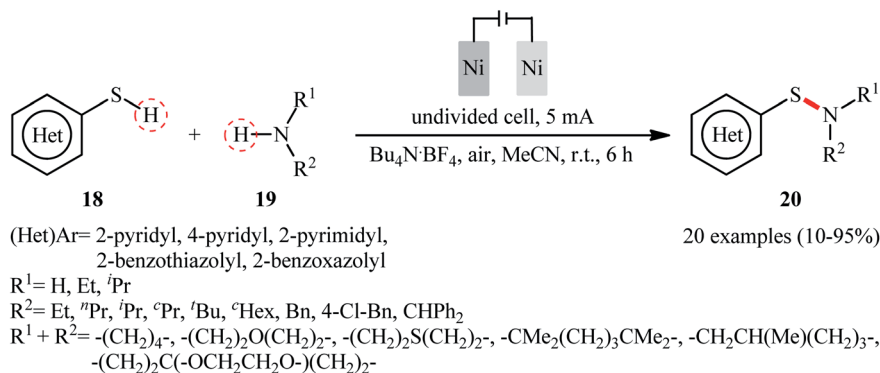

range of sulfenamides **17** in moderate to high yields (Scheme 7).³³ Although various aliphatic and (hetero)aromatic thiols with either electron-donating or electron-withdrawing substituents were well tolerated under the reaction conditions, the protocol was restricted to only secondary cyclic amines, however, the method was successfully explored for the synthesis of a drug-like sulfenamide with antihypertensive activity. It should be mentioned that under the identical conditions, due to their higher reactivity, the primary amines were converted to sulfenamides rather than sulfenamides. Based on the mechanistic studies conducted, the author speculated that the activated MnO_2 (generated *in situ* through the heating of KMnO_4 under O_2 atmosphere) was an electron transfer bridge for assisting iodine in completing the catalytic cycle.

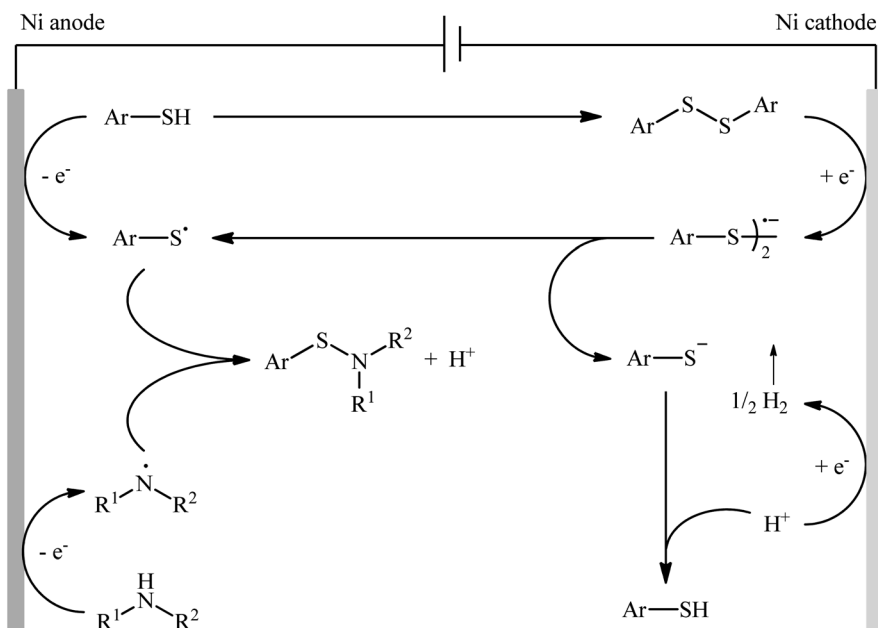

Recently, the Li–Yuan group developed an efficient electrochemical synthesis of *S*-heteroaryl sulfenamides **20** via dehydrogenative S–H/N–H cross-coupling of the corresponding heteroaryl thiols **18** with alkyl amines **19** under oxidant- and catalyst-free conditions.³⁴ Screening of various electrolytes such as $\text{Bu}_4\text{N}\cdot\text{Br}$, $\text{Bu}_4\text{N}\cdot\text{ClO}_4$, $\text{Bu}_4\text{N}\cdot\text{BF}_4$, and LiClO_4 , conclusively led to the use of $\text{Bu}_4\text{N}\cdot\text{BF}_4$ as the most promising electrolyte, whereas MeCN was found to be the most suitable solvent. The reaction was conducted in an undivided cell with inexpensive nickel foam electrodes under constant current of 5 mA at room

temperature for 6 h to deliver the coupled products in poor to excellent yields (Scheme 8). Concerning the substrate scope, the reaction is strongly dependent on the steric- and electronic-factors of amines. Sterically demanding amines such as diisopropylamine and 2,2,6,6-tetramethylpiperidine afforded less satisfactory results and less nucleophilic aryl amines completely failed in the system to provide the corresponding products. Notably, the reaction was scalable as exemplified by the formation of *N-tert*-butyl-2-benzothiazolesulfenamide on a 50 g scale (94%) while the Ni sheets could be reused. A plausible catalytic radical pathway for the formation of sulfenamides **20** was proposed as shown in Scheme 9. Initially, the thiyl radical and the amino radical were generated from thiol and amine, respectively, through the single-electron-transfer oxidation on the anode surface. Then the coupling of these radicals produced the desired product. Meanwhile, the thiyl radical underwent dimerization to form a disulfide that after the single-electron reduction at the cathode afforded the corresponding radical anion. Finally, the cleavage of this radical anion reproduced the thiyl radical and a thiol anion.

3. Synthesis of sulfinamides

In 2010, in the same paper describing Cu-catalyzed cross-dehydrogenative coupling of thiols and amines to

Scheme 8 Electrochemical oxidant- and catalyst-free synthesis of *S*-heteroaryl sulfenamides **20** through dehydrogenative S–H/N–H coupling of heteroaryl thiols **18** with alkyl amines **19**.

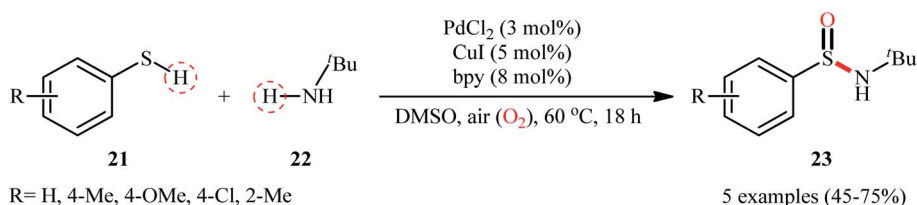

Scheme 9 A plausible mechanism for the reaction in Scheme 8.

sulfenamides, Taniguchi also utilized a dual Cu/Pd catalytic system towards the formation of sulfinamides from the same starting materials.²⁷ Detailed investigations revealed that the suitable conditions for this chemical transformation were: 5 mol% of CuI, 3 mol% of PdCl₂, and 8 mol% of bpy under open air in DMSO. Under optimal conditions, a small series of aryl thiols **21** were treated with *tert*-butylamine **22** for 18 h leading to the corresponding sulfinamides **23** in moderate to good yields (Scheme 10). However, in this preliminary work, only one amine was examined, without any substrate scope exploration. It is worth noting to mention that both CuI and PdCl₂ had a profound impact on this catalytic regime. As mentioned by the author, when the reaction was carried out with only the CuI-bpy catalyst, no sulfinamide is produced and sulfenamides are obtained selectively instead. Similarly, the palladium catalyst only also did not afford the desired sulfinamides and the corresponding disulfides are obtained as the major products under this regime. Unfortunately, no comment was made by the author regarding the plausible mechanistic course of this reaction.

With the aim of designing a more practical and substrate compatible protocol to sulfinamides through oxidative coupling of the corresponding thiols with amines, the innovative group

of Taniguchi also unveiled a highly efficient Cu-catalyzed dual S-H/N-H activation methodology to synthesize a relatively broad array of aryl sulfinamides **26** by combination of aromatic thiols **24** with various primary and secondary aliphatic amines **25** in a 6 : 1 mixture of DMSO and H₂O in presence of 5 mol% CuI as catalyst, 5 mol% bpy as a ligand, and 0.5 equiv. of NH₄PF₆ as additive under air at 70–80 °C (Scheme 11).³⁵ The results demonstrated that the reaction was equally efficient for both electron-rich and electron-poor aryl thiols. However, amino-group bearing aryl thiols turned out to be ineffective coupling partners under the standard reaction condition. Additionally, neither aliphatic thiols nor aromatic amines could react in this system. Based on a series of mechanistic studies conducted, the author proposed that through a similar catalytic cycle depicted in Scheme 2, a sulfenamide intermediate is initially formed which underwent further oxidation into the corresponding sulfinamide under the reaction condition. To shed light on the source of oxygen atom of the sulfinamide products, the author performed isotope labelling experiments with H₂¹⁸O which indicated that the oxygen atom originated from both water and molecular oxygen as a mixture of both ¹⁸O- and ¹⁶O-containing products in the ratio of 3 : 2, respectively, was formed.

Scheme 10 Synthesis of sulfinamides **23** from aryl thiols **21** and *tert*-butylamine **22** catalyzed by PdCl₂-CuI binary catalyst.

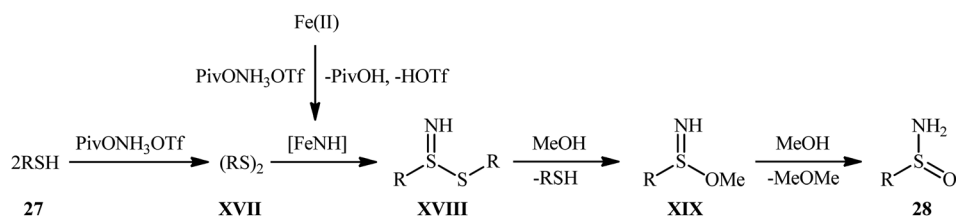

Scheme 11 Cu-catalyzed synthesis of aryl sulfinamides **26** from aryl thiols **24** and amines **25** in the presence of air.

Inspired by these pioneering works, very recently, Morandi and co-workers disclosed an interesting iron catalyzed protocol for the preparation of valuable unprotected sulfinamides **28** from thiols **27** and *O*-pivaloyl hydroxylamine triflic acid (PivONH₃OTf), where the hydroxylamine derivative was consumed as both oxidant and the aminating reagent in the presence of bidentate chelating bpy ligand.³⁶ The reaction was performed in the binary solvent MeOH/DCM with ratio 3 : 1 at room temperature, tolerated a wide variety of aliphatic, benzylic, aromatic, and heteroaromatic thiols, and accomplished the desired products in moderate to excellent yields within 16 h (Scheme 12). Notably, the author also showcased the synthetic versatility of this method through amino-oxidation of natural product derived 2-pinanthiol and thiocholesterol in modest yields. Intriguingly, mechanistic studies affirmed that the oxygen atom present in the resulting sulfinamides came from the alcoholic solvent and not from air oxygen. The plausible mechanism proposed by the authors for this transformation is illustrated in Scheme 13.

4. Synthesis of sulfonylamides

Drawing inspiration from the extensive research efforts on one-pot two step synthesis of sulfonylamides from the respective thiols and amines through oxidative chlorination of thiols to sulfonyl chlorides followed by reaction with amines,^{37,38} the first general report on the formation of three new bonds (two S=O and one S-N) in a single step to chemoselectively form sulfonylamide products was published by Feng and Wu in 2016.³⁹ In this investigation, a diverse array of *N*-unsubstituted sulfonylamides **30** were obtained in reasonable yields by reaction of various alkyl and aryl thiols **29** with aqueous ammonia in refluxing acetonitrile through the action of I₂/^tBuOOH (Scheme 14). A wide panel of synthetically useful functional groups such as -OMe, -SMe, -F, -Cl, -Br, -NO₂ were perfectly tolerated by this reaction, thus promising further modifications of the final products. In addition to ammonia, *tert*-butylamine was applied as well and gave the desired product in excellent yield. Based on the preliminary control experiments, the authors proposed

Scheme 12 Morandi's synthesis of unprotected sulfinamides **28**.Scheme 13 Proposed mechanism for Fe-catalyzed amino-oxidation of thiols **27**.

Scheme 14 I₂-mediated synthesis of *N*-unsubstituted sulfonamides **30** from thiols **29** and ammonia.

Scheme 15 Mechanism of reaction between thiols **29** and ammonia in the presence of I₂ and ^tBuOOH.

a plausible mechanism that consists of the following key steps (Scheme 15): (i) initial formation of thiyl radical **XX** through the one-electron oxidation of thiol **29** in the presence of I₂/^tBuOOH; (ii) oxidative combination of radical **XX** with ammonia to give sulfinamide intermediate **XXI**; and (iii) oxidation of sulfinamide **XXI** with ^tBuOOH to afford the final sulfonamide **30**.

Subsequently, Wei and Wang along with their colleagues unfolded the I₂O₅-mediated direct sulfonylation of amines **32** with arylthiols **31** to synthesize *N*-mono- and *N,N*-di-substituted sulfonamide derivatives **33** under metal-free condition (Scheme 16).⁴⁰ The reaction showed broad substrate scope, irrespective of whether electron-donating or withdrawing groups were at different positions of phenyl rings of aryl thiols, and both the aliphatic and aromatic amines exhibited good applications under standard conditions and afforded the target products in moderate to high yields. Moreover, a tolerance for 4-pyridinethiol (a heteroaromatic thiol) was also demonstrated. It should be mentioned that in the cases of primary amines, the use of stoichiometric amounts of DBU as the base was necessary because the yields of the corresponding products were

obviously reduced when only I₂O₅ was used in the reaction. The authors nicely highlighted the synthetic utility of their methodology by high yielding gram-scale synthesis of 4-tosylmorpholine (81% yield on 10 mmol scale). With regard to the mechanism (Scheme 17), the reaction initiates by the formation of disulfide **XXII** through the oxidative dimerization of the thiol **31**, followed by its oxidation with I₂O₅ to give benzenesulfonylthioate **XXIII** and molecular iodine. Next, the interaction of benzenesulfonylthioate **XXIII** with I₂ generates the sulfonyl iodide intermediate **XXIV**, which after nucleophilic substitution by amine **32** leads to the formation of the observed sulfonamide **33**.

In 2018, the Luisi-Bull group disclosed a novel route to synthesize primary sulfonamides **35** from thiols **34** through a one-pot NH and O transfer process using ammonium carbamate (NH₂CO₂NH₄) as the N-source and MeOH as the source of the O-atom as well as the reaction medium.⁴¹ The reaction was performed in the presence of a hypervalent iodine reagent at room temperature, and a series of (hetero)aromatic and aliphatic thiols showed good compatibilities under standard

conditions, affording corresponding *N*-unsubstituted sulfonamide products **35** in good to almost quantitative yields (Scheme 18). Notably, when the reaction was carried out in the presence of higher ammonia concentrations (4 equiv.) and reduced reaction times (3 h), related sulfonimidates were observed as the sole products, which was an interesting

example. Mechanistically, the reaction was speculated to be preceded through a similar type of mechanism as depicted in Scheme 13.

Recently, Noël and co-workers have made significant contributions to the field by developing a highly efficient electrochemical oxidative coupling of thiols and amines in a flow

Scheme 19 Electrochemical oxidative coupling of thiols **36** and amines **37** in flow cells.

cell without the use of a catalyst or external oxidizing agent.⁴² They showed that the treatment of thiols **36** with either primary or secondary amines **37** in an electrochemical flow microreactor with graphite anode and stainless steel cathode in a 3 : 1 mixture of MeCN/0.3 M HCl containing 0.01 M Me₄NBF₄ at room temperature produced the corresponding sulfonamides **38** in poor to high yields (Scheme 19). Although various alkyl, aryl, and heteroaryl thiols were well tolerated under the reaction conditions, the substrate scope of amines was merely limited to aliphatic derivatives. However, by adding an equivalent of pyridine as an electron-mediator, heteroaryl amines became competent coupling partners but attempts to expand the reaction scope to aniline derivatives were unsuccessful. Notably, carrying out this interesting electrosynthesis in a batch electrochemical cell was also possible but required higher loadings (100 mol%) of the supporting electrolyte and longer reaction times (24 h). The authors attributed the acceleration effect in flow to the shorter diffusion distances, the large electrode surface to volume ratio and the intensified mass transport due to the formation of hydrogen gas, which induces turbulence. A plausible mechanism based on several control experiments was

outlined in Scheme 20. The first step involves formation of a disulfide intermediate **XXV** from the thiol substrate **36** via anodic oxidation. Then electro-oxidation of amine **37** generates the aminium radical intermediate **XXVI**, which reacts with the disulfide **XXV** to form the sulfenamide **XXVII**. Next, two consecutive oxidation steps of the sulfenamide occurs and the targeted sulfonamide **38** produces via a sulfinamide intermediate **XXVIII**.

Very recently, the research group of Kamata and Hara explored the catalytic application of dual-functional high-surface-area β-MnO₂ (β-MnO₂-HS) nanoparticles for the direct sulfonylation of ammonia with thiols to synthesize primary sulfonamides.⁴³ Various aromatic and heteroaromatic thiols **39** have been reacted with aqueous NH₃ in the presence of a catalytic amount of β-MnO₂-HS under O₂ atmosphere to give (hetero)aryl sulfonamides **40** in moderate to high yields (Scheme 21). The reaction works better with electron rich than with electron poor substituents on the aryl thiols (88% yield for 4-OMe-substituted substrate compared to 58% for the 4-nitro derivative). It is worthwhile mentioning that the authors displayed the applicability of this methodology by performing

Scheme 20 Proposed mechanism for the electrosynthesis of sulfonamides **38**.

Scheme 21 β -MnO₂-catalyzed oxidative sulfonamidation of (hetero)aromatic thiols **39** with ammonia.

Scheme 22 Plausible mechanistic pathway for the reaction in Scheme 21.

a scale-up reaction, affording 89% of toluenesulfonamide. Unfortunately, no desired product was obtained when aliphatic thiols were employed under these reaction conditions. The recycling test established that the catalyst could be recovered by filtration and after washing with DMF and calcination reused for several consecutive runs without detrimental loss of catalytic activity. In this report, several control experiments and density functional theory (DFT) calculations were performed for the insight of the reaction mechanism, which indicated the formation of key thiosulfonate intermediate **XXX** in the catalytic cycle (Scheme 22).

5. Conclusion

Sulfenamide, sulfinamides, and sulfonamides are among the most important subclasses of sulfur–nitrogen bond-containing organosulfur compounds that are widely used in diverse fields

such as pharmaceutical, pesticide, and polymer industries. Owing to their versatile applications, the development of new, cost-efficient, and nearly waste-free methods for their preparation, from simple commercially available starting materials is highly desirable. As illustrated, the direct synthesis of titled compounds *via* condition-controlled oxidative coupling of thiols and amines, two inexpensive and readily available commodity chemicals, constitutes an atom-efficient and step-economic strategy, since no pre-functionalization of substrates is required. Despite remarkable achievements over the past few years in this appealing research arena, several great challenges still remain to be overcome. For example: (i) the majority of reported examples in the field have been performed in the presence of large amounts of molecular or hypervalent iodines. Therefore, development of related processes employing sub-stoichiometric amounts of other inexpensive reagents and catalysts will be attractive; (ii) the scope of amine partners was

largely limited to aliphatic ones, thus expanding of the substrate scope of these transformations to aromatic amines are necessary; and (iii) the number of reported examples in this chemistry (specially for the synthesis of sulfinamides) are narrow and there is a further need to study the scope and limitations of these reactions. We conclude this focus-review by hoping that it may serve as an inspiration for future studies and research on the field.

Conflicts of interest

There are no conflicts to declare.
